If a cardinal symptom of rickets is a blood low in calcium or inorganic phosphorus, then cod-liver oil or ultra-violet light, if they are specific antirachitic agents, might raise the concentration of these substances in the blood when administered to cases of rickets. That this is so has been shown by many investigators. Hess was the first to demonstrate a rise in inorganic blood phosphate in the blood of rachitic children following ultra-violet light treatment.

Iversen and Lenstrup and Howland and Kramer have shown that cod-liver oil has the same effect. McCollum and co-workers produced rickets in rats by giving diets (1) poor in phosphorus, and (2) poor in calcium. Other rats on the same diets had cod-liver oil in addition. Howland and Kramer examined the blood of these rats, and showed that (1) were low in inorganic phosphorus, and that (2) were low in calcium. Those rats having cod-liver oil had the normal calcium and inorganic phosphate blood contents. The histological structure of the bones follows, in a quite remarkable way the concentration of calcium and inorganic phosphorus of the blood.

It is well established, then, that rickets is a metabolic disease characterized by bones deficient in calcium phosphate, and accompanied by a diminished content in the blood calcium and of inorganic phosphate; that it can be cured both clinically and in experimental animals with certainty by administering cod-liver oil, and that the curative action is not due to vitamin A. It can also be cured with certainty by the action of ultra-violet light.

In what way do these two dissimilar agencies act? A consideration of the calcium and phosphorus metabolism may throw some light on this problem. The experiments of one of us (A. W.) described in this paper show that experimental rickets is accompanied by defective absorption of calcium and phosphorus from the intestinal tract and a very low uptake of these elements from the food supplied. Other observers, notably Paton, Sharpe, and Findlay, and Telfer have found that this is also the case with rachitic infants. Telfer has proved that the administration of extra calcium decreases the absorption of phosphorus, as shown by the urinary output; ingestion of fat also lowers the absorption of calcium, which is excreted in the faeces as calcium soaps. It is often urged against metabolism experiments that they are of too short duration and consequently are liable to gross errors. This cannot be said of the experiments described in this paper, in which the calcium and phosphorus metabolism was recorded throughout the experimental period of one month. In the rachitic rats A. W. did not get a negative calcium or phosphorus balance, and it is obvious that rickets is possible without the actual loss of calcium or phosphorus from the organism. Telfer finds that this is the case with rachitic infants. A. W.'s experiments show conclusively that both ultra-violet light and cod-liver oil greatly increase the absorption of calcium and phosphorus from the intestinal tract, and that this is followed by an increased retention in the skeletal structures as shown by bone analysis.

These results suggest very strongly that the primary seat of rickets is the gastro-intestinal tract—a view that is by no means new. In this connexion the experiments of Zucker, Johnson, and Barnett are of interest; when they made their rickets-producing diet acid it no longer produced rickets. They also examined the faeces of rachitic and non-rachitic rats, and found that the pH of the faeces of the non-rachitic rats was lower—that is, more acid—than those of rachitic rats on the same diet. If the intestinal contents are made acid it will prevent the formation of

insoluble calcium compounds, more especially the basic calcium phosphate, and so facilitate absorption of calcium and phosphorus in the blood stream. It has been suggested that the bacterial flora of the intestine may have some influence on absorption, and the experiments of Hill, Eidinow, and Colebrook, who have shown that radiation with ultra-violet light increases the haemobacterial power of both man and experimental animals, are of interest in this connexion. On the other hand, Korenchevsky was unable to produce rickets experimentally by bacteriological means. Findlay, who in a recent review of this subject is inclined to look with favour on the gastro-intestinal tract as the primary seat of rickets, was also unable to produce rickets by infecting the intestinal canal. He suggests that the digestive processes are impaired in rickets, and quotes some experiments that support this view.

The beneficial effects of exercise and a healthy open-air life are in great part due to a raised rate of metabolism, which must be followed by increased absorption from the intestinal canal, but, as shown later, rickets can be prevented in rats by ultra-violet radiation when these animals are kept in stagnant moist warm air. Mere increase of metabolism by exposure to cool open air does not suffice to prevent rickets on a deficient diet. A border-line diet, however, may well be made sufficient by increase of metabolism through exercise and open-air life.

It may be argued that the inability of the rachitic animal to maintain normal levels of calcium and phosphorus in its blood is not due to defective absorption but to other causes; these substances may be absorbed and excreted at a lower level owing to the animal's inability to make use of them—this inability to build up bone from supplies of material present being the root cause of rickets. The present state of knowledge does not permit us definitely to refute this view, but there is quite good evidence against it. The diets used for the experimental production of rickets do so by virtue of their deficiency either in quantity or in balance of calcium and phosphorus, and if this is rectified, then the animals do not develop rickets even if they are deprived of vitamins and radiant energy. Take, again, the experiments of McCollum and his co-workers on the effect of starvation in rickets; they took rats, which they rendered rachitic, and starved them for a few days and then killed them. Histological examination showed that the period of starvation was followed by a marked deposition of lime salts. The breakdown of the starving animal's tissues liberated phosphorus and calcium, which were promptly used to build up bone. This tends to show that it is not the rachitic animal's power of forming bone which is at fault, but lack of the raw materials—that is, calcium and phosphorus.

A consideration of the evidence given in this paper strongly suggests, then, that the primary cause of rickets is a low calcium and inorganic phosphate level in the circulating blood, and that this is due to defective absorption from the intestinal canal; and we favour this view.

Given the presence of adequate amounts of calcium and phosphorus in the blood, how does the animal convert this into bone? Until quite recently knowledge of this process was very meagre; recent work of Robison and his co-workers throws new light on it. They have shown that growing bones contain an enzyme capable of splitting hexose phosphates into inorganic phosphate. If strips of fresh young bone are placed in a solution of a calcium hexose phosphate insoluble calcium phosphate is deposited in the bone. Robison has further shown that a hexose phosphate is a normal constituent of blood, and that it occurs chiefly in the red blood corpuscle. This work is of great interest, but not yet advanced enough to consider specifically from the standpoint of the etiology of rickets. Both normal and rachitic bone contains the enzyme.

#### EXPERIMENTAL METHODS.

Our experiments were all carried out on rats. Except in a few early experiments when we used the diet described by McCollum, we used exclusively the diet 84 of Sherman and Pappenheimer. This has the following composition:

Patent flour	...	...	95 grams
Calcium lactate	...	...	2.5 "
Ferric citrate	...	...	2.0 "
Sodium chloride	...	...	0.1 "

It is a very deficient diet, poor in protein, practically free from vitamins, poor in phosphorus, and rich in calcium in relation to the phosphorus content. The ratio of calcium to phosphorus is about 4:1. It is the low phosphorus content together with the relatively large amount of calcium that gives this diet its rickets-producing character. The content of phosphorus, while being of itself ample, is not absorbed, and is mostly excreted in the faeces in combination with calcium. This diet produces, in fact, phosphorus starvation, and with the stock of rats we used it never failed to produce rickets.

The rats used were the ordinary white albino or black and white rats bred in the Institute. The stock rats were fed on oats principally, with occasional scraps from the canteen and a little greenstuff. The young rats were known to have a minimal quantity of vitamin A stored.

No attempt was made to select particular litters; the rats were taken at random from the Institute stock, animals weighing 40 grams, or as near as possible to this figure, being chosen. Each experimental group consisted of four animals; unless otherwise stated, they were kept in wooden boxes 14 by 9 by 7 inches, with perforated zinc lids; sawdust was used as bedding. The boxes were kept in a poorly lit room, what little sunlight there was having to come through plate-glass windows. The diet was mixed in the form of a stiff paste with distilled water and fed to the animals daily. Distilled water for drinking was supplied *ad lib*. Each rat was weighed at the commencement of an experiment and then weekly. The experimental period was twenty-eight days. At the end of this time they were killed and samples of blood taken for analysis; the bones were either examined histologically or they were x-rayed. In most cases the diagnosis was made from an examination of the x-ray photographs; although we used histological methods in some of the early experiments we found the x-ray method more useful. There is no doubt of the correctness of the diagnosis by this method, the difference between radiographs of rachitic and non-rachitic animals being most striking. Generally the inorganic phosphorus in the blood of the rats was determined at the end of each experiment, as was also the calcium and phosphorus of the bones. Young rats of about 40 grams weight put on the Sherman-Pappenheimer diet increase a little in weight and then decline, their appetite fails, and if left longer than twenty-eight days they usually die. If killed at the end of twenty-eight days gross rachitic changes are obvious and unmistakable. Typical experiments will be described here with the experimental results obtained.

We first tried the effect of exercise, or rather lack of confinement. One group of rats was kept in our standard size box, while another group was kept in a much larger box having four and a half times the floor and nine times the capacity of the small box. Rickets developed in all the rats in each box, so that confinement *per se* was not responsible for the development of the rickets.

Similar experiments were tried in which one group of animals were kept in the large box as before; but the box was kept out of doors for two hours daily, freely exposed to any winds and to a north sky in March, but shaded from direct sun. Rickets again developed. We are forced to the conclusion that exercise and open air but absence of direct sunlight have no specific antirachitic effect on young rats. It is possible that exposure to cold was disadvantageous. The influence of direct sunlight was next investigated. The rats were kept in the standard box, but at 12 noon each day they were transferred to an open-mesh wire cage and exposed on a high balcony facing south for two hours each day to whatever sun was available. The experiments were done in the spring and summer, but in this country the daily amount of sunlight is very variable. Our results varied, but we came to the conclusion that a minimum exposure of two hours to bright sun- or sky-shine five days a week was necessary to protect rats from rickets under the severe experimental conditions we have adopted in this research.

The rays emitted from two different known sources of ultra-violet light—the quartz mercury vapour and the open carbon arc—were next investigated. The rats were kept in their usual standard boxes; when it was necessary to expose them they were transferred to a small large-mesh wire cage and exposed for varying times to either the carbon arc or the mercury vapour lamp. The exposure varied from two hours daily to five minutes daily, and the distance from the lamps two to three feet. The quartz mercury lamp was a vacuum lamp taking 3.5 amperes at 200 volts. The carbon arc was a hand-fed lamp taking 5 amperes. The results are very striking provided the exposure is sufficient and not through glass, which filters out the active ultra-violet rays; radiations from this lamp will always prevent rickets from developing in rats on the standard diet we have used. The minimum exposure that will prevent rickets we found to be five minutes daily two feet from the mercury vapour lamp, and about thirty minutes

for the carbon arc at the same distance. We came to the conclusion that ultra-violet light is specific in its antirachitic effect. This will be emphasized in the experiments we are now going to describe.

This specific action of ultra-violet light seemed to us to conflict with the evidence of the incidence of rickets in tropical climates. Rickets is by no means unknown in the tropics, although it has been shown by chemical tests that the tropical sun is rich in ultra-violet rays. It is well known that the average mean temperature in the tropics is very high, and there is often present also a high degree of humidity. It seemed possible to us that this might influence in an adverse way the specific antirachitic effect of ultra-violet light, so we proceeded to investigate the question.

We first tried the effect of dry heat on young rats fed on a normal diet. A group of young rats was kept in standard boxes, the food consisting of the Institute stock diet—that is, whole cereals with a little greenstuff daily when available. From 5 p.m. to 9 a.m. the rats in their boxes were kept on the floor of the hot room, where the mean temperature was about 33° C. They spent the rest of the time in the outer hot room, where the mean temperature was about 23° C. This was continued for a period of twenty-eight days, when the rats were killed and examined for signs of rickets. No evidence of rickets was seen in any of the rats. Rickets, then, is not produced in rats fed on a normal diet and subjected to a high temperature for twenty-eight days. Another group of rats was fed on the same normal diet and kept in wire cages. These cages were suspended in large tanks with hot water just below but not touching the bottom of the cages. The water was regulated with a thermostat to keep a temperature of about 37° C. The rats thus lived in a very hot humid atmosphere. We found it very difficult to keep rats under these conditions, several dying of acute congestion of the lungs. A couple of rats lived under these conditions for forty days, and when killed they showed no signs of rickets. We came to the conclusion that, providing the diet is adequate, conditions simulating the tropics at their worst, but without any ultra-violet light, will not give rise to rickets in young rats.

We then subjected rats fed on our rickets-producing diet to conditions of dry heat described above, giving half of them thirty minutes' exposure to the carbon arc daily while the other half acted as controls. All the controls developed rickets, while none of the rats that had the light treatment showed any signs of rickets. Even under these adverse environmental conditions ultra-violet light prevents the development of rickets.

Other experiments have been carried out rather different from those described above, but with the same object in view. The usual groups of experimental and control rats were kept in standard boxes on the standard rachitic diet, but the actual light treatment was given under adverse conditions. The light from the carbon arc was by means of an aluminium reflector so focused on the rats as to expose them to tropical heat; other rats were chilled by keeping them for thirty minutes in the cold room and radiating them with the mercury vapour lamp actually in the cold room; yet others were radiated in the hot room with the mercury vapour lamp; further groups were radiated while they were kept cool by a powerful air blast or oppressed by moist heat. The results were always the same: the radiated rats, however adverse the conditions of radiation, were all free from rickets.

We consider these results in general highly significant, and feel justified in making the broad generalization that, provided an animal is supplied with food just sufficient to maintain life and a little growth and a bare minimum of the bone-forming elements calcium and phosphorus, then if ultra-violet light be supplied in adequate amount rickets will not develop however unfavourable the animal's environment be.

We carried out some other experiments on rather different lines.

A favourite remedy with animal dealers and keepers is flowers of sulphur; they say that it tones up animals out of condition and generally helps to keep their coats glossy. Its use combined with treacle as a spring tonic for children is traditional. We therefore tried this as an antirachitic substance. The usual group of four rats were given the standard rachitic diet to which was added 25 per cent. of flowers of sulphur (arsenic-free); at the end of twenty-eight days the rats were killed and examined—they showed no signs of rickets. This suggested an important addition to our scanty list of antirachitic agents, so the experiment was repeated. In the second experiment the result was negative; all the rats developed rickets. We have tried sulphur many times, but conclude that it fails to prevent rickets as often as it succeeds. We are convinced, then, that it can in about half the animals prevent rickets, but its action is uncertain.

In view of the partly favourable action of sulphur we thought

it of interest to see if a purgative or an intestinal antiseptic had any antirachitic effects. We used magnesium sulphate as being a typical neutral purge, and thymol as a typical intestinal antiseptic. We also tried arsenic, this substance being a well known tonic and mentioned also in the literature as being beneficial in cases of rickets in children. Magnesium sulphate and thymol proved to be useless as antirachitic agents, all the experimental rats showing severe rickets. The arsenic group of rats all showed rickets, but it seemed to be of a much milder type than that in the controls.

In view of statements made by others we thought it advisable to try the effect of the gases given off by the carbon arc and also of air that had been acted on by the mercury vapour lamp. There was, we found, no protection from rickets, even when the rats breathed the fumes of the irradiated air for a couple of hours a day.

It was suggested to us that the skin was a depot of antirachitic substance, and that ultra-violet light acted on the skin and stimulated it to pour this into the circulation. We therefore tried feeding animals on the antirachitic diet with portions of skin from freshly killed normal rats. The normal rats were killed and then skinned, as much hair as possible was removed, and weighed portions of the skin were administered daily to the experimental rats. The rats consumed the skin avidly. We gave amounts varying from 0.5 to 2 grams of fresh moist skin daily per rat. The results were negative; in fact, the rats that had the 2-gram ration of skin had grosser rickets than the controls.

We carried out an experiment with results that now seem highly significant in view of recent work. A group of rats were taken, and instead of radiating them daily they were given one hour's exposure to the mercury vapour lamp weekly, four exposures being given in all. This sufficed to protect them completely from rickets, and it seemed to us at the time that the light had actually synthesized something in the rat's organism which it was able to store and use subsequently.

In an attempt to gain further insight into the mechanism of the action of antirachitic agents, one of us (A. W.) studied the calcium and phosphorus metabolism of these groups of rats in special metabolism cages. Group (1) was fed on the standard rickets-producing diet only. Group (2) had the same diet with the addition of 0.2 c.c.m. of cod-liver oil per rat per day. Group (3) had no cod-liver oil, but the rats were radiated daily for ten minutes two feet from the mercury vapour lamp. The experiments lasted the usual period of four weeks. During this period the weekly intake of calcium and phosphorus was determined, also the calcium and phosphorus excreted in the urine and faeces. The difference between the intake and combined urinary faecal excretion gives the amount retained.

	Calcium.	Phosphorus.
The controls retained ...	0.37 gram	0.15 gram
The cod-liver oil group retained ...	0.58 "	0.26 "
The mercury vapour lamp group retained ...	0.51 "	0.20 "

These figures are the total retentions for each group of rats over the full experimental period of twenty-eight days. It will be observed that both cod-liver oil and ultra-violet light increase markedly the retention of calcium and phosphorus. In no case, however, was there any excretion of phosphorus in the urine. This means that in the rat under these conditions the inorganic phosphorus content of the blood is below the threshold level of the kidney both in the rachitic and non-rachitic animal. Calcification occurs when the inorganic phosphorus in the blood is below the threshold level of the kidney but higher than that of the blood of the rachitic rat as shown by direct blood phosphorus determinations. It will be remembered that the diet used is rickets-producing in virtue of its poverty in phosphorus. Let us now consider the calcium excretion: this being in considerable excess is excreted partly in the urine and partly in the faeces. The proportion of the total calcium excreted found in the urine was as follows:

In the controls ...	31.2 per cent.
In the cod-liver oil group ...	73.8 "
In the ultra-violet light group ...	65.7 "

While in the controls or rachitic rats only one-third of the total calcium excreted finds its way into the urine, two-thirds being excreted in the faeces, in the cod-liver oil and ultra-violet light-treated rats which are free from rickets, the figures are reversed—two-thirds of the calcium is excreted in the urine and one-third in the faeces. These figures strongly support the view that the antirachitic body in cod-liver oil and radiant energy in the form of ultra-violet light both act in the same way in preventing rickets, and that this mode of action is a facilitation of absorption of calcium and phosphorus from the intestine into the blood stream.

It is interesting to note that it is not necessary to have a negative balance—that is, a greater excretion than intake—of calcium or phosphorus before rickets develops. So long as there is enough calcium and phosphorus absorbed to satisfy the minimal demand for ossification, rickets will not develop. When absorption falls below this level rickets develops.

Since these pages were written Steenbock and Black, and also Hess, have published papers claiming that rickets can be prevented in rats by radiating the diet with ultra-violet light. Steenbock and Black radiate the whole diet, and claim that feeding this to the animal prevents the development of rickets. Hess radiates an inactive oil—cottonseed oil—and claims that feeding a little of this with the daily ration prevents rickets.

Independent confirmation of this important work seems necessary, so we have carried out some experiments with that object in view. We adopted the technique we have used throughout this work. Four groups of rats were taken, each rat weighing about 40 grams. Group 1 were fed on Sherman and Pappenheimer's diet 84 previously described. The diet, after being made up into a stiff paste with distilled water, was spread on a clock glass in a thin layer and placed under a mercury vapour lamp twelve inches from the burner and radiated for half an hour. It was then given to the rats daily for twenty-eight days, when the rats were killed and x-rayed. They showed no signs of rickets.

Group 2 were fed on the standard diet, and in addition received 0.5 gram daily of an inactive linseed oil that had been radiated half an hour twelve inches from the mercury vapour lamp. Fresh oil was radiated for each day's ration. The rats were killed after twenty-eight days and x-rayed. They also showed no signs of rickets.

In Group 3 the patent flour portion of the diet only was radiated as described above; after mixing with the other constituents it was given to the rats. At the end of twenty-eight days these rats proved to be free from rickets.

Group 4 were fed on the standard diet, and in addition they received a daily dose of radiated hardened cottonseed oil. This oil, which is really a solid fat, is a commercial product that we have used for other experiments on account of its complete freedom from fat-soluble vitamin A. It is the liquid cottonseed oil of commerce that has been hardened by the technical process of hydrogenation. It was radiated in the following way: the oil was melted into a transparent quartz flask; this flask was attached to a slow-running motor and slowly rotated between two mercury vapour lamps, six inches from each lamp, and radiated for a period of eight hours. It was then given to rats of Group 4 in daily doses of 0.5 gram per rat. On killing the rats at the end of the twenty-eight days they all showed on x-ray examination severe rickets. This was surprising in view of the previous result with linseed oil. Two explanations are possible: (1) the prolonged period of radiation at a temperature of 40° to 50° C. had destroyed any active substance formed earlier; (2) the process of hydrogenation had destroyed in cottonseed oil a precursor or substance which, when aided by ultra-violet light, becomes active.

In Group 5 the calcium lactate, ferric citrate portion of the diet only was radiated for half an hour. The calcium lactate was radiated in the powder form, the ferric citrate and sodium chloride were dissolved in water so as to give a large surface for radiation. The radiated salts were then mixed with the patent flour and given to the rats in the usual way. The salts were radiated fresh daily. The rats were not protected from rickets. These results confirm the work of Steenbock and Black and Hess—that certain rickets-producing foodstuffs can be made antirachitic by radiation with ultra-violet light. Further investigations show that cholesterol, or a vegetable sterol, after radiation has very great antirachitic power.

Two other American investigators, McQuarrie and Kugelmass, have published a preliminary account of an investigation in which they claim to have got startling results. Briefly, their work consists in making antirachitic substances like cod-liver oil or egg yolk undergo a process of oxidation, and during this process they claim that radiant energy is given off that will darken a sensitive photographic plate through a quartz screen but not through a glass screen. In other words, antirachitic substances undergoing a process of oxidation give off ultra-violet light. We have repeated their experiments but are unable to confirm their results or substantiate their claims. We have made many experiments in many different ways with different antirachitic substances, but have been unable to act on the most sensitive photographic plates either through quartz or glass screens when these were so arranged as completely to protect the photographic film from vapour arising from the substances in question. We found that certain samples of fused quartz, after being irradiated by ultra-violet rays, were able to act on a photographic plate. The quartz was rendered phosphorescent, and we think this may possibly explain why

McQuarrie and Kugelmass obtained positive results through a quartz screen and not through glass.

## TWO DISEASES DUE TO FASHION IN CLOTHING:

### CHLOROSIS AND CHRONIC ERYTHEMA OF THE LEGS.

BY

F. PARKES WEBER, M.A., M.D., F.R.C.P.

#### I.—CHLOROSIS.

THOSE of us who were house-physicians at hospitals in London about 1890 saw much of chlorosis in girls and young women. Making blood counts in such cases and prescribing Bland's pills and other chalybeate preparations constituted a not inconsiderable part of the daily routine work on the medical side. Where are similar patients to be seen now? Did anyone suspect that the familiar features of chlorosis would ever almost completely vanish from the doctor's surroundings as they have? It is true that formerly in general practice countless troubles in women of all ages were attributed to "anaemia" without any blood count being made, and to doubt the correctness of the diagnosis was often to offend the patient. It is therefore quite natural that some modern physicians of a younger generation, experts in blood examination, especially those practising on the Continent, should question the alleged former frequency of chlorosis, suggesting that it was due to want of knowledge and insufficient or careless examination of the blood. But no one who was a house-physician in London about 1890 can admit the justness of such an accusation. Blood counts were made and the ordinary features of chlorosis were well known. Indeed, one could make the diagnosis with practical certainty when one passed girls and young women in the London streets, or even at the seaside, with the typical appearance of "green-sickness."

One remembers the characteristic pale, puffy face, the shortness of breath on climbing the stairs or other slight exertion, and, in the severer cases, obvious physical signs of cardiac dilatation. There were the out-patients who gave up their treatment at the hospital to take advantage of some charitable person's kind offer of a gratuitous holiday at the seaside. There they often tried to vie with their companions in "healthy" exercise and "enjoyment" of the open air, but with most unfortunate results. Chlorosis was certainly not due merely to insufficient food or want of open-air exercise. They soon returned to London and the hospital out-patient room, but in a condition far worse than when they left. They had lost during their holiday all that they had previously gained from the out-patient chalybeate treatment.

Some patients sought employment as cooks or helps in basement kitchens, so that they could avoid the frequent stair-climbing ordinarily required of domestic servants. In this way they escaped much of the dyspnoea on exertion, the "panting" on the stairs, and the "tea and bun" midday meal of many of the shop-girls of that period. They got plenty of meat, but often took very little green vegetables and fruit so as to save themselves from gastric flatulence—with the result that they increased their tendency to constipation, and often added to their other troubles recurring so-called "bilious attacks" and the kind of headaches largely due to intestinal autointoxication.

Psychasthenic and functional nervous symptoms in the more mentally active and (financially) "better-off" subjects

so often accompanied chlorosis that in private practice they came to be regarded as an essential feature of the disease, and such symptoms were frequently attributed to "anaemia" when there was no anaemia.

That chlorosis (the "chlorotic anaemia" of girls and young women) has greatly diminished or almost disappeared during recent times seems to be generally admitted by medical observers in England, the United States, and the European continent; but what was the cause of the disease, and why has it been passing away? Though various factors may have played a part, it seems now almost certain that the main exciting cause of the disease was the wearing of corsets, and that the gradual abandonment of tight-lacing has ultimately led to its almost complete disappearance. The anaemia of young women connected with mitral stenosis and hypoplasia of the heart and large blood vessels, to which Virchow<sup>1</sup> drew attention in 1872, was probably mostly not true chlorosis, and has not disappeared, but the patients have not the typical "puffy" appearance. It was perhaps O. Rosenbach<sup>2</sup> who, in 1895, first claimed that corsets were responsible for (true) chlorosis, and this opinion has been recently supported by Roch and G. Bickel<sup>3</sup> of Geneva, and T. Deneke<sup>4</sup> in Germany.

This explanation accounts for the following facts: (1) Typical chlorosis never occurred in boys. (2) Rather fat girls were more affected than thin girls; the former probably "squeezed themselves" more than the latter. (3) Prolonged rest in bed, where corsets were not worn, always made the patients better; it was, in fact, a chief method of treatment for bad cases. (4) Holidays at the seaside, with plenty of open air, often made the patients worse, probably because they overfired themselves and tried to look their best and thought that tight-lacing helped to make them more attractive. (5) Married life often had a good effect, probably in part because, at any rate in the poorer classes, it indirectly led to less tight-lacing. The male once captured, it was no longer so necessary to charm his eye with the slender waist which he had been trained to admire. (6) Chlorosis was absent (according to Deneke) amongst Persian and Japanese women, who did not use corsets. It was doubtless due to natural individual powers of resistance and compensation that chlorosis was not still more prevalent in the days when tight-lacing was customary.

## II.—CHRONIC ERYTHEMA OF THE LEGS.

A kind of chronic (indurative) erythema of the legs in girls and young women seems now to be becoming by no means very uncommon. It is usually admitted that true "erythema induratum" of Bazin is of tuberculous origin,<sup>5</sup> though perhaps the tubercle bacilli which give rise to it are not very virulent and the patients affected are fairly resistant to the graver forms of tuberculosis. Be this as it may, the form of erythema to which I am now referring is apparently not directly related to tuberculosis, and though it is a chronic indurative erythema of the legs in girls and young women—sometimes leading to diffuse thickening and scleroderma-like hardening of the skin and subcutaneous tissue—it does not, like true "erythema induratum" of Bazin, lead to the formation of nodules and ulcers, unless as the result of local injuries.<sup>6</sup> The patches of erythema, which, at least at first, are temporary, disappear or diminish during warm weather and rest in bed; they may, however, progress to a stage of red or cyanotic hard ("brawny") thickening of the skin and subcutaneous tissue, and may occasionally diffusely and symmetrically encircle the lower part of both legs. The condition may become so serious and threatening as to necessitate repeated rest in bed for a few days, and may prevent the patient from carrying on her work.

Cases which I believe belong to this class have been demonstrated at the Royal Society of Medicine quite recently by S. E. Dore and A. W. Stott<sup>7</sup> (I have myself had the opportunity of noting the progress in their case) and by H. MacCormac.<sup>8</sup> Amongst slightly earlier accounts is that by G. N. Meachen,<sup>9</sup> who described it as one of "persistent erythema of an erythromalgic type," apparently because the erythema and pain in the legs were relieved by assuming the horizontal posture.

That the condition is not yet recognized as a definite

syndrome with a special name of its own is testified by a recent paper by S. N. Vendel,<sup>10</sup> headed "Erythema," with a note of interrogation, to signify the uncertain nature and etiology of the erythema. He and his colleagues in Denmark have observed about 75 cases during the past five or six years. The thickening may be marked, extending from a little below the external malleolus upwards, and the anterior and exterior aspects of the legs are chiefly involved. The affected skin is red or cyanosed, as if it had been subjected to Bier's artificial passive hyperaemia. The thickened tissues do not pit on pressure with a finger; the local pallor induced by the pressure disappears at once when the finger is withdrawn. The limbs feel cold, and the patients may complain of pain, tenderness, paraesthesia, or a sensation of heaviness in them. The condition is bilateral and more or less symmetrical, and affects females whose ages are mostly between 14 and 20 years. According to Vendel the condition, though it exists throughout the year, is most troublesome in the cold season. In about one-third of his cases flat-foot was present. In one case superficial varicose veins were present, and in one varicose veins in the popliteal spaces. No treatment proved satisfactory in his series of cases.

It seems to me that in these cases there must be a condition of persistent local atony of the blood capillaries, such as has been observed by Otfried Müller, Parrisins, and others, by the help of the skin microscope, in certain conditions of the skin and mucous membranes. Indeed, some (not all) cases are associated with a "chilblain" or "weak" circulation; the defective circulation in the extremities may even amount to a condition of acrocyanosis. The patients are mostly fairly plump and there may be a kind of puffy fusiform swelling, not of the interphalangeal joints (as in some infective rheumatoid conditions), but of the phalangeal segments between the joints. In some cases menstruation has been delayed or scanty, with functional ovarian insufficiency or definite ovarian hypoplasia. Other cases have been associated with colonic stasis or intestinal autointoxication. H. MacCormac has suggested that the scanty covering of the legs now customary, by thin silk stockings only, from the upper edge of the boots or shoes to the lower border of the dress, is responsible for the erythema. S. E. Dore and some others support this view, and the condition did not attract medical attention before short dresses and thin silk stockings became generally popular.

If it be admitted that in certain persons a constitutional defect in the capillary circulation—a tendency to atony of the blood capillaries of the skin and subcutaneous tissues—may constitute a soil or basis favourable to the development of the true tuberculous "erythema induratum" of Bazin, one may suppose that in girls and young women with a similar constitutional capillary defect the local action of cold on the poorly clothed portions of the legs may give rise to more or less permanent atony of the superficial blood capillaries, leading in some cases to a red or cyanotic thickening of the affected skin and subcutaneous tissue. This would account for the temporary beneficial effect of warm weather and of a few days of rest in the recumbent position in a warm bed. An occasional relationship of intestinal autointoxication and sexual hypoplasia to defective capillary circulation in the extremities may likewise be admitted, but it is the action of cold as a local exciting cause that has mainly to be considered.

The reason why most girls and young women do not suffer from the local erythematous condition in question is doubtless that the cold is sufficient as an exciting cause only when it acts on the basis of a constitutional defect in the capillary circulation of the skin and subcutaneous tissue. Such a constitutional defect, first showing itself after puberty, might be allied to the constitutional basis which sometimes leads to true Bazin's erythema induratum. Similarly, as I have pointed out in the first part of this paper, it was probably only in girls and young women having another special kind of constitutional tendency (predisposition) that tight-lacing produced typical chlorosis. It would be interesting to ascertain whether the young subjects of chronic erythema in the legs ever develop true tuberculous erythema induratum of Bazin, and whether in later life they will tend more than others to develop hypostatic dystrophic

changes in the lower extremities, of the type of so-called "varicose ulcers," "varicose eczema," and "varicose pigmentation," associated or not with pronounced varicose veins.

## THE TREATMENT OF HAY FEVER.

BY

FRANK COKE, F.R.C.S.

In popular parlance the term "hay fever" is used very loosely to include all forms of paroxysmal sneezing. In this article hay fever refers solely to the affection due specifically to sensitization to the pollens. The majority of cases are due to the grass pollens, and recur with great regularity from the end of May to the middle of July. A few cases, due to sensitization to the tree pollens, commence in April or the beginning of May. The identity of these should be discovered by means of the dermal tests before the season commences.

Sweet-smelling flowers and those which are highly coloured have heavy sticky pollens and are fertilized by insects; their pollens are not air-borne, and so have little effect in causing hay fever. The scent of these flowers will often provoke paroxysms in hay fever patients, but this can be disregarded in planning the treatment, as when desensitized to the grass pollens the patient's sensitiveness to the smell of flowers will disappear.

## PREVENTIVE TREATMENT.

Sea voyages are effective, but sending patients to the seaside is of no use unless a guarantee can be given that the wind there will be from the sea. Avoidance of the pollen being, then, impossible, one of the following methods must be used to desensitize the patient.

(a) *Desensitization of the Patient by Small Doses of the Pollen.*—Judging by experience in desensitizing horse asthmatics, far greater trouble should be taken in using this method than is commonly observed. It would seem that we have to use up the patient's specific adzyme, as I have called it, by means of minute doses of the protein spread over a period of many months without at any time giving a large enough dose to excite the formation of more specific adzyme. The patient is tested with dilutions of the protein, and a dilution ten times weaker than that which gives an appreciable reaction on the skin is used. Starting with a dose of 2 minims of this, weekly or bi-weekly doses are given, increasing each dose by 1 minim until the next dilution containing ten times more pollen is reached. We do the same with this, gradually increasing the dose until a higher dilution is required. All this must be done very slowly, making frequent dermal reactions to see how the course of treatment is progressing. When the stronger solutions are used the doses should be increased very slowly indeed. It is essential that the dilutions used to treat the patient are actually those with which he has been tested; otherwise they are bound to vary in strength—first, because the grass flowers from which the dilutions are made, though duly weighed, may be wind-blown and so carry varying amounts of pollens; and secondly, because the strength may deteriorate considerably after it is made. The method of giving a few doses shortly before the hay fever season, and especially daily doses, may appreciably lessen the patient's hay fever, but for another reason: anti-anaphylaxis takes place. However successful this may be it fails, because it gives no protection for the next

season. Before we can say that the patient is cured we must not only obtain freedom from hay fever but from treatment as well.

(b) *Desensitization by Non-specific Methods.*—Probably any protein would effect this purpose, but the danger of the patient being sensitive to them is so great, especially in the case of horse serum, as to preclude their routine use. In my experience the "mixed coliform vaccine" originally suggested by Danysz is the most effective. Though an autogenous vaccine is undoubtedly preferable, heterogeneous mixtures may be used. These should contain some 40 per cent. of *Bacillus coli*, 40 per cent. of coliform variants, and 20 per cent. of intestinal streptococci. Doses varying from and rising from 20 to 1,000 million of these organisms are injected hypodermically, once or twice a week according to the nearness of the hay fever season. I have had several patients who have had a course of this treatment four years ago and who have passed through subsequent seasons without hay fever and also without the inconvenience of the yearly course of treatment. Treatment with this vaccine should be commenced in April and continued well into the hay fever season. But it is almost equally effective when given later in the season. It will often stop hay fever even when violently active, though the permanent desensitizing power is best conferred by the early course.

These two methods should not be used together, for the pollen injections will defeat the objects of the mixed coliform vaccine.

(c) *Medicines* are of very little use in controlling hay fever. The calcium salts are those most favoured. I find great value in the use of colloidal calcium, which should be given when the hay fever season is due to commence in 1/2 to 1 c.c.m. doses intravenously.

(d) *Cauterization* of the nose is very useful for two purposes. If on examination of the nose before the hay fever season commences we find that the turbinates are covered with boggy swollen mucous membrane, cauterization should be undertaken to reduce them by scarring. The other use of the cautery is to touch the mucous membrane lightly and destroy some of the nerve endings and so lessen the extreme sensitiveness present. This should be done over the turbinates on either side, and particularly on the septum anterior to the bony outlet of the nose. With a blunt probe other tender spots can be searched throughout the whole area. I am in the habit of doing this cauterization about the middle of May, thus allowing just sufficient time for healing before the season commences.

## SYMPTOMATIC TREATMENT.

(a) The patient should be placed in a cool dark room. The admittance of fresh air from the outside should be limited to the minimum, for the whole air is heavily laden with pollen. For the same reason the windows should be kept closed at night unless the warmth of the weather makes this impossible.

(b) The effect of the direct sunlight is so provocative of sneezing that dark glasses should be worn if the patient does not stay indoors. These should fit closely round the eyes, after the manner of motor goggles. Broad-rimmed hats and caps are often helpful.

(c) The patient is greatly assisted by taking steps to prevent the pollen passing on to the mucous membrane of the nose. Unfortunately, the worse the patient's hay fever is the more difficult it is to touch the nose without causing a paroxysm of sneezing. Simplest, perhaps, is a tube of vaseline with a long nozzle out of which sufficient can be squeezed just inside the nose. This can be pushed further up the nose by pinching that organ with the finger and thumb, assisted by sniffing it up. Liquid paraffin or olive oil may be used very frequently in a coarse spray.

(d) Various medicaments may be added to the paints and sprays to meet the symptoms. Adrenaline and menthol will constrict the blood vessels and so lessen the swelling of the mucous membrane, allowing the orifices of the various sinuses to regain their patency. Cocaine and its substitutes reduce the intense irritation of the nerve endings in the nose, and constrict the blood vessels, especially cocaine. Oily and greasy vehicles for these drugs soothe the mucous membrane and prevent fresh pollen getting to it.

(c) Similar drugs may be used for the eye symptoms. In educated people, who can be trusted not to use the drugs to excess, the instillation of a few drops of cocaine (4 grains) and adrenaline (3 drachms to the ounce) will not only help the eyes, but, by passing down the lacrimal duct, will also allay the trouble in the nose. Used in an atomizer these may be sprayed up the nose and also into the eyes. In prescribing these drugs some estimate must be made of how often the patient will use them and, more particularly still, the kind of spray he will use them in, likewise the viscosity of the ingredients of the solution used.

(f) A search should be made for any microbio invaders which are adding to the patient's discomfort.

(g) Considerable comfort is experienced by dipping the whole face into a basin of cool water at bedtime. If sufficient salt is added the eyes may be opened and washed in this. Keeping the lips and glottis closed some patients manage, by expanding the buccal cavity, to draw the solution into the nose and wash that at the same time. Such a washing often allows the patient to fall asleep with ease and comfort.

By these various methods much more can be done for the unfortunate sufferer from lay fever than was possible formerly.

## RECTAL INJECTION OF ETHER IN WHOOPING-COUGH.

BY

C. ELGOOD, B.M. OXFORD,

HOUSE-PHYSICIAN TO THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK.

MANY methods are used in the treatment of whooping-cough; among the many drugs belladonna, opium, and quinine seem to be the favourites. Recently x-ray treatment has been suggested in America<sup>1</sup> and in England.<sup>2</sup> Vaccine treatment has also been tried on many cases.<sup>3</sup> Ether was first suggested in 1914 by Audrain, whose results were published in 1920.<sup>4</sup> He used 1 to 2 c.cm. injected intramuscularly three times a day. Since then several other workers have published their results; Pannoyatou stated that the duration of the disease could be reduced to twelve days after starting treatment by a dose of 1.5 to 3 c.cm. of ether given intragluteally on alternate days.<sup>5</sup> Mason in America, who treated 26 cases in the same way,<sup>6</sup> had 60 per cent. cured and 24 per cent. definitely improved. He also tried ether by the rectum on four cases, using 6 c.cm. of a 40 per cent. solution of ether in olive oil. Half of these were successful and half failures.

Smith<sup>7</sup> has recently reviewed all the literature published since the war on the treatment of whooping-cough, but does not mention the rectal method of administering ether. It would seem that this is the first time that a large number of cases so treated has been put on record.

### MODE OF ADMINISTRATION OF ETHER.

It has been the custom to administer the ether by subcutaneous or intramuscular injection. This is undoubtedly the most rapid method, but it is very unsatisfactory for children between the ages of 2 and 12. An enema by the rectum is much more suitable. The enema is painless—only two cases in this series complained of abdominal pain, rapidly passing off, and the majority of children raise no objection to the repetition of the treatment. The only difficulty lies in getting a certain number of cases to retain it.

When ether was given by injection I always used the intragluteal route. The dose was 5 to 10 minims of the ordinary anaesthetic ether. For the administration of an enema I used a full-sized male rubber catheter, attached by a small glass tube to a larger-bored rubber tube with a funnel at the other end. The ether was mixed with an equal amount of olive oil, the dose given being 1 drachm of the mixture for every year of age. If anything an excess was given, and if the symptoms were severe and the enema well retained 1 or even 2 extra drachms were given. Before

administering the enema the skin round the anus was well smeared with vaseline and the catheter then passed up 3 to 6 inches. The ether mixture was passed into the funnel and allowed to flow into the rectum by its own weight. The rate of flow can be watched through the glass tube connecting the catheter to the tube. This also serves as a gauge to see whether there is anything left in the tube. When all the enema has been run in, the catheter is rapidly withdrawn and usually none leaks out. Ether appears in the breath about five minutes after the enema has been given and can be detected during the next twenty-four hours. It has never in this series caused any digestive upset or pulmonary trouble. In many cases it did not begin to have any beneficial effect till after the second administration, and in severe cases actually aggravated the symptoms at first.

I treated the first 25 cases with ether alone without drugs and the next 25 with ether and drugs; the latter improved so much more rapidly than those treated with ether alone that the remainder of the cases were always treated with both. Of drugs I tried phenazone, bromides, belladonna, iodine, and opium in various combinations. I met with successful results with all these drugs, but belladonna was the most generally successful. In the cases summarized in this article only four enemata or injections were given—in some cases one each day and in others on alternate days. There would seem to be no advantage in resting for forty-eight hours nor any need to limit the treatment to four doses.

### RESULTS.

After December 1st, 1924, all cases of whooping-cough coming to the casualty department were treated by ether. In this way the results of 86 consecutive cases can be recorded. Of these, 28 were treated by injection and 58 by enema. Of the former, 11 gave up the treatment before the course was completed, but, with the exception of 3, the results as far as they went were satisfactory. Three cases must be classed as failures, and the remaining 14 were successful.

Of those treated by enema 14 gave up the treatment owing to the parents' objections or because the child would not allow the administration of the enema. Of the remainder, 13 were failures and 31 successful. Of the children successfully treated, the earliest had been coughing for four days and the longest for more than four weeks. This case was a girl of 6 who had been coughing for about a month when first seen. She was having about forty attacks during the twenty-four hours, and vomited in nearly half of them. The appetite was very poor, and there were frequent attacks of epistaxis. The first two enemata contained 3 drachms of ether each, and the second two 3½ drachms. The breathing improved after the second, and the whooping completely stopped after the fourth. One week later the vomiting also stopped and the appetite improved. The child was putting on weight at the rate of an ounce a week, and reported satisfactory progress at every subsequent visit. No more epistaxis occurred after treatment was started.

In addition to these cases of pertussis treated in the casualty department, an outbreak among the in-patients enabled me to try the ether treatment on a number of cases under constant observation. Of these, 12 were treated by enemata and 5 by injections. Nine of the former were successful; the paroxysms were at once considerably diminished in number and violence, and ceased within a few days. Three were failures. Two of these patients were already under treatment for bronchopneumonia and the third for anterior poliomyelitis. The observations of the nursing staff bear out what the mothers reported to me in the out-patient department. Of those treated by injection 4 were successful and 1 a failure, though benefited.

I have had no success with ether as a prophylactic, though probably, if given when a suspicious cough commences, the disease will be aborted or rendered very mild. It is perhaps worth noting that the only cases in the ward which remained unaffected and were not given any prophylactic treatment were two cases of colic disease. They were in the ward when the original case was admitted, and at the time of writing, three months after the first "whoop" was heard, have no signs of the disease.

The total number of cases treated by mo with ether may be tabulated thus:

Method.	No. of Cases.	No Result.	Successful.		Failures.	
			No.	Per Cent.	No.	Per Cent.
Intramuscular ...	33	11	18	55.5	4	12.1
By the rectum ...	70	14	40	55.5	16	22.8
Total ...	103	25	58	55.5	20	19.4

In holding a case to be successful I have laid stress on the following points: (1) the number of attacks of paroxysmal coughing; (2) the violence of the coughing; (3) the number of times that vomiting is caused; (4) absence of complications, or, if any, with only mild symptoms.

I have to thank Dr. Beatty, physician to out-patients, for permission to publish these notes.

#### SUMMARY.

1. Drugs still hold their place in the treatment of whooping-cough. Of these belladonna seems to be the most useful.

2. Ether will check the disease completely in 25 per cent., fail completely in 25 per cent., and be followed by considerable improvement in 50 per cent.

3. Ether neither causes nor prevents complicating bronchitis; bronchitis already present is not a contraindication to its use.

4. The method of administration seems to be of no importance provided the dose is large enough.

## HAEMOGLOBINURIA FOLLOWING MALARIAL TREATMENT OF QUATERNARY SYPHILIS.

BY

G. DE M. RUDOLF, M.R.C.S., L.R.C.P., D.P.H.,  
ASSISTANT MEDICAL OFFICER, CLAYBURY MENTAL HOSPITAL.

SCHILLING and Jossman<sup>1</sup> have reported an instance in which haemoglobinuria occurred following malarial treatment with *Plasmodium vivax*. The temperature rose seven days after it had returned to normal; quinine (8 grains) was given, and almost immediately red, followed by black, urine was passed. The following day the urine was clear, but the patient was jaundiced. The temperature then fell gradually to normal during a period of about ten days. The authors were not able definitely to exclude paroxysmal haemoglobinuria, but believed that the case was one of blackwater fever. The following case is described as another example of haemoglobinuria following malarial treatment.

A man, aged 56, was given a subcutaneous injection of defibrinated blood infected with *P. vivax* on October 25th, 1923. Twelve days later febrile paroxysms occurred and the patient was allowed to undergo nine. The last rigor took place on November 22nd. A course of quinine bisulphate was commenced the following day. Two doses of 10 grains were given on each of the first three days and one dose of the same quantity on each of the following four days, making a total of 200 grains. In addition, the following course of neokarsivan was given: one dose of 0.3 gram, one of 0.45 gram, and four of 0.6 gram. The last injection was given on December 30th, 1923. The temperature was recorded every four hours for fifty-eight days after the cessation of the malarial paroxysms. On only seven days was it above normal; the highest temperature recorded (100.4° F.) followed an injection of neokarsivan. The temperature was then observed twice daily for twenty-eight days and no record above normal was noted. On the twenty-ninth day (February 18th, 1924), eighty-eight days after the last malarial paroxysm and seventy-one days after the last dose of quinine, the morning temperature was 98.8° F.; it was then recorded every hour. At 2 p.m. it had risen to 101.8° F., and at 3 p.m. to 103.6° F.; it then began to drop in a staircase manner, reaching 99° F. at 2 a.m. on February 19th, and normal at 10 a.m.

on that date. A rise to 99° F. occurred at 2 p.m. on the same day, but thereafter the temperature was normal or subnormal, the records being made every four hours for twenty-one days, and then twice a day for forty-seven days.

On the morning of February 18th, the day upon which the highest fever occurred, the patient was cyanosed and complained of feeling cold, but no definite rigor occurred. At 3 p.m. profuse perspiration appeared. The pulse rose to 100, and the respirations to 20. On this day dark, very aclear black, urine was passed; the urine passed on the following day was red, and the colour gradually became normal. Red cells were present in the urine on February 22nd. There was bacilluria on this date, but no tubercle bacilli were found. There was no vomiting, hiccup, or jaundice, but abdominal pain was marked.

A blood film taken on February 18th showed a large number of anæmic or pale red cells but no shadow cells. Spherocytes were never observed, nor was punctate basophilia or polychromasia detected in daily films from February 18th to 26th. Malarial parasites were not found.

The attack from which this patient suffered might have been due to blackwater fever or to paroxysmal haemoglobinuria. Both diseases can be brought on by cold. The daily minimum temperatures of the outside air showed a marked fall shortly before the onset of the attack. From the fifteenth to the sixth day before the attack the minimum temperature averaged 35.6° F., the lowest record being 31° F., and the highest 37° F. From the fifth to the day previous to the attack the minimum temperature averaged 22.6° F., the lowest being 19° F., and the highest 26° F. There was a pronounced fall of the indoor temperature on the night of February 16th-17th, the temperature of the ward in which the patient slept being 48° F. at midnight and at 2 a.m. on February 17th. The ward temperatures are recorded at 2 a.m., 7 a.m., noon, 7 p.m., and midnight, and 48° F. was the lowest temperature that occurred during the days immediately previous to the attack, 52° F. being the next lowest. The fall of the temperature to 48° F. was very sudden, there being a drop of eleven degrees in five hours. The rise after was gradual. The low temperature occurred about thirty hours before the onset of the attack of haemoglobinuria.

The fact that no quinine had been given for several weeks before the onset of the haemoglobinuria is of no assistance in diagnosis, for, although large numbers of attacks of blackwater fever are precipitated by this drug, many are not. Thomson<sup>2</sup> describes cases which had no quinine for several months before the onset of blackwater fever.

Turning now to the facts in favour of the diagnosis of blackwater fever, the number of attacks which occurred is important. If the patient suffered from paroxysmal haemoglobinuria it was possible that several attacks might occur over a prolonged period. The attack was, however, the only one during a total observation period of 679 days in Claybury and West Park Mental Hospitals. The patient was under observation for 317 days before the attack.

The presence of red cells is against the diagnosis of paroxysmal haemoglobinuria but not of blackwater fever. J. G. Thomson<sup>2</sup> has reported its occurrence in ten cases, and states that other writers have also observed it.

By the courtesy of Dr. N. Roberts, medical superintendent of West Park Mental Hospital, I have been enabled to perform the Eason-Donath-Landsteiner test for the autolysis of paroxysmal haemoglobinuria in the blood of this patient. In this disease haemolysis of the red cells occurs if a mixture of red cells and serum is cooled to 0° C. for five minutes and then placed at 37° C. for one hour. In this case haemolysis did not take place. This is against the diagnosis of paroxysmal haemoglobinuria, although it should be added that the test was not performed until March 4th, 1925.

The following facts suggest the diagnosis of paroxysmal haemoglobinuria. Jaundice is a very prominent symptom of blackwater fever, but it was absent in this case. J. G. Thomson<sup>3</sup> believes, from the study of the disease in Rhodesia and from the literature, that blackwater fever is due to a previous infection with *P. falciparum*. He states, however, that the disease may occur in persons after a relapse of benign tertian malaria, but he believes that in those cases there has been a previous infection with *P. falciparum*. This species is exterminated by quinine, and *P. vivax* causes the relapse. In the patient whose case is here recorded there was no history of previous malaria or

blackwater fever. The blood inoculated could not have carried a double infection of *P. vivax* and *P. falciparum*, for the strain had been passed through four persons before the case under review was inoculated. Since then sixty-eight inoculations have been performed with the same strain of parasite at Claybury Mental Hospital, and it has been used by other mental hospitals. Colonel S. P. James has also used the strain for mosquito inoculations. No malignant parasites have been found. The strain must therefore be a pure strain of *P. vivax*.

Yamakami<sup>3</sup> has found that about 25 per cent. of tertiary and congenital syphilites have the cold haemolysin in their blood. It is therefore probable that it might be present in a case of quaternary syphilis. Although the Eason-Donath-Landsteiner test was negative, it must be remembered that the test was performed a long time after the attack of haemoglobinuria.

The diagnosis of this case is therefore difficult, but on consideration of the detailed report of J. G. Thomson on blackwater fever it would appear that it is probably a case of paroxysmal haemoglobinuria.

In conclusion, I wish to thank Dr. J. S. Harris of West Park Mental Hospital for his assistance. For permission to publish records from Claybury Mental Hospital my thanks are due to Dr. G. F. Barham, medical superintendent.

## X RAYS IN THE DIAGNOSIS OF ORGANIC DISEASES OF THE COLON.\*

BY

ARTHUR F. HURST, M.D., F.R.C.P.,  
PHYSICIAN TO GUY'S HOSPITAL.

In estimating the value of radiology in the diagnosis of organic diseases of the colon, it is necessary to compare it with the other available methods of confirming, or otherwise, suspicions aroused by a consideration of the patient's history. Apart from the ordinary physical examination of the abdomen and digital examination of the rectum, the only direct means of investigating intestinal diseases are the x rays, investigation of the stools, and sigmoidoscopy.

For the purpose of this communication my colleague, Dr. J. F. Venables, has analysed all the cases of the kind which have come under our observation at New Lodge Clinic during the last four years. In each an x-ray examination has been carried out by Dr. P. J. Briggs, the stools have been investigated by Dr. J. H. Ryffel and Dr. J. F. Venables, and I have inspected the rectum and pelvic colon with the aid of the sigmoidoscope. The relative value of these different methods can thus be estimated, but it is at once clear that all are valuable and should be systematically used, as it is generally impossible to tell beforehand which will give the most important information in a given case, whilst in many the final diagnosis is only reached by a consideration of the symptoms and the results of the physical examination in the light of the information obtained—whether of a positive or negative character—with the x rays, the investigation of the stools, and sigmoidoscopy.

The series of cases includes 13 of carcinoma of the colon, excluding growths of the rectum which could be felt on digital examination, 5 localized adhesions of the colon, 5 cases of diverticulitis, 3 strictures following ulcerative colitis, 1 case of tuberculosis of the caecum, and 1 of tuberculosis of the last three inches of the ileum.

### 1. The X Rays.

(a) An x-ray examination after an opaque meal never reveals an obstruction of the colon which cannot be recognized with an opaque enema, but it is useful in the diagnosis of obstruction of the small intestines, especially near the end

of the ileum. In only 2 out of 12 cases of cancer of the colon was anything abnormal seen after an opaque meal.

(b) As I first demonstrated in April, 1908, an opaque enema shows the presence of obstruction at a comparatively early stage, often long before localizing symptoms develop. But a negative result does not exclude a growth of the colon; in 1 of the 9 cases in which an opaque enema was given and in 3 earlier cases a growth was found, though an opaque enema had failed to show the slightest abnormality.

An opaque enema is the only certain clinical means of recognizing diverticula of the colon. This is of great importance, as it may be impossible, even during an exploratory operation, to distinguish between a growth and an inflammatory mass secondary to diverticulitis. In one case in which we had found that symptoms of obstruction were due to diverticulitis, a recurrence of symptoms two years after the mass had been removed was shown by an opaque enema to be due to carcinoma developing in connexion with a diverticulum of the iliac colon, which had apparently escaped notice at the original operation.

Until recently I believed that ulcerative colitis never led to stricture on healing. I have, however, now seen 4 cases out of a series of 17, in which delayed recovery was due to narrowing of the colon, which was discovered with the x rays; in two of these the whole pelvic colon was shortened and narrowed, but complete recovery ultimately occurred without surgery. In the third case a long stricture was found in the transverse colon and a short one in the descending colon, and in the fourth a long stricture of the transverse colon and a kink of the pelvic colon; in neither were any symptoms pointing to obstruction present, but the x rays showed the necessity of short-circuiting operations, without which recovery would have been impossible. Delayed recovery in cases of ulcerative colitis, whether an appendicostomy has been performed or not, is thus an additional indication for x-ray examination.

### 2. The Stools.

Microscopical examination may show the presence of blood corpuscles and pus in stools which look normal to the naked eye. Much more frequently blood can only be recognized by chemical means and by the discovery of haematoporphyrin or acid haematin with the spectroscope. In 4 out of 12 cases of growth of the colon the blood was obvious; in all of the others occult blood was found in every stool. For some unknown reason it appears to be present with equal constancy when obstruction is caused by adhesions; thus obvious blood was present in 1 and occult blood in the remaining 4 of our cases of this kind; occult blood was also found in the cases of ileal and caecal tuberculosis. In 3 cases suspicious symptoms and the presence of occult blood induced us to advise operation, though the x rays had shown nothing abnormal; in 2 of these the symptoms were referred to the stomach and achlorhydria was present, and we diagnosed carcinoma of the stomach, so that an opaque enema, which might have led to a correct diagnosis before operation, was not given.

### 3. The Sigmoidoscope.

The sigmoidoscope is so invaluable in diagnosis that every practitioner and physician should learn to use it himself in cases of supposed colitis or unexplained disturbance in the functions of the bowels. With its aid a growth of the upper part of the rectum or lower part of the pelvic colon can be recognized before it can be felt—often before a barium enema shows any definite abnormality. By means of the sigmoidoscope I have twice been able to diagnose early malignant degeneration of a polypus before the wall of the bowel itself had become involved.

I hope that one result of this discussion may be to induce surgeons to avail themselves more frequently of the assistance given by a thorough investigation before embarking on an exploratory laparotomy. I have had the disappointment of learning that a patient, in whom we had diagnosed a growth of the splenic flexure, had had his appendix removed by a distinguished surgeon, whom he consulted without telling his own doctor, to whom we had sent our report; eighteen months later he was operated upon a second time for acute obstruction caused by an inoperable growth of the splenic flexure.

## PARKINSONISM TOGETHER WITH THE "APACHE TYPE" IN ENCEPHALITIS LETHARGICA.

BY

ALLEN HANCOCK, M.C., M.R.C.S., D.P.M.

Among the many late manifestations of encephalitis lethargica those met with in children and young adults are most striking and varied, and victims of this disease are found attending the out-patient department of most hospitals in increasing numbers. Whether such late manifestations are sequelae of the disease is doubtful; it seems more probable that they are rather the effects of a still active virus living in the nervous system, like that of syphilis—a view held by Netter, Mott, Wimmer, and others. A classification by Hall has put such juvenile cases under one of the following classes: (1) idiot type; (2) Parkinsonism; (3) apache type; (4) naughty child type. Of these Nos. 2 and 4 are especially common, and there are many of type 4 which nearly approach the true apache type, although not really bad enough in their moral defect. Such cases, however, cause great anxiety in their homes, and institutional care is usually called for. It is agreed by observers in this country, and on the Continent, that a combination of the apache type with Parkinsonism is of rare occurrence, and it is for this reason that it is felt that the following case, in which certification was necessary, may be of interest.

A labourer, aged 19, had a history of "influenza" in November, 1922, was "ill in bed for ten weeks"; "would sleep all day," and "has been sleepy ever since." After this illness he showed great moral deterioration. His report from school was an excellent one, and in it he was described as "diligent, attentive, regular, punctual, and respectful." After leaving school he was described as "of steady habits, hard-working, and a pleasant lad." In June, 1924—that is, nineteen months after his acute attack—he began to change in his attitude towards his relatives, who say that he "became had-natured, excitable, punched and kicked his mother and his small sister, threw knives about." In October, 1924, he was admitted to a mental hospital, his certificate stating that he had been charged at a police court with making a murderous attack on his mother. Inquiry showed that this was the third time he had been before the court on a similar charge. On the first occasion he was "remanded for medical examination"; on the second he was given "fourteen days' hard labour"; while on the third he was again remanded and sent to hospital, where he was certified.

On admission he was dull, retarded, sullen, and suspicious, and fabricated freely when his past was discussed. He was irritable in manner and abrupt in speech, and usually answered questions shortly and in an explosive manner. He was well nourished, pale of face, and had a greasy skin. His face was fixed and expressionless, his head bent forward towards the ground. Heart, lungs, and kidneys appeared normal. The knee-jerks were brisk, equal; plantars, flexor response; abdominal reflexes, present and equal. Pupils: react to light and accommodation, equal, regular outline, and not eccentric; no diplopia; movements of eyes complete. Ophthalmoscopic examination revealed no abnormal findings.

His gait was slow and stiff, and, when walking, he showed an absence of the normal swing of the left arm, which was held rigidly at the side. Myoclonic movements of the right shoulder were present, as were rapid blinking of both eyes. When agitated he showed frequent and regular sucking of the teeth, quite different from that observed in certain people when "on the defensive." His mother states that all these movements were not present prior to his illness. No abnormal sensory changes were detected. As is generally found in this disease, examination of the cerebro-spinal fluid showed no marked changes. It was clear; there was slight increase of pressure; Pandy's test was negative; protein not above 40 per cent.; the Wassermann test was negative; there was no excess of cells; Lange's test 0001110000; sugar 0.05 per cent.; chlorides 0.71 per cent.

Since admission he has shown some improvement at times, but remains bradyphrenic, rather slow and explosive in speech, and markedly bradykinetic. The Parkinsonian facies persists, but he has shown no violent tendencies and his behaviour has been satisfactory, although he has always been irritable and abrupt when addressed or examined.

The history of this case goes to show that this distressing disease is one that may raise difficult questions from a medico-legal point of view.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## HYDATIDIFORM MOLE.

HYDATIDIFORM mole is sufficiently uncommon to make the following case appear worthy of record.

The patient, aged 22, was admitted to a nursing home on October 26th, 1924; she gave a history of first pregnancy dating from about the middle of June. She had been losing blood for rather more than two weeks, and had been kept in bed under medical supervision, the case apparently being one of threatened miscarriage. On admission, after an uncomfortable journey of about forty miles by train and car, the pulse was 80 and the temperature 97.6° F. There was a slight brownish discharge not accompanied by pain. The uterus was enlarged to an extent corresponding with the history. The cervix, which was high up and quite soft, was only slightly dilated. The ovaries appeared normal. On October 28th an anaesthetic was administered and the cervix dilated. Pituitrin and quinine were given and the uterus massaged, but expulsion did not result. On October 30th the cervix was further dilated under an anaesthetic and the uterus carefully emptied of its contents—a vesicular mole. The patient made an uninterrupted recovery.

With regard to the frequency of this complication of gestation the figures of different observers vary from 5 in 4,000 pregnancies (=1 in 800) given by Engel, to 1 in 20,000 recorded by Madame Boivin. At the Rotunda Hospital, Dublin, in a series of 46,700 pregnancies the condition was found 22 times (=1 in 2,122.72); Fairbairn considers the average incidence to be 1 in 5,000. The condition is found most often in multiparous women towards the close of the child-bearing period.

NORMAN WILSON, M.D., B.Ch. Cantab.

Port Elizabeth, S. Africa.

## CONGENITAL FAMILIAL JAUNDICE:

The note by Dr. T. R. Thomson on congenital familial jaundice, in the *JOURNAL* of January 10th (p. 72), prompts me to record a similar family history from my own practice.

The father and mother both belong to families of two only. Neither knows of any family tendency to jaundice of the newborn, haemolytic jaundice, or haemophilia. Their ages are now 38 and 34 respectively. The history of their children is as follows:

1. Girl, born August, 1911. No jaundice; healthy.
2. Boy, born April, 1913. No jaundice; healthy.
3. Girl, born March, 1916. No jaundice; healthy.
4. Boy, born March, 1920. Jaundice from second day. Haemorrhages (of blood that did not clot) from umbilicus and bowels, beginning on eighth day. Died on tenth day.
5. Girl, born June, 1921. Jaundice from birth. Similar haemorrhages, beginning on eighth day. Died on tenth day.
6. Girl, born June, 1922. Slight jaundice for a few days. Survived; healthy. For four months prior to the birth of this child I got the mother to take calcium (syrup. calcii lactophos. 3ss daily).
7. Girl, born December, 1924. Jaundice from second day. Haemorrhages from axilla and bowel beginning on eighth day. Subcutaneous ecchymoses over the whole body. Died on the fourteenth day.

The last baby was given 1 grain of calcium chlorido every three hours from the second day, and an injection of 2 c.cm. of haemoplastin (P. D. and Co.) on the thirteenth day. The latter had not a fair trial. I had to get it from London after trying Glasgow unsuccessfully, and so lost a few days after making up my mind to use it. The mother had no ante-natal treatment, for a double reason. Owing to a housing difficulty and the possibility of having to leave the district, she did not engage me till five or six weeks before her confinement was due. I had—and still have—doubt as to whether the fact that the sixth child survived was really due to the prolonged treatment of the mother with calcium, and for the few weeks remaining it did not seem worth while to commence it again.

The age of the mother makes it probable that there will yet be opportunity of testing the effect of the calcium treatment. I have advised her that if she becomes pregnant again she should take it throughout the whole period of gestation.

Sanguhar, Dumfriesshire.

### MELAENA NEONATORUM TREATED BY INJECTION OF PATERNAL BLOOD: RECOVERY.

THE reports which have appeared recently in the *BRITISH MEDICAL JOURNAL* of the successful treatment of melaena neonatorum by injection of paternal blood made me think it worth while to record the following case.

On March 27th a multipara was delivered of an apparently healthy female child after a normal labour. I was called in on March 28th, at 1.45 p.m., to see the baby, who had been losing blood by the rectum almost continuously since 3 a.m. The child was blanched and cold. There had been no vomiting of blood. I withdrew 10 c.cm. of the father's blood and injected it deeply into the gluteal region of the child. While making the injection I noticed the free discharge of dark blood from the bowel, due to the child's straining because of the prick of the needle. Next morning there had been no more haemorrhage, and no further injection was necessary—a point to be noted, as one case reported required as much as 40 c.cm. of paternal blood.

The child's weight at birth was 8 lb. 4 oz. On March 31st it weighed 7 lb. The weight on April 19th was 8 lb., and the child is doing well.

There is nothing to note in the family history; there are seven other children, all healthy. The mother, however, tells me that prior to and during her pregnancy she had been living on a staple diet of bread, tea, and margarine, because of the unemployment of her husband.

JANEET C. MORRISON, M.B., Ch.B. Edin.

Campbelltown, Argyll.

### MITRAL STENOSIS IN PREGNANCY: CAESAREAN SECTION.

Dr. GUY BELLINGHAM SMITH's article, "The Ante-natal Clinic" (*JOURNAL*, March 7th, p. 440), induces me to publish a case of mitral stenosis in a pregnant woman on whom I performed Caesarean section some three years ago.

I attended the patient as a child for acute rheumatism, and during her teens I frequently gave her digitalis on account of attacks of auricular fibrillation. She married in the early twenties and became pregnant. During her pregnancy she frequently required digitalization for attacks of auricular fibrillation with orthopnoea. I had a consultation with a colleague, Dr. Frank Hiehens, and we decided that the best treatment, for both mother and child, was Caesarean section at term. We agreed that, if pregnancy went to term, a prolonged etherization with more or less accouchement forcé would be more dangerous than the short etherization necessary for a rapid Caesarean section.

Neither mother nor child caused any subsequent anxiety, and both are alive and well to-day. This method was adopted only after seeing many painful cases of decompensation (cardiac) in pregnancy and labour.

Camborne, Cornwall.

JOHN H. TONKING, M.B. Lond.

### RETROPHARYNGEAL ABSCESS: SECONDARY HAEMORRHAGE:

#### LIGATION OF COMMON CAROTID: RECOVERY.

A MALE, aged 24, was admitted into the hospital with a history of dysphagia for fourteen days and fever. A tender mass was felt on the left side of the neck, which bulged visibly. The temperature was 103° F. and the pulse 115. Chloroform was administered, and, as the incision was being made, he suddenly ceased breathing; judging from his colour he was suffering from respiratory embarrassment. Meanwhile he had regained consciousness and his respiratory distress was such that a high tracheotomy was instantly performed. This gave him immediate relief; the anaesthesia was resumed and the abscess evacuated. A drainage tube was inserted but replaced next day by gauze drainage. No pus was formed after the fourth day, and the temperature and pulse fell to normal. All went well till the seventh day, when blood was found pouring through the dressing. A thorough search was made for the bleeding vessel without success. As the bleeding continued the left common carotid artery was ligated. In a week he was sufficiently well to return home.

## Reports of Societies.

### RADIATION THERAPY.

THE discussion on radiation therapy in the Section of Electro-Therapeutics and Radiology of the Royal Society of Medicine was resumed on May 15th, Dr. STANLEY MEVILL presiding. The opening of the discussion on March 20th was entirely occupied by the introductory papers of Dr. Gilbert Scott and Dr. J. H. Douglas Webster (see *BRITISH MEDICAL JOURNAL*, March 28th, pp. 596 and 601), who on this second occasion briefly recapitulated their points.

Dr. N. S. FINZI said that x-ray treatment was in a state of some uncertainty, but until recently he was not aware that there was any doubt as to the natural history of new growths. Dr. Gilbert Scott had expressed the view that all new growths were general in origin, with local manifestations. He had heard only one other radiologist express that view, and he had imagined that nobody took him seriously. All surgeons and the majority of radiologists would certainly be of opinion that neoplasms were originally local and only subsequently became generalized. He wished that Dr. Scott would tell those present whether his general treatment of a case of carcinoma had ever proved successful in the sense that the patient had lived two, three, or more years afterwards. All radiologists were able to point to cases which had remained well for five or ten years. All his (the speaker's) own cases which had remained well for a long period after x-ray treatment were cases of sarcoma; he had also cases of carcinoma which had remained well for a long period, but these had been treated by radium or by a mixed method (radium and x rays). It looked, therefore, as if the softer radiations would answer the purpose in sarcomas, but that in carcinomas, and especially in epitheliomas, a harder radiation was necessary. Lately in Paris he had seen a series of cases, proved by sections to be cases of epithelioma, in which, following radiation treatment, the growth had disappeared for from two to five years. These had been treated at the Radium Institute in Paris by the use of filtered radium and filtered x rays. The filtration in the case of the x rays was on a scale never attempted in this country—2 mm. copper—and a current of 200 kilovolts was used. In the speaker's own experience, local treatment, provided an area of sufficiently wide extent were taken, was successful in a certain number of cases—not in all, because the methods had not yet been absolutely mastered. The local treatment of metastases was also successful. Lymphosarcoma in particular was one of the growths which responded readily to any type of radiation; the less penetrating radiations were often sufficiently effective in this condition. But the hard or more penetrating radiations had given the radiologist the power of getting effective radiant action at the seat of the disease without damaging the intermediate tissues to any extent, although, of course, it was always possible that those tissues might be damaged by wrong technique or careless work. It was also necessary to remember that with these very penetrating radiations there was a late effect, appearing, in some cases, three or four months after treatment, even though nothing had been done in the interval, and this fact had to be brought into the reckoning when it was proposed to use other treatment later on. With intensive doses radiation sickness was likely to occur; the upper abdomen could not be irradiated without getting radiation sickness. But, apart from that area, he found radiation sickness occurring but seldom now in his own practice; he had avoided it by thorough ventilation of the room, and by getting rid of corona discharges in the neighbourhood of the tube, and of ozone and nitrous oxide as far as possible. In cases likely to have sickness the administration of chloroform was helpful. Another precaution was to refrain from giving too much radiation at one time. He had spread treatments over several days, and even weeks, and yet had got an intensive dose. His tendency was still to push the radiation higher and higher. He treated certain cases with rays of low penetration, but the results he obtained with the higher penetrations seemed to him infinitely better.

Professor SIDNEY RUSS said that the differentiation which Dr. Gilbert Scott had made between direct and indirect action needed to be borne in mind. It was not difficult to get proof of indirect action. He wondered whether the rather large doses which it was customary to give in deep x-ray therapy were really necessary. The dose which was necessary to prevent the growth of the cell was perhaps not the most useful criterion for clinicians to take; it was also necessary to take into account the resistance which the individual might put up to the growth. Radiologists should endeavour to settle amongst themselves, not the maximum dose which they dare apply, but the minimum dose consistent with beneficial effect. He could not help feeling that the use of the more penetrating rays had gone ahead without sufficient experimental warrant. The use of these penetrating rays required just as much experiment beforehand as x-ray treatment on what might be called moderate lines had received.

Dr. ROBERT KNOX spoke of the nature of tissue response to radiation. He said that the chief point to grasp at the outset was that the problem was not a strictly physical one. It was useless to pursue a chase after higher and higher voltage as a solution of the problem. The apparatus which radiologists now had at command was sufficiently powerful to give radiations of such quality and quantity as would act upon and kill any tissue in the human body. Radium, which gave the most penetrating radiations at present known, had been used in sufficient quantities to test that point. But the fundamental considerations in tissue changes were the type of cells and their responses, the phase of activity at the time of exposure, and the fact that in treatment of disease the response and action of the normal tissues was of vital importance. The biological unit, which at the same time was a unit of structure and a unit of function, must dominate the consideration. After describing some cases, Dr. Knox expressed the view that the radiation technique of the future would change very considerably, and that some development on the lines suggested by Dr. Scott in his paper would follow. He did not suppose that direct and local treatment would ever be discarded, but he did look to a much wider distribution of the area of treatment in a case of carcinoma. He also urged the value of the information derived from blood counts. If observations were made carefully enough, information could be obtained from the blood which was available in no other way. All cases submitted to any kind of radiation treatment should have very careful blood counts made. He also recounted a case which bore out the point that it was possible to sensitize a patient to a course of radiations to such an extent that if a dose of another quality, representing a drop in the penetration value, were given, a very different response was immediately manifested.

Dr. W. MITCHELL rather quarrelled with the term "prophylactic treatment," because, strictly speaking, none of the cases exhibited to the Section were cases of true prophylaxis. He described one case of a woman sent to him two years ago with carcinoma affecting both mammary regions. In one region there had been operative interference, and the results of radiation treatment following operation were so encouraging on that side that he asked the surgeon to remove the other breast. This woman was comparatively well to-day, although not cured; she was given an occasional dose still, with 0.5 mm. zinc filter, and she had no internal recurrences. In sarcoma cases he had had some excellent results, including sarcoma of the ericoid process with secondaries in the neck. Under deep radiation treatment, using 0.5 mm. filter, the condition cleared up in a remarkable way.

Dr. F. HERNIMAN-JOHNSON found himself in general agreement with Dr. Scott. He wanted to consider the duty of the radiologist, not in regard to those cases in which the surgeon had admitted failure, but those in which the surgeon thought the operation most favourable, and, indeed, believed that by surgery alone the disease had been eradicated. Here was a patient who, after operation alone, might expect to have good health for at least two or three years, and might live for an indefinite number of years. Anything that the radiologist did should be with the object of improving the health of that patient from the

very start. The radiologist might be justified in taking various risks when he was treating a case which the surgeon had abandoned in despair, but when the disease appeared to have cleared up after operation, and he did not know that any vestige of disease remained, he must be very careful to do nothing which was likely to injure. His own advice would be that the same course should be followed as was customary in the general treatment of tuberculous patients—that is to say, everything possible should be done to raise the patient's resistance. In breast cases there was a certain area under suspicion—namely, the breast itself, the axilla, and the supraclavicular region. That seemed to be "fair game" for fairly wide x-ray treatment. He would suspend the tube with a wide open diaphragm two feet above the patient, shielding the face. The dose should be small, the time short—ten to fifteen minutes—and a 3 mm. filter should be used. He thought it would be found that after such treatment the patient would declare from the start that she felt better and stronger. But an attempt ought to be made to do something more than that. Whether what might be called the x-ray bath or generalized x-ray treatment, as advocated by Dr. Scott, was the best for that purpose was a little open to question. But there was available in sunlight and ultra-violet rays a method of raising the patient's general resistance, and the speaker advocated a plan whereby the treatment of the local area widely by x rays was alternated with a course of general sunlight treatment as in tuberculosis.

Dr. J. E. A. LYNHAM said that the improvement following a change in voltage to which Dr. Knox had referred was of great interest. A similar plan had been followed in the treatment of a number of cases of carcinoma which had come under his observation, with good results. Recently one of the surgeons at the Cancer Hospital had been going through the statistics relating to carcinoma of the uterus, and had found that the cases which had shown the best results were those in which radium had been used, followed by x rays of penetrating quality, the exposures lasting half an hour twice a week and then spacing out to quarter-hour exposures once in ten days; after an interval in which no exposures were given this spaced-out treatment was resumed for a further period. With regard to generalized radiation, he thought it should be borne in mind that the size of the aperture was of very great importance. If one was going to give radiation on the principle put forward by Dr. Scott the time of dosage should be extremely limited. Recently he had been irradiating inert chemical solutions for the research department. In the first series of radiations the Coolidge tube was kept in the usual lined box, and a small aperture was used; very little change was seen in the solution even when it was placed more or less directly under the tube. Then it was suggested that similar solutions should be irradiated without the tube box so that the whole fan or cone of rays might bear upon the solution, and in that case the changes were profound, although the time of irradiation was the same. If such a change could take place in solutions so irradiated, it seemed that the changes induced in the human body by rays from a relatively wide aperture must be very great indeed.

Dr. DOUGLAS WEBSTER, in replying on the discussion, agreed with Dr. Lynham that if the x-ray "bath" over a very large area was given it must be given only for a limited time. He thought that the best results obtained by general treatment with x rays were in leukaemia and Hodgkin's disease, but there the conditions were quite different from those obtaining in breast cancer. He failed to see that Dr. Scott had established his case. Professor Russ had stated that a generalized small dose improved the resistance of animals to the implantation of tumours. But the fact remained that generalized small doses did not, so far as the speaker was aware, have any effect upon spontaneous tumours. He suggested that it would assist the position if surgeons would record their breast cases in certain definite groups, according to the condition obtaining at the time of operation. On the general question in debate he was in agreement with Dr. Scott that at present medium-voltage therapy was best for prophylaxis, but he thought Dr. Scott's dual method deficient in several respects, and that in formulating it the pathology of breast cancer had not been fully considered. If one accepted the

view that cancer spread along the lymphatics one must work ahead of clinical signs of the disease, and try to stop it from going any further. The supraclavicular triangle was one great danger zone in breast cancer, and he thought this liable to be neglected under Dr. Scott's method.

Dr. GILBERT SCOTT, also in reply, claimed that by his general or open method he was getting results in cases where he had had no results before—results, for instance, in secondary deposits in the spine. The value of varying the dosage had been mentioned. He wanted to have at his command radiations from the lowest to the highest in quality, and to be able to use filters of different types. On the question of whether a malignant disease was general or local, the practical point for radiologists was that every case, by the time it reached their department, was a general disease. It never reached the radiological department as a localized manifestation.

### X-RAY DIAGNOSIS OF DISEASES OF THE COLON.

In the Subsection of Proctology of the Royal Society of Medicine on May 13th, Mr. F. SWINSON EDWARDS presiding, a discussion was held on the value of x rays in the diagnosis of diseases of the colon.

Dr. GILBERT SCOTT said that this subject was of equal importance to the surgeon and the radiologist. The radiology of the colon had not been developed to anything like the same extent as had the radiology of the stomach, and hence the full diagnostic value of the method had not been recognized. The value depended on correct technique and correct interpretation of what was seen. He regarded the opaque enema as being of as much value in colon cases as the test meal for stomach disorders. In the case of the colon, by the time an opaque meal had reached the lower gut it was so much broken up, and the illustration was so marked, that examination was tedious, and at the end one could not be certain whether or not an organic lesion was present. For colon cases, therefore, he had for some time past discarded the meal and substituted the opaque enema. The gut could be easily manipulated under the screen, and the examination was soon completed without discomfort to the patient. The patient should be carefully prepared, as the presence of faeces might lead to errors in diagnosis. With regard to the interpretation, there were two classes of error: (1) that the lesion might be passed undetected, (2) that inspection of the plate might lead to the diagnosis of a lesion which was not confirmed at operation. The pitfalls included faeces in the colon, air-bucks, pressure from without, spasms, and partially filled gut. Most difficulty was caused by small and atypical lesions. To differentiate between tubercle and new growth by the rays was, he considered, practically impossible. He related a number of cases to show the value of the enema method, and showed skiagrams by the epidiascopic.

Mr. HAMILTON DUNNISON said that he had long believed in this method as an aid to diagnosis, but his sanguine views of years ago had been somewhat modified by experience. To estimate the value of x-ray findings considerable experience of the pitfalls was necessary. The method should always be combined with abdominal palpation. During the last five years he had been his own radiologist for colon cases. If the surgeon was to derive the full benefit of this means of diagnosis he should either furnish the radiologist with a full history of the case, or, better still, meet him in consultation. Sometimes patients were sent to the radiological department without an ordinary clinical examination being made. This clinical examination should include the use of the sigmoidoscope. X-ray examination of the colon by the barium meal or enema was seldom the primo factor in diagnosis; histories often furnished information of the greatest diagnostic value. Flexures of the colon were particularly difficult points at which to locate a growth, as here the shadows overlapped.

Dr. BERTHA SHIRES was in agreement with Dr. Scott

as to technique, and also with his statement that no examination could be regarded as complete if only one method was used. In the majority of colon cases he felt that an opaque enema was of the greatest value, but there were many traps into which one might fall unless there was close co-operation between surgeon and radiologist. On giving a barium enema there was a filling defect in the pelvic colon in the early stages in 30 per cent. of the cases. The x rays often enabled spastic colon to be diagnosed when it could not be recognized by any other means. In one case a great deal of gas in the pelvic colon caused an irregular filling, and this irregularity, on a further filling, completely disappeared. In one case the skiagrams after an enema and the clinical findings also pointed to carcinoma, but abdominal section revealed nothing but slight spasm at the lower end of the descending colon.

Dr. ARTHUR F. HURST's communication is printed in full at page 965.

Dr. ULYSSES WILLIAMS agreed with Dr. Scott about the practical unimportance of the barium meal in these cases. It was quite valueless, he thought, in diseases of the colon, except to show position. The barium enema was useful. It was necessary to be very careful on finding an apparent stricture before determining that it was actually a stricture, for a stricture could readily be simulated. With regard to showing the appendix, it was quite useless to give the ordinary barium meal made with milk or arrowroot. The only satisfactory vehicle was buttermilk, which would fill the appendix in 70 or 80 per cent. of cases. The drawback was that the buttermilk was so very disagreeable that it was difficult to get patients to take it. He started on an investigation on 100 normal people with buttermilk, and after a first experience the volunteers were reduced to 12. His investigation, the results of which he showed in a diagram, proved that, on the basis of the findings in these 100 normal persons, the level of the hepatic flexure in 75 per cent. of cases was just at the crest of the ileum, two or three inches below the position given in the anatomy textbooks, and where the people who believed in coloproxy thought it ought to be. His results suggested that variation in the level of the colon alone, without anything else, was of no importance.

Mr. J. P. LOCKHART-MUMMERY said that the fact had to be borne in mind that a great improvement had taken place in the diagnosis of conditions of the colon during the last twelve years. Formerly tumours were diagnosed only when they were large and palpable, or when there was acute obstruction. Surgeons had recognized that unless some marked improvement on that state of affairs was forthcoming there were not likely to be satisfactory results in colon carcinoma. The real problem was to diagnose carcinoma when there was no obstruction and no palpable tumour. A big step had been taken in this direction. Of the various methods available in diagnosis he personally attached more significance to the sigmoidoscope than Dr. Hurst appeared to do. If a patient with growth in the colon were examined with the sigmoidoscope when he had not been prepared in any way, there would be found, in the majority of cases, slight traces of blood up in the sigmoid, and one might be pretty certain that one had to deal with a growth high up in the colon (it was taken for granted, of course, that such a condition as ulcerative colitis was excluded). He thought that x rays had helped most markedly in regard to the position of the growth, and that great improvements had still to take place in the diagnosis of position by x rays. The radiographic experts at first were rather too enthusiastic about their method, and they made much too elaborate diagnoses from the x-ray findings. A more reasonable view was now taken. He thought that negative x-ray evidence was useless. It was not possible to declare that there was a normal colon simply because the x rays showed nothing abnormal. X-ray evidence could only be taken as confirmatory evidence. One method of avoiding error in x-ray diagnosis of the colon was by repeated examinations. At least two or three examinations with the barium meal should be made. Perhaps the greatest value of x rays was found in diverticulitis; x rays furnished a method of distinguishing this from other conditions of the colon, and a proper x-ray examination would confirm or exclude diverticulitis.

\* For Dr. Scott's technique see BRITISH MEDICAL JOURNAL, January 24th, 1925, page 151 ("Radiological examination in organic diseases of the colon: the opaque enema method," by S. Gilbert Scott).

Dr. W. H. COLDWELL said that there were not many who doubted the value of x rays, but it was necessary to remind themselves persistently of the failures. One of the reasons why the x-ray examination had not yet been made more use of was because it had not been worked out fully. Surgeons and radiologists were both to blame for that—the surgeons for not supplying the material and the radiologists for not making more use of it. Most of the previous speakers had rather condemned the barium meal. Dr. Coldwell thought that there was a great deal to be said for the use of the meal in conjunction with the enema. He described a case which had rather caused him to doubt the efficiency of “wash-outs” previous to the administration of an enema. As illustrating how very careful one must be before coming to definite conclusions from the first x-ray appearances, he said that he had often seen apparent filling defects on the screen when the patient was lying on his back, but on turning the patient over into the prone position the defect was obliterated.

Dr. S. C. SHANKS spoke of two “silent areas,” one in the sigmoid, where the sigmoid loop might be superimposed upon another loop and so obscure symptoms, the other in the splenic flexure; the barium enema fell to the more dependent portions, and the portion of gut which looped over the ridge formed by the spinal column was not filled by the meal.

Mr. ASLETT BALDWIN related the case of a patient who complained of inconvenience in the left abdomen, with defaecation trouble. Examination with the sigmoidoscope did not reveal blood or mucus. An x-ray examination was made, and the report was that there was no filling defect or obstruction. The patient was put upon paraffin. Six weeks later, however, the patient said he felt certain there was something present. The speaker thought he could now feel a lump and distension of the large intestine. Operation disclosed a carcinoma in that position.

## Reviews.

### THE ANTIQUITY OF MAN.

REMEMBERING the special nature of its subject and the mass of detail only to be understood by minute attention to the text and careful study of the numerous drawings and diagrams and maps it contained, the first edition of *The Antiquity of Man* had a remarkable measure of success. It was published, inopportunistly as it might have seemed, in October, 1915, but it had to be reprinted in December, again in February, 1916, and for a third time in March, 1920. Sir ARTHUR KEITH had therefore every encouragement to prepare a second revised edition, and if revised then enlarged, for many new discoveries had been made in the ten years. The new edition,<sup>1</sup> though pagged consecutively, has been bound in two volumes, and is therefore easy to read in an armchair—the proper place for the general reader, among whom will be found many members of the medical profession who, though not anthropologists, will find their anatomical knowledge a great help to the understanding of one of the most fascinating stories in the world. Here and there it may be well to skip, but the actual finds are so graphically related, and the conclusions therefrom drawn with so much insidious art, that the book is not easy to put down.

The excellent summaries printed in our columns last week (p. 941) and this week (p. 980) of the course of Munro lectures Sir ARTHUR KEITH has been delivering to the University of Edinburgh give a very good preliminary idea of the material in the book. As in the first edition, the story is unfolded in reverse chronological order. The discoveries of fossil man in South Africa have affected many of the problems the solution of which was, ten years ago, being sought from a study of European specimens; and the descriptions of Boskop man (1913) and Rhodesian man (1921) naturally occupy a great deal of space, and are largely responsible for the increase in the number of pages in the book.

The dictionary maker may define anthropology as the “physiological and psychological science of man,” but the complete anthropologist must have knowledge of a good many collateral sciences. First and foremost, he must be well acquainted with anatomy, human and comparative, including odontology; with geography, physical, geological, and human; with geology; and with archaeology, including folklore. Sir ARTHUR KEITH does not fall short in any of these respects, and shows once again how competent he is to handle an immense mass of details and to make them plain, achieving his end, not only through a very clear and well written text, but by the liberal use of diagrams and drawings, which it must have been a very laborious task to produce.

As we read the book its main thesis is now, as in the previous edition, the great and, until recently, unsuspected antiquity of modern man. The geologist and astro-physicist will give all the time the anthropologist wants, but Sir ARTHUR KEITH is now prepared to reduce his demands. Here, however, we come to see more clearly that a great deal depends upon the definition of man. What is meant by man? Logically this ought to have been the first question. But great as may have been the faith of early writers in the doctrine of evolution, it was impossible to foresee the full significance of the need for such a definition until the recent discoveries had been made. Granted that the ancestors of man branched off at some period, remote even in the geological sense, from the main stock which was to yield not only man but the anthropoids; the question is, When in the upward course did the creature develop the qualities which entitle him to be called man? When, as the author says, we speak of the antiquity of man, “most of us have in mind not the date at which the human lineage separated from that of the great anthropoids, but the period at which the brain of man had reached a human level or standard.”

Another consideration to which in the new edition more importance is attached is the occurrence of “collateral evolution,” a phenomenon known to geologists as the “law of uniform evolution.” No one, the author tells us, has had better opportunities of studying this law than Dr. HENRY F. OSBORNE, and this is his statement of it:

“Some of the most universal laws as to the modes of evolution emerge from the comparative study of the horses, the proboscideans, and the rhinoceroses, from areas so widely separated geographically that there was no possibility of hybridizing or of mingling the strains. For example, during a period, estimated at no less than five hundred thousand years, the horses of France, Switzerland, and North America evolve in these widely separated regions in a closely similar manner and develop closely similar characteristics in approximately a similar length of time. The same is true of the widely separated lines of descendants from the mastodons, elephants, and rhinoceroses.”

This again has led to a shifting of opinion and a consequent change in the time table. The idea with which anthropology set out to investigate the genealogy of modern man was that the various types of primitive man succeeded each other in a single-stemmed ancestral tree running up something after the manner of a bamboo to flower in the chief races of modern man. It is now seen, or at any rate the progress of investigation has now made it highly probable, that the process of evolution should be compared with, say, the elm, and that of many branches some have lost their vitality and dropped off. This fate, it is thought, befell Neanderthal (Mousterian) man and also Rhodesian man. The process of extinction may have taken many thousand years, probably hundreds if not thousands of generations, for there is reason to think that for a very long period Neanderthal man dominated, if he did not overrun, Europe. The long struggle between the two types or varieties makes an appeal to the imagination. Mr. Kipling has touched the fringe of it. The victory must have gone to the better but not, it would seem, to the larger brain.

### A CLINICAL HANDBOOK ON DISEASES OF CHILDREN.

Dr. R. HUTCHISON's *Lectures on Diseases of Children* has now reached its fifth edition.<sup>2</sup> With successive revisions and additions it has become a larger volume, and now, indeed,

<sup>1</sup> *The Antiquity of Man*. By Sir ARTHUR KEITH, M.D., D.Sc., LL.D., F.R.S.E., F.R.S. In two volumes. New and enlarged edition, completely revised and rectified. London: Williams and Norgate, Ltd., 1925. (Med. Bro. Vol. I, pp. xxvii + 376, 133 figures; Vol. II, pp. xiv + 377, 266 figures. See the two volumes.)

<sup>2</sup> *Lectures on Diseases of Children*. By Robert HUTCHISON, M.D., F.R.C.P. Fifth edition, revised and enlarged. London: E. Arnold and Co. 1925. (Demy Bro. pp. xii + 459; 87 figures. 25s. net.)

gives a fairly complete presentation of the subject; but it retains its original character and presents the subject, not in the form of a systematic treatise, but as a set of classroom lectures. It was, indeed, as a course of lectures that the book came into being; and not only is its title genuine, but the text also bears unmistakable evidence of the language and atmosphere of the classroom. In the present edition six lectures have been added; among the subjects discussed in them are acute rheumatic carditis, convulsions in childhood, "the solitary child," and the diagnostic significance of abdominal pain in childhood. The book now consists of thirty-six lectures, and their subjects include all the important and common conditions of illness in children met with in practice. But the author never loses sight of his original aim of giving to students, already oppressed by a heavy curriculum of study, a clear, practical, and adequate account of the important diseases of early life. Indeed, the word "author" is a misnomer; for it is as a teacher, with his students gathered round him, that he appears in the book: emphasizing what is salient or significant, constructing a diagnosis, and specifying remedies. While he is always clear both in thought and language, and dogmatic also, as every good teacher should be, he is not afraid to say that here the matter is doubtful, or, again, that he does not know. This last is indeed one of the high and uncommon merits of a teacher that in drawing out the map of knowledge for his pupils he scrupulously traces the boundaries where knowledge ends and the unknown begins. When that is done by a teacher with undoubted claims to knowledge and experience, the student not only gets a surer grasp of ascertained facts, but his critical faculty is trained and he may also receive an impulse to himself explore and investigate the territory of the unknown.

These discourses of a teacher are beyond doubt adapted to the needs of students of the subject; but they will also appeal to the practitioner, for their material is drawn directly from the bedside, and points of special importance are illustrated by the citation of case-records and by photographs and diagrams.

Further, the book is of interest to those who, like the author, are engaged in teaching this subject. For it is an actual model of a course of teaching in diseases of children. That subject has only in recent years obtained a separate place in the medical curriculum; and it has not yet gained the status of an examination subject. Until this last step is taken the programme and scope of its teaching can hardly be standardized. But in the meantime Dr. Hutchison has furnished in his admirable book a syllabus of contents, and a plan of teaching, which will assist in the determination of how much of diseases of children should be taught to the student of medicine, and in what way the subject should be presented.

#### THE MICROSCOPY OF THE LIVING EYE.

ALTHOUGH the microscopy of the living eye has been practised in this country by a few ophthalmologists for some years, and although it has been the subject of a number of papers, some of which, including several by Mr. Harrison Butler and Mr. Basil Graves, were published in our columns during the last year, the only textbooks hitherto available have been in German, and Vogt's atlas, though excellent, is a large work written in a rather difficult style. We welcome, therefore, Konx's *Microscopie de l'Oeil vivant*,<sup>2</sup> written by a pupil of Vogt for the beginner, which is smaller, more simple, and (may we confess it?) less concerned with forbidding mathematics.

The book begins with three chapters of an introductory nature. In the first, the corneal microscope and slit-lamp are described, and the exposition of their principles certainly does not err in being too technical. In the second, the methods of examination are given in detail, and so clearly that the novice may understand. In the third, we consider the phenomena of the reflection of light from the ocular surfaces and media—a frequent source of error on which the author lays special stress. The remainder of the book deals seriatim with the various structures to which the

slit-lamp affords access; separate chapters are devoted to the conjunctiva, the cornea, the anterior chamber, the iris, the lens, and the vitreous: of special interest are the remarks on corneal pigmentation and thermal currents in the aqueous. Each section is arranged systematically under six heads: the special technique appropriate to the organ under consideration, the normal aspect, congenital abnormalities, senile characteristics, traumatic, and pathological lesions—an arrangement which has the advantage of simplicity and ease, but which, like all schemata, on occasion leads the author into difficulties. Throughout especial stress is rightly laid upon those physiological variations from normal which may be mistaken for pathological lesions, and upon the early departures from normal rather than on the appearances of advanced disease. The monograph ends with a very complete bibliography.

The author has maintained throughout a nice balance between enthusiasm and restraint, and points wherean as yet opinions differ are treated with commendable sanity. The method is still in its infancy, and the interpretation of the appearances seen is not always easy and is to a large extent a personal factor; Kohy will be found a careful and unprejudiced observer. The book is the best, in fact the only one of its kind, and to those who can read French, and have access to one of Gullstrand's instruments, will be found a safe and pleasant guide in a fascinating voyage of discovery.

#### A FRENCH SYSTEM OF MEDICINE.

THE twenty-two volumes of the French encyclopaedia entitled *Nouveau Traité de Médecine* are appearing at fairly regular intervals. The system is planned to cover the whole field of medical science, though practical medicine and pathology come in for most attention.

We have drawn attention to earlier volumes as they have appeared, and we now have to deal with three others that have appeared recently.<sup>4</sup> Volume XI is on the pathology of the respiratory system, and seven authors have contributed to it. It opens with an introductory essay on the symptoms of respiratory disease, and this is followed by essays on the pathology of the nose and larynx, diseases of the trachea and bronchi, asthma, bronchopneumonia, congestion, oedema, abscess, and gangrene of the lung, pneumonia, pulmonary embolism, emphysema, syphilis, fibrosis, pneumokoniosis, atelectasis, cancer, and hydatid cysts of the lung.

Volume XIV is devoted to the digestive system, and to it also seven authors have contributed. The subject of intestinal diseases is not handled very systematically, but each particular theme, about which an expert writes, is dealt with exhaustively. These are the successive sections of the book: intestinal pathology, gastro-intestinal diseases of infants, intestinal worms, ankylostomiasis, analysis of faeces, and pathology of the rectum and colon.

Volume XXII deals with diseases of muscles, bones, and joints. It contains eight chapters on the following subjects: diseases of muscles, acquired diseases of bones, congenital lesions of bones, rickets, osteomalacia, achondroplasia, infectious and toxic pseudo-rheumatism, and finally chronic rheumatism.

This series of well illustrated books has been published under the direction of Professors G. H. ROGER, F. WIDAL, and P. J. TEISSIER.

#### "BRAIN."

THE new number of *Brain*<sup>3</sup> (the first part of the forty-eighth volume) follows close on the heels of the last part of the forty-seventh volume. The first paper in the new number is on the lipoids in neuronic degeneration and in amaurotic family idiocy, by Dr. E. Weston Hurst. It comes from the pathological laboratory of the National Hospital for the Paralysed and Epileptic, and is the result

<sup>2</sup> *Microscopie de l'Oeil vivant*. Par F. Ed. Kohy, Bile. Paris: Masson et Cie. 1924. (Med. 8vo, pp 240; 43 figures. Fr. 25.)

<sup>4</sup> *Nouveau Traité de Médecine*. Publié sous la direction de MM. les Profs. G. H. Roger, F. Vidal, P. J. Teissier. Paris: Masson et Cie. Fascicule XI: Pathologie de l'Appareil respiratoire (Ror. 8vo, pp. 636; illustrated. Fr. 45). Fascicule XIV: Appareil Digestif (Fr. 578; 166 figures, 7 plates. Fr. 45). Fascicule XXII: Muscles, Os et Articulations (Fr. 550; 209 figures, 2 plates. Fr. 45).

<sup>3</sup> Published in London by Macmillan and Co., and in New York by the Macmillan Company. Yearly subscription in this country 21s., to be sent to Messrs. Macmillan, St. Martin's Street, London, W.C.2.

of work conducted during the tenure of the Walter Olyer's travelling studentship of the University of Birmingham. Dr. Hurst has investigated the fatty substances found in the nervous tissues in disease by a series of staining methods, and concludes that the duration of the disease is a main factor in determining the type of lipid present. He noted that, in the breakdown of myelin, phosphatides, cerebrosides, fatty acid, and neutral fat are found successively according to the duration of the degeneration. He then studied the lipoids in amaurotic idiocy, cerebro-macular degeneration, and in the senile nerve cell. He considers that the degeneration is essentially of the same nature in all these conditions, and that the differences that exist depend on the acuteness or chronicity of the process. The next paper, by Mr. Howard Florey, John Lucas Walker student, is founded on microscopical observations on the circulation of the blood in the cerebral cortex, made in the Physiological Laboratory, Oxford, and the Pathological Laboratory, Cambridge. By means of a Spencer dissecting microscope with illumination from a 100-candle power Pointolite lamp, direct observations with an average magnification of 50 diameters were made on the cerebral cortex in cats and rabbits; in other experiments the anterior surface of the medulla and the floor of the fourth ventricle were similarly observed. The cerebral arteries were found to react by contraction or dilatation to mechanical, thermal, electrical, and chemical stimuli, but no contraction was obtained by the local application of adrenaline, thus confirming the suspected absence of vaso-motor control of the cerebral vessels. The early stages of inflammation of the meninges were observed, and showed no essential difference from inflammation in other parts of the body.

In an interesting article on astereognosis Professor G. Campora of Geneva discusses the nature of this symptom in central and peripheral lesions of the nervous system. He finds that true astereognosis is invariably associated with deficiency of tactile discrimination as revealed by Weber's compass, and considers that such deficiency is the essential factor. Defect in the sense of position is also always present, but he believes that it is not an essential element, since this sense may be markedly defective without astereognosis occurring.

The many respiratory disturbances seen in the early, and especially the late, stages of epidemic encephalitis are classified by Dr. W. Aldren Turner and Dr. Macdonald Critchley into disorders of rate, disorders of rhythm, and respiratory ties. They put forward the view that a disturbance of cortical centres concerned in the control of respiration is a more probable explanation than the presence of lesions of respiratory centres in the medulla or basal ganglia.

Dr. W. Russell Brain contributes a clinical study of increased intracranial pressure in sixty cases of cerebral tumour, with special reference to the time of onset of the three principal symptoms—headache, vomiting, and papilloedema. Vomiting, he considers, is always a symptom of hydrocephalus, and is therefore earliest in tumours which cause obstruction of the aqueduct of Sylvius—that is, in most subtentorial tumours. In such tumours papilloedema is also the result of hydrocephalus, but is found to occur later than vomiting; in supratentorial tumours papilloedema is more likely to be due to a local rise of pressure without hydrocephalus, and therefore precedes vomiting.

### NOTES ON BOOKS.

A much felt want has recently been met by the Association of Infant Welfare and Maternity Centres, which has published a *Mothers' Cookery Book*.<sup>1</sup> It is a pamphlet of 48 pages with an index, informing mothers how to prepare simple, cheap, and tasty meals. Most cookery books present an embarrassing array of expensive recipes and are prone to consider that a milk pudding added to the daily menu sufficiently provides for the needs of growing children. This pamphlet gives recipes of dishes which can be enjoyed by the entire family

and consumed by the toddler with safety and advantage. The 150 recipes are grouped under the headings: soups, fish, meat dishes, vegetables and egg dishes, puddings, cakes, drinks, and each group is an explanatory note indicating the recipes suitable for children under 18 months and emphasizing the foods which contain vitamins. The simple recipes for cooking vegetables are especially good. The book is specially designed for the use of mothers attending welfare centres, but all mothers who take an interest in the most suitable diet for their children could not do better than expend fourpence on it. The Association of Infant Welfare and Maternity Centres has made an effort to translate the scientific findings of modern research in dietetics into language which can be understood and recipes which can be carried out by all. The association may be congratulated upon having achieved such a result.

The 1925 edition of the *Yearbook of the Universities of the Empire*<sup>2</sup> has been increased by some fifty pages; it presents the same arrangement which has made it so valuable a book of reference since its first publication in 1914. Numerous details about the universities of the world are set out so systematically and indexed so carefully that any point of practical importance can be ascertained without difficulty. In the 1924 edition the appendices devoted to universities outside the Empire included twenty-one different countries; to the 1925 edition eight new countries have been added—namely, Greece, with its University at Athens and a projected one at Salonika; Egypt, Esthonia, Portugal, Japan, Lithuania, Turkey, and Latin America. This is good evidence that the disabilities inflicted on educational studies during the war are now being removed rapidly in an increasing number of countries. The volume comprises a directory of the staffs of the universities of the Empire, an account of the equipment in libraries, museums, and laboratories, under the heading of "general information," and annual reports of the last academic year. The help given by the official registrars and other university correspondents ensures that the information is accurate and recent.

*The Constituents of Coal Tar*,<sup>3</sup> by P. E. SPIELMANN, is one of the series of monographs on industrial chemistry produced under the editorial direction of the late Sir Edward Thorpe; several volumes of this series have already been noticed in our pages, and that now before us is intended to show what kind of things are found in coal tar and what they are like. Any chemist could have named the substances and summarized their properties, but what the author has done is something better. With excellent discrimination he has omitted what was not needed to give his substances individuality; what was needed he has used so well that the materials take character under his description. It is always pleasing to a reader to be made to feel that the author has estimated exactly what he knows already and what other information would interest him most. Speaking for ourselves we find this done with great nicety. We were astonished to find that there was so much of interest to be learnt, and so constituents of coal tar. As inable series, there are ample a good index.

*The Transactions of the American Proctologic Society, 1923*,<sup>4</sup> contains eleven articles on diseases of the rectum and anus; it is a report of the papers presented to this society at the twenty-fourth annual session held at Los Angeles, California. It will be remembered that a large number of the members of this society travelled last year to this country and held their annual gathering in London. They were welcomed by the Proctological Section of the Royal Society of Medicine, and London surgeons had the opportunity of making the acquaintance of some of the proctologists who had contributed to the volume we have before us. The discussions which took place at these united gatherings revealed that in many rectal conditions American practice differs from our own. To those London surgeons who were present at these meetings an added interest will be given to the contents of this volume because of recent friendship with some of the authors.

## THE LISTER INSTITUTE.

The annual general meeting of the members of the Lister Institute was held at the Institute on the afternoon of Wednesday, May 20th. It was preceded by a meeting of the council, at which the resignation of Sir Frederick Andrewes as the representative of the council upon the Governing Body, owing to increasing demands upon his time and energy, was accepted with regret, and Dr. A. E. Boycott, professor of pathology at University College, was elected in his place. At the general meeting the chairman, Sir David Bruce, made an appropriate reference to the loss the Institute had suffered by the death of Professor E. Klein, who had been a member since the amalgamation of the Institute with the College of State Medicine in 1893; of Dr. Horace T. Brown, who had been for a time a member of the council; and of the Marquess Curzon of Kedleston. The council recorded its sorrow at the death of Sir Rickman Godlee, who formerly represented the Royal College of Surgeons of England, and latterly members of the Institute, upon the council; his relationship to Lord Lister gave to his connexion with it a more intimate character than that implied merely by membership of the council. To the vacancy thus caused Professor Starling, who, though a member of the Governing Body, had not previously been a member of the council, was unanimously elected.

### ANNUAL REPORT.

This report of the Governing Body, which is signed by Professor E. H. Starling, acting chairman, gives a good general idea of the multifarious activities of the several departments of the Institute, which, under the general direction of Professor C. J. Martin, have accomplished an enormous amount of work during the year under review.

### Vitamins.

At the present time special interest attaches to the Department of Biochemistry, of which Professor A. Harden is the director, because it is concerned, among other things, with the investigation of vitamins and matters relating thereto. In this department Miss E. H. Hume and Miss H. H. Smith have continued their researches on the influence of ultra-violet radiations on the growth and calcification of bone in rats maintained on deficient diets. Miss Hume has confirmed Steenbock's observation at the Wisconsin Agricultural Station, that lard and olive oil, which are usually devoid of fat-soluble vitamins, acquire the property of promoting growth and calcification after exposure, in a thin layer, to ultra-violet light. The report points out that the discovery permits a rational interpretation of the hitherto mysterious power of light to complement a qualitative deficiency in food supply. This subject is dealt with at some length in the paper by Webster and Hill published elsewhere in this issue (p. 956), and the general conclusion of the Lister report is that "as light of high refrangibility activates, by photodynamic action, some constituent of a crude fat which is otherwise inert, it is not unreasonable to suppose that activation can take place, either before the fat is eaten, or whilst it is circulating in the superficial capillaries of skin which are exposed to sunlight." Miss Harriette Chick, D.Sc., the principal assistant in the Department of Experimental Pathology, over which the Director of the Institute, Professor C. J. Martin, presides, has been studying the amount of vitamin A and antirachitic vitamin in green leaves. She is seeking to ascertain to what extent plants are at for the manufacture of these two. Dr. Zilva and Miss Soames are studying the relative growth-promoting antirachitic potency of butter from pasture-fed and from stall-fed cows when their diet is supplemented with green food, ensilage, and cod-liver oil respectively. This inquiry is being carried out at the National Institute for Research in Dairying at Reading. The active principle of cod-liver oil resides in the non-saponifiable fraction. Professor Drummond at University College has endeavoured to effect a further purification of the antirachitic vitamin. After removal of the soaps, the bulk of the cholesterol is separated and the residue fractionated by distillation *in vacuo*. Miss Soames has conducted the biological assay of the different fractions.

### Tissue Culture in the Investigation of Cancer.

Dr. T. Lumsden has been occupied in investigations concerning the growth of tissues *in vitro*. The use of serum considerably simplifies the method of tissue culture and renders it more readily available for the study of various morphological and bacteriological problems. The experience of previous workers that serum has an inhibitory effect on the growth of tissues *in vitro* has been shown by Dr. Lumsden to be due to allowing the serum to become too alkaline owing to the loss of carbon dioxide by exposure to the air. If this loss be prevented, or compensated by exposing the serum to expired air, both normal tissues and tumour cells can be cultivated in pure serum. By the use of this method he has found that by repeatedly inoculating the cancer of mice or rats into animals of another species, antibodies more or less specific to the cancer cells can be produced. An antiserum prepared in this way has been used as a medium for the cultivation of normal tissues and the homologous cancer cells. In it the normal tissue cells survive and grow for many days, while fragments of the cancer with which the antiserum was produced, placed alongside them in the same culture cell, are rapidly killed. This discovery is being utilized to ascertain whether an antiserum prepared in this way will modify the growth of its homologous tumour in the living animal.

### Inflammation and Nutrition.

In the Department of Bacteriology, directed by Professor J. C. G. Ledingham, Dr. Arkwright, in continuance of his work with Dr. Zilva, has demonstrated the great difference between the inflammatory reaction produced by irritants, according to whether the animal is well or ill nourished. This difference is most obvious in the case of young growing animals.

### Foot-and-Mouth Disease.

Dr. Arkwright has also given a good deal of time to supervising the investigation of foot-and-mouth disease which is being carried out at the Institute for the committee appointed by the Ministry of Agriculture. The chairman of this committee is Sir William Leishman, and among its members are Professor Bullock (a member of the Governing Body of the Institute), Professor C. J. Martin, and Dr. Arkwright. One of the laboratories, together with a suitable isolation and self-contained animal house, has been placed at the disposal of the committee. The work is under the immediate direction of Dr. Bedson, who has the help of Dr. Maitland, formerly acting professor of pathology in the University of Toronto, and Mrs. Burbury.

### Scarlet Fever.

In the Department for the Study and Preparation of Antitoxic Sera attention has been given to recent work in America, suggesting that streptococci present in the throats of scarlet fever patients may be primarily responsible for the disease. Our readers have been kept acquainted with the course of these investigations, conducted largely by G. F. and G. H. Dick. At the Field Department of the Institute, at Elstree, scarlet fever toxin has been prepared, from American strains supplied by Dr. Dochez, for the immunization of horses. The serum of these horses is now being tested therapeutically. That it contains specific neutralizing substances is shown by the fact that it causes blanching of the rash in a certain proportion of scarlet fever cases; also, when introduced in small doses prophylactically in contacts incubating the disease, the rash, when it appears, avoids the skin areas under which the serum has been inoculated. The quantity of serum injected in these experiments was only 2 c.cm., an amount evidently insufficient to produce general prophylaxis. The subject is being further investigated as opportunity offers, and the Biological Standards Committee of the Medical Research Council is arranging for tests with a view to establishing some reliable method of standardizing the serum and toxin. Material for this purpose is being provided by the Serum Department.

We have mentioned only a few of the inquiries in progress, but have said enough to show the great activity displayed by the workers in all departments of the Institute.

SATURDAY, MAY 23RD, 1925.

## LESSONS OF THE HARNETT CASE.

WE publish verbatim, at page 990 of this issue, the judgements delivered in the House of Lords on May 15th in the appeal of Mr. William Smart Harnett. The fact that the unanimous decision of the Lord Justices in the Court of Appeal in favour of Dr. Adam and Dr. Bond has been unanimously upheld by the Law Lords, and that the grave reflections cast upon both Dr. Adam and Dr. Bond by the answers of the jury to questions put to them by Mr. Justice Lush have been shown by the members of both appeal courts to be entirely lacking of foundation in fact, are matters that afford complete satisfaction to the medical profession, since the characters of two of its members, one of whom holds a highly responsible position in the administration of our lunacy laws, are now vindicated beyond cavil.

The facts of the case are set forth in detail in the judgement of the Lord Chancellor. Here we merely wish to refer to certain main issues arising out of the tortuous maze of evidence given in the course of the fifteen days over which the hearing in the King's Bench Division dragged, bearing in mind that all this evidence was given eleven years after the facts occurred, and, human memory being what it is, was somewhat hazy in character.

It was not disputed that on November 10th, 1912, when the original reception order was made, Mr. Harnett was of unsound mind; but Mr. Harnett's condition improved to the extent that, on December 12th, 1912, he was allowed to go home for twenty-eight days on a leave of absence on trial order, made under Section 55 (3) of the Lunacy Act, 1890—in a form settled by the law officers of the Crown—which stipulated that the medical officer should at any time before the expiration of twenty-eight days have power to take back the said patient into the licensed house "if his mental condition requires it." Mr. Harnett left the mental home at Malling Place with his brother, but on the morning of December 14th he called at the offices of the Commissioners in Lunacy in Victoria Street, London, apparently for the purpose of asking that he be put in the care of the police and not of his brother. What happened at the offices is not quite clear from the evidence, but the Law Lords accepted the facts that both the secretary, Mr. Dickinson, and Dr. Bond thought Mr. Harnett was in an excited state and unfit to be at large, and that, after identifying Mr. Harnett's case in the files, they telephoned to Dr. Adam their opinion. Upon this, Dr. Adam sent a car and fetched Mr. Harnett back to Malling Place, where he examined him, and, finding him worse mentally than when he was released on trial, detained him under the original reception order. Mr. Harnett stayed at Malling Place until February 22nd, 1913, and thereafter he was confined at different asylums until October 15th, 1921, when he escaped. (Owing to the anomalous Section 85 of the Lunacy Act, 1890, which says that an escaped lunatic can only be retaken within fourteen days of escape without a fresh order or certificate, Mr. Harnett, by eluding recapture for that period, regained his liberty and was declared sane by eminent alienists whom he consulted.

The action against the two doctors was not founded

in negligence, as was the case in *Everett v. Griffiths and Anklesaria* (1920, 3 K.B. 163; 1921, 1 A.C. 631), but in conspiracy and false imprisonment. The allegation of conspiracy was dropped early in the course of the proceedings, and was clearly negatived by the jury by their answers to questions 13 and 14. There remained the allegation of false imprisonment, and the jury, by their answer to question 17, found that Dr. Adam was not responsible for the false imprisonment. It was admitted all along by counsel for Dr. Bond that Dr. Bond was responsible for the detention in the Commissioners' offices on December 14th, 1912, and his liability in damages for this act followed from the jury's finding that Mr. Harnett was sane on that date. It was not open to Dr. Bond *qua* Commissioner to plead the protection afforded by Section 330. This is now the only point left open: a new trial has been ordered for a jury to determine these damages for a period of detention which, the Lord Chancellor said, in a just view could not extend beyond 7 o'clock of December 14th.

The Lord Chancellor characterized it as a remarkable fact that no direct question was put to the jury either as to the alleged conspiracy or as to the alleged false imprisonment. Dr. Adam not being found liable for false imprisonment, there was no further ground of action against him on the statement of claim, and the question of negligence arose out of his defensive plea of Section 330—open to those who act *bona fide* and with reasonable care in pursuance of the Lunacy Acts. The *bona fides* of Dr. Adam was clearly established by the jury's answer to question 13, but in their answer to question 15 they said that he did not take reasonable care in exercising his power to retake Mr. Harnett (under the leave of absence order). Mr. Harnett's counsel throughout advanced the amazing contention that the medical officer had no power of recapture outside the mental home, and that a recertification was needed before Mr. Harnett could be brought back unless "his mental condition requires it." As the jury had found that Mr. Harnett was sane on December 12th, it followed from this argument that Dr. Adam had not, in fact, exercised that reasonable care which afforded him the protection of Section 330. The Lord Chancellor scotched this argument. Such a provision as "if his mental condition requires it" could not, in his view, mean that the medical officer was to take back the patient at the risk of having it found by inquiry many years after that the patient's mental condition was consistent with his remaining at large. The medical officer was the judge of the patient's mental condition, and in him the power to retake the patient rested, and that power was capable of being exercised wherever the patient might be found. The argument that the onus was upon Dr. Adam to prove that he had exercised reasonable care was also described by the Lord Chancellor as fallacious. If such a power was exercised negligently the remedy (if any) would, of course, be by an action for negligence and not for false imprisonment, but the Law Lords agreed with the Court of Appeal that there was no evidence to substantiate the jury's answer to question 15 that Dr. Adam had not taken reasonable care. The case against Dr. Adam was thus shown to be built on the flimsiest of foundations—inferences of fact and law which three Lord Justices and five Law Lords have unanimously agreed ought never to have been drawn. Further, the Law Lords disapproved of the form of some of the questions put to the jury, particularly questions 7, 8, and 9, to which the jury answered that Dr. Bond did not honestly believe that the plaintiff was of unsound

mind, or that he was fit to be at large, or was dangerous to himself or others. The Lord Chancellor pointed out that it was common ground that the effect of the jury's answer to question 10 was that Dr. Bond's belief that the plaintiff had escaped from his brother's charge was the reason for his having Mr. Harnett sent back. But we agree with Lord Buckmaster that this explanation of the earlier answers of the jury is inadequate. Even assuming that Dr. Bond may have made a mistake—and from certain observations which Lord Buckmaster made in the course of the hearing in the House of Lords we infer that he, at any rate, did not think Dr. Bond had made any mistake at all—he could find nothing in the evidence that on any interpretation of the word could cast the least reflection on his honesty: "I think it is to be regretted that a question should have been left to the jury in such a form that the verdict taken upon it must, in the plain meaning of the words, cast a reflection upon Dr. Bond's character which no sophistry can explain away."

The most disturbing aspect of the Harnett case to the medical profession was that of the doctrine enunciated by Mr. Justice Lush—the doctrine of continuing responsibility. Heavy damages were the fruits of the direction of Mr. Justice Lush to the jury: "taking into consideration the whole purpose for which he was so detained." The Lord Chancellor said the findings on damages were "obviously coloured" by such and similar directions. We have, in discussing the case a year ago, described as amazing the dictum of Mr. Justice Lush that once a man is certified insane each subsequent certification by a doctor and each adverse report by a visitor is a mere formality, a mere act of omission to find the patient sane, and not a new act intervening to break the chain of causation. The Lord Justices, fortunately for the medical profession, took a different view of the law, and held that this chain had been broken at "innumerable points." It appeared to the Lord Chancellor to be impossible to hold that the detention of the appellant at the offices for a few hours was the direct cause, not only of Mr. Harnett's being retaken and conveyed to Malling Place, but also of his being confined in that and other mental homes until October, 1921. Dr. Bond could not, he said, on any intelligible principle, be held to be responsible for the consequences of those events; Lord Dunedin looked upon such a suggestion as preposterous.

Medical men are now free from the fear they quite legitimately entertained after the judgement of Mr. Justice Lush: that when they certify a patient it is possible that a jury, sitting some years hence, may find that selfsame patient to have been sane on the date of the original certification, and that the doctor responsible for such certification may be made liable in damages for the whole period of detention, in spite of the many subsequent independent certifications by other medical men during that period.

But we do realize, with the Lord Chancellor, that the verdict of the jury and the heavy damages they gave against Dr. Adam and Dr. Bond were the outcome of a belief that Mr. Harnett was quite sane during the whole period from 1912 to 1921, though there was no actual finding that Mr. Harnett was sane after December 12th, 1912. This fact, as the Lord Chancellor said, gives rise to anxiety, though we agree with him that even if Mr. Harnett was sane during his confinement it was no reason for visiting vindictive penalties upon persons who acted in good faith and who were not responsible for any defect in the law.

The Lord Chancellor enumerated the existing safeguards, and said it might be—"I do not say that it is"—the fact that all these precautions are insufficient, and that the lunacy laws require to be further strengthened in the interests of the persons whom they may affect. The proceedings in the Harnett case in the King's Bench Division were the direct cause of the holding by a Royal Commission of the inquiry into the administration of our lunacy laws, and we look forward with interest to the publication of its findings. While we have always insisted that the public at large must be protected against the dangers to which it would be exposed if lunatics were allowed to move about unrestrained, we have always placed as much, if not more, emphasis upon the protection of the individual against improper confinement. We have on several occasions urged that the hard-and-fast legal procedure in England should, in the interest of the patient, be approximated more nearly to the Scottish methods, as in their early stages many forms of mental disorder are curable by suitable treatment, for which statutory provision should be made.

Whatever new legislation may be the outcome of the Royal Commission, the members of the medical profession will continue loyally to administer the lunacy laws, and to discharge those large responsibilities which have been placed upon them on the theory that they can be trusted; and, now that the final decision in the Harnett case has shown that Section 330 is a sure shield to all medical men who act *bona fide* and with reasonable care in pursuance of the lunacy laws, they will feel, while performing their tasks, a sense of security which would have been grievously lacking if the judgement of Mr. Justice Lush had been allowed to stand.

### THE SPREAD OF SMALL-POX.

AN incidental effect of the renewed prevalence of small-pox since its minimum in 1917 is the resumption of the outpouring of letters to the press by opponents of vaccination whose knowledge of the subject is in inverse ratio to the assurance they display in dealing with it. So long as variola retains the mild form which is now presented in most countries—a form which Jenner described as occurring epidemically in 1789—it may be thought hardly worth while to pay any attention to the influence of such commentators. Fortunately the children who are being attacked by small-pox, owing to their parents' neglect to have them vaccinated, are being vicariously punished much more lightly than they would have been in the nineteenth century, and while that remains the case there is temptation to treat the silly dialectics of the letter-writers with silent contempt. But there is probably some risk of sober-minded people misunderstanding the silence, and from that point of view we shall call attention to some statistics which Dr. C. G. Pearce, senior surgeon to the United States Public Health Service, Chicago, has published in a recent issue of the *Boston Medical and Surgical Journal* (April 9th, 1925).

Dr. Pearce's data are based on the records of the United States Public Health Service relating to all quarters of the globe. Small-pox, he observes, remains the most widely distributed plague in the world, there being practically no country permanently free from it. During the year ending June 30th, 1924, 149,550 cases of small-pox with 22,346 deaths were reported by health officers throughout the world to the United States Public Health Service. One-fifth of all these cases occurred in the United States, forty-

five States reporting a total of 30,771 cases. Apart from China and India, during 1923 only three countries in the world where vital statistics are kept and are available exceeded the United States in their small-pox rate. These countries were Switzerland, Russia, and Greece, which had rates respectively of 55, 43, and 33, as compared with 27.1 per 100,000 in the United States. On the other hand, in South Africa, Egypt, Algeria, Finland, Hungary, and the Baltic republics the small-pox rate ranged from 3.9 to 0.35 per 100,000, while the Scandinavian countries, Australia, and New Zealand reported no cases at all. During 1924 3,073 cases occurred in Minnesota with 306 deaths—a mortality of 9.9 per cent. Of the 306 fatal cases none had been successfully vaccinated within seven years, and 243 had never been vaccinated. Forty-seven had been vaccinated, but the successful vaccinations ranged from eight to seventy-five years before the fatal attack, and in 16 there was no definite history of vaccination. In an outbreak at Windsor, Ontario,<sup>1</sup> there were 67 cases and 32 deaths between December 12th, 1923, and March 17th, 1924. Within two weeks over 50,000 persons were vaccinated, and the epidemic promptly subsided. The outstanding features of the epidemic were that all the deaths occurred in unvaccinated persons; that seven out of every ten unvaccinated persons who contracted the disease died, the fatality among the unvaccinated being 71 per cent.; one man, aged 80, who had been vaccinated sixty years before, and who lived in the same house as a man with malignant small-pox, developed a mild attack from which he quickly recovered. The rapid increase that may occur in the virulence of a small-pox epidemic is shown by the experience of Detroit. Between September 1st, 1923, and March 15th, 1924, 710 cases occurred with only 4 deaths. On the other hand, during the period March 16th to June 1st, Detroit had 795 cases with 105 deaths. Exclusive of the cost of the patient's treatment in hospital, which amounted to \$2.39 a day for each patient, the epidemic cost the Health Department of Detroit \$127,854, and it was calculated that the time lost on account of 784 persons who had small-pox between April 13th and August 31st, 1924, was 163 years, 8 months, and 17 days.

A telegram from the *Times* correspondent in New York, dated May 17th, states that that city has voted \$80,000 (£16,000) for a special campaign by the Health Department to prevent the spread of small-pox. There were, he said, "only six cases in the city at that time, but the prevalence of the disease in Philadelphia, Camden, and some neighbouring suburbs has led the health commissioner of New York to emphasize the need for precaution, especially as most of the cases reported throughout the country in recent weeks have been of a virulent type, with a large percentage of deaths."

While this is the position in America the infection continues to spread in England. In the first four months of this year the total number of cases reported has been 2,393. According to the record in the Registrar-General's reports, the weekly numbers, from January 3rd to May 2nd, which began with 91, have mounted gradually to 176 in the seventeenth week, the highest figure so far reached. In the eighteenth week 162 cases were notified. The North of England and the Midlands have been mainly affected, Northumberland, Yorkshire, Derbyshire, Nottingham, and Northampton all being involved.

The health officers of the great cities of the industrial

region cannot but be in continual anxiety, especially if the disease prevails in rural or urban districts near them. The fact that they have hitherto been largely successful in keeping the disease at bay is most creditable, and their continued success will be watched with keen interest. The cost to the public funds is mentioned by Dr. Pearce in respect of America, and is receiving attention in places affected in this country. There have even been mutterings of abandonment of hospital isolation, and resort to such segregation as might be possible at home. That is a counsel of despair to which the public health service of this country is unlikely to listen. It is quite true, however, that the task of the medical officer of health is now made extraordinarily difficult. He has to contend with concealments of recognized cases, with failures to recognize the disease, and with much neglect of vaccination even in some localities where small-pox has been prevalent. He struggles to discover contacts, but in the circumstances there is great risk of lists being incomplete, and he may well feel the task almost hopeless. Where the infection has already taken firm hold of a community the only course is to continue trying to wear down the enemy by steady perseverance in vaccination, isolation, and search for contacts. In some places control has been accomplished by such means and the disease gradually extirpated. Where the invasion is only beginning, vigilance from the very onset is the only policy. The officer should waste no time in academic discussion of what he ought to call the malady, whether alastrim or small-pox or parsmall-pox, or what else. His duty is to try to stamp it out and leave such topics for elaboration after he has done so. A complete list of contacts, with surveillance of them from the very beginning, is of infinitely more value than the devising of appropriate names for purposes of registration. Also, it seems to us that in the present circumstances of this country, and with the present type of small-pox, local health authorities may as well cry for the moon as for absolute compulsion of vaccination. If Parliament is wise it will exercise all reasonable pressure, and will at least reverse Mr. Wheatley's withdrawal of the order issued by Mr. Neville Chamberlain when previously at the head of the Ministry of Health, regarding the form of vaccination notice to parents; the altered form is as much an invitation to omit vaccination as a request for its performance. In the meanwhile the basic fact remains that every parent who chooses to do so can by vaccination and revaccination of himself and his family obtain complete protection against small-pox, whether mild or severe, diagnosed or undiagnosed, isolated in hospital or left uncontrolled. And for the instruction of such part of the public as is willing to accept instruction the data collated by Dr. Pearce from the United States Government's reports are to be added to the great store already available.

#### SLEEPING SICKNESS CONFERENCE.

An international conference on sleeping sickness is being held in London this week under the chairmanship of Mr. Ormsby-Gore, Under Secretary of State for the Colonies; the other British representatives are Dr. Andrew Balfour, C.M.G., director of the London School of Hygiene and Tropical Medicine, and Dr. A. G. Bagshawe, C.M.G., director of the London Bureau of Tropical Diseases. The conference is being attended by representatives of France, Italy, Belgium, Portugal, and Spain. A committee of experts nominated by the League of Nations in 1922 to obtain information as to the prevalence of sleeping sickness and to

! Africa made a series

<sup>1</sup> See the *British Medical Journal*, March 23rd (p. 534) and July 19th, 1924 (p. 123).

of recommendations, which were approved by the Council of the League of Nations at its session in Rome last December. One of the recommendations was that such a conference as is now meeting should be held. In opening the proceedings on Tuesday last, Mr. Ormsby-Gore said that one of the outstanding problems encountered during his recent tour in Central Africa was that of the human and animal diseases the infection of which was carried by tsetse flies. The tsetse fly, he said, occurred in belts of varying sizes practically throughout the whole of tropical Africa from Senegal on the north-west to Zululand on the south-east. The great outbreak of sleeping sickness in Uganda about twenty years ago, when roughly one-tenth of the total population of the protectorate died, had attracted much public attention in this country. The disease, though less severe, was still prevalent in Uganda, and a report from Northern Rhodesia had been received stating that an epidemic outbreak of a severe form occurred in 1923 in an area where its presence had not previously been recorded. The position was serious also in the Belgian and French colonies, including those in West Africa; one of the most important pieces of work in connexion with the problem had been carried out in the Portuguese island of Principe, and at the present time the disease caused grave anxiety in the Spanish island of Fernando Po. In 1900, shortly after the great outbreak in Uganda, an international conference was held in London; it met again in the following year; a general agreement was not reached, but Great Britain founded the Sleeping Sickness Bureau. During the outbreak in Uganda and Nyasaland in 1908 it was discovered that the infection was carried there, not by the tsetse, *Glossina palpalis*, which was the vector in Uganda, but by *Glossina morsitans*, which conveyed trypanosome diseases to domestic stock. The investigations of Dr. Kinghorn and Dr. Yorke in Northern Rhodesia, and of the Royal Society Commission under Sir David Bruce in Nyasaland, led to the appointment by the then Secretary of State for the Colonies of a committee; its report was presented to Parliament in May, 1914, but the outbreak of war a few months later prevented any immediate action. Other nations had taken the matter up, and Dr. Kleins had ascertained that a developmental cycle of the trypanosome occurred in the tsetse fly. Investigations into the treatment and prevention of the disease by the use of drugs were instituted by French, German, Belgian, and American scientists, but though questions of this nature have not yet been answered the most important problems at the moment were administrative. In Central Africa, where native social life and custom was so intimately bound up with the keeping of cattle and other domestic stock, the problems of sleeping sickness could not be dissociated from those of animal trypanosomiasis (nagana), and Mr. Hornby of the Tanganyika Veterinary Institute had made some valuable observations on the treatment of nagana, but the inquirers were everywhere brought back to the physical and administrative problem of the control and eventual extermination of the tsetse fly itself. The task was tremendous, but there was hope, and if the problem could be solved something very notable would be done for the African native and for the advance of civilization and development in Africa. Mr. Ormsby-Gore then referred to what he described as the very remarkable achievements of Mr. Swynnerton in the Shinyanga district of the Tanganyika Territory (of which that investigator gave some account in our columns not very long ago), and to what had been done by Father Cirvenga in another part of the same territory. During a visit to Shinyanga Mr. Ormsby-Gore had been able to satisfy himself that the experiments, which were on a considerable scale, were being attended by a large measure of success. The conference had been summoned to discuss the possibility of carrying out the recommendation of the League of Nations Council that a special international epidemiological

commission should be sent to equatorial Africa. The terms of reference to the conference suggested that attention should be concentrated on the purely medical aspects of the problem as it affects sleeping sickness in man, but it was hoped that all sides of the question would be considered. The object of the commission, therefore, would be to survey the fly areas of tropical Africa, noting any extension or decrease, to make further researches into the bionomics of the tsetse fly, to make experiments on a field scale for the extermination of the fly, and to investigate the prevention and treatment of both human and animal trypanosomiasis. For such a task there would be required the services of entomologists, protozoologists, veterinary and medical scientists, and men of administrative and zoological experience such as Mr. Swynnerton.

#### THE PROJECTION OF THE RETINA IN THE BRAIN.

There appear to be two main schools of thought with regard to the projection of the retina in the brain. The one, led by Henschen, holds that every spot on the retina has a definite localization in the external geniculate bodies, in the optic radiations, and in the cerebral cortex of the occipital lobes. According to this view the macula is represented by a circumscribed area in the brain, and the dorsal or uppermost part of the retina is represented in the upper part of the geniculate body, radiation, and cortex. The other school, led by von Monakow, denies that each part of the retina has a definite localization, and holds that the macula is represented over a wide area. Dr. B. Brouwer, professor of neurology in the University of Amsterdam, in a lecture delivered at Charing Cross Hospital Medical School on May 15th, described the views of these two schools, and showed how recent work carried out by him had led him to take an intermediate position. He referred to the work reported by Holmes and Lister during the war, which went to support Henschen's theory. These workers found that bullet wounds of the occipital lobe caused localized patches of blindness in the fields of vision. His own method of investigation has been to enlist the aid of an ophthalmological colleague to make localized lesions in the retinae of experimental animals; these were killed some time later, and the areas of degeneration in the brain were then examined histologically after being treated by the Marchi method. In this way Professor Brouwer has been able to study the brains of some sixty animals. In rabbits, where a very high proportion of the optic tract crosses, the principle of an exact localization of each part of the retina in the external geniculate bodies was completely upheld. In cats, where more fibres appear to be uncrossed, this localization was still found to be fairly exact. Further experiments were then carried out on monkeys in which the arrangement of the optic tracts and the existence of maculae rendered the conditions very similar to those existing in man. The results in these cases were somewhat more difficult to interpret on account of the fact that there is only a small portion of the field of vision which can be seen by one eye alone, but the inner part of the retina, which is the part concerned with monocular vision, had been destroyed in certain monkeys, and areas of degeneration were found to exist in a localized portion of the lower part of the external geniculate body of the opposite side. The areas of degeneration corresponding to lesions of the macula were not small, but were spread out over a great deal of the external geniculate bodies of both sides. The parts of the retina nearest to the macula were represented in areas of the geniculate bodies nearest to the areas of macula projection, and the periphery of the retina was represented around the periphery of the geniculate bodies. Professor Brouwer thus agrees with Henschen as far as localization of retinal projection is concerned, and with

von Monakow in the matter of a large area of projection for the macula. He is at present engaged on further work in which he hopes to trace the projection of the retina in the cerebral cortex. He has also given a lecture on this subject at the University of Sheffield during the present week.

#### AMERICAN POST-GRADUATES IN LONDON.

THE programme of the visit to London of the Inter-State Post-Graduate Assembly of America from June 2nd to 4th is now complete. Arrangements have been made for lectures (at Wigmore Hall) in the mornings, beginning at 9.30, and hospital visits in the afternoons, continuing until 5 o'clock or later. In order that no time may be lost after lunch a fleet of motor buses has been chartered to convey the visitors to the hospitals. Following the inaugural ceremony by H.R.H. the Duke of York on the first morning there will be four consecutive lectures, each lasting half an hour, and on each of the next two mornings six such lectures. The chairmen at the three morning sessions will be Sir Humphry Rolleston, Sir John Bland-Sutton, and Sir StClair Thomson respectively. Sir Humphry Rolleston is to open the lecture list with a discourse on gall-bladder disease, and he will be followed by Sir W. Arbuthnot Lane on "The first and last link," Sir Thomas Horder on "Changes in the incidence and course of common diseases," and Dr. A. F. Hurst on "The pathogenesis and treatment of Addison's anaemia and subacute combined degeneration of the spinal cord." On the second morning Professor H. Maclean lectures on renal disease, Mr. A. J. Walton on gastro-jejunal ulcer, Colonel L. W. Harrison on the combating of venereal disease by free treatment centres, Mr. W. E. Miles on cancer of the rectum, Mr. T. P. Dunnhill on auricular fibrillation in exophthalmic goitre from the point of view of surgical treatment, and Dr. Strickland Goodall on the heart in influenza. On the final morning Dr. Gordon Holmes takes for his subject suprarenal disease, Sir Walter Fletcher medical research in Great Britain, Mr. James Sherren the choice of operations in gastric and duodenal ulcer, Sir StClair Thomson cancer of the larynx, Dr. H. C. Cameron functional nervous disturbances in children, and the last lecture is by Lord Dawson of Penn, whose subject is "The speed of life and disease." Post-graduate programmes for the afternoons have been offered by thirty-four general and special hospitals, the number of visitors to each institution being limited usually to twenty or thirty. The programmes generally include a round of the medical wards, surgical operations, clinical and pathological demonstrations, visits to special departments, the exhibition of historical and other specimens, and in some cases brief lectures. Practically the whole of each hospital staff will be at the service of the visitors. The institutions offering this hospitality include the Radium Institute and the London School of Hygiene and Tropical Medicine. On June 3rd the Royal Society of Medicine will give an evening party, when Mr. W. G. Spencer, honorary librarian of the Royal Society of Medicine, will exhibit over fifty examples of American medical literature before 1861. The executive committee, which is responsible for the arrangements as a whole, including a number of social functions in the late afternoons and evenings, consists of Sir Humphry Rolleston, Sir W. Arbuthnot Lane, Sir StClair Thomson, Sir William Hale-White, Sir Holburt Waring, Mr. W. Girdling Ball, and Mr. Philip Franklin (honorary organizer). The medical programme committee consists of more than forty members, under the chairmanship of Sir Holburt Waring, and there are four honorary secretaries—namely, Professor Arthur Ellis (medical), Mr. W. Girdling Ball and Mr. H. W. Carson (surgical), and Dr. Eric Pittchard (special departments). The bureau and headquarters will be at the house of the Medical Society of

London, in Chandos Street, Cavendish Square, where also an exhibition of surgical instruments and medical products has been arranged. The Inter-State Post-Graduate Assembly of America, which is directed by the Tri-State District Medical Association, comprises, it is stated, 55,000 members. The number accompanying the President, Dr. Charles Mayo, to Europe on this occasion is expected to be about 300. The London visit will be followed by visits to Ireland, Scotland, and the English provinces, and later in the month the party will proceed to Paris, where Professor Tuffier has charge of the arrangements.

#### WELSH CRIPPLES.

As readers are aware, a movement for the better treatment of cripples and for their education during treatment has been making steady progress in England. An account of the position then reached was given in our columns on August 2nd, 1924 (p. 204), and since then meetings have been held in many counties, with the result that much public interest has in every instance been aroused. It is primarily a matter for the education authorities, but they require support and stimulation, and those concerned in the movement are in need of funds to carry on the crusade. The movement, although it originated in the marches of Wales—in Shropshire, at Baschurch, in the institution established by Miss Hunt—has not yet made much progress in the Principality. We are glad to learn, however, that attention is now to be given to the matter. The Welsh National Memorial Association, established for the treatment of tuberculosis, has already done a good deal by setting up hospitals at which non-pulmonary tuberculosis is treated. There is the North Wales Sanatorium at Llangwylfan, near Denbigh, the St. Bride's Hospital, recently opened in Pembrokeshire, and the Glan Ely Hospital, Cardiff, to mention only some of the largest. In this connexion the Prince of Wales's Hospital established in Cardiff during the war for the treatment of soldiers and sailors who had lost a limb should be mentioned. In its foundation Sir John Lynn-Thomas took the initiative, Lord Tredegar gave the site, and Mr. Percy Miles and some other wealthy men in Cardiff made large contributions for its equipment and endowment. The number of war cases has now largely diminished, and the hospital has been able to undertake the treatment of civilian cases from all parts of Wales and Monmouthshire. In addition to residential ward accommodation, which is already being largely utilized for children, it possesses workshops and exercising grounds, where the cripple can receive his earliest instruction. Sir John Lynn-Thomas, who is at present himself, we regret to learn, physically crippled by a fracture into the knee, sustained early in March while on a visit to Florida, is not allowing this handicap to interfere with the planning of a national scheme for Wales. A gift of £50,000 from an anonymous donor, to meet preliminary expenses, has just been announced. This gift and other contributions which may be received will be vested in trustees, whose first duty it will be to take a census of cripples; it is estimated that there must be at least 20,000 cases in Wales and Monmouthshire who need orthopaedic treatment. The English scheme, which owes its present advanced position largely to the leadership of Sir Robert Jones, is to be extended, with suitable modifications, to Wales, and the Prince of Wales's Hospital at Cardiff will, it is thought, offer suitable headquarters. It is intended to hold a conference in the autumn to which every health and education authority in Wales and Monmouthshire will be asked to send representatives. The scheme will then be fully explained by Sir Robert Jones and others, and, it is hoped, very shortly thereafter brought into action. It has the support, we understand, of the Welsh Board of Health and the Welsh Board of Education.

## INTERNATIONAL CONGRESS OF RADIOLOGY.

THE International Congress of Radiology, which is to be held in London from July 1st to 4th, will consist of three sections—radiology, physics, and electrotherapy and physiotherapy. As the number of papers in the section of radiology is very large it will probably meet in two divisions sitting simultaneously, the one hearing and discussing papers relating to diagnosis, and the other those bearing on therapy. The section of electrotherapy and physiotherapy will hold three sessions; the first dealing with actinotherapy, and the second with diathermy. In the physics section Professor Hopwood will open a discussion on the organization of a hospital radium service. On the opening day that section will meet with the section of radiology for a discussion on the standardization of dosage, which will be opened by Sir William Bragg from the physical standpoint, and by Dr. Bédère of Paris from the medical. On the evening of that day the Duc de Broglie will give the Sylvanus Thompson memorial lecture, and has chosen for his subject the absorption of  $\alpha$  and gamma radiations and the secondary radiations which accompany them. On July 3rd Sir Berkeley Moynihan will deliver the Mackenzie Davidson memorial lecture on the relation of radiology and surgery. The congress dinner will be held on the evening of the second day.

## SPOKEN AND WRITTEN ENGLISH.

PROBABLY few people realize that the distinction implied in the above title exists. Dr. Henry Bradley, the senior editor of the *Oxford English Dictionary*, read a paper on the subject at the International Historical Congress as long ago as 1913. It has lately been reprinted by the Society for Pure English. It is a thoughtful pamphlet, and will well repay perusal. Dr. Bradley began by laying it down that, little as the fact may be realized, "speech and writing are two organs for the expression of meaning, originally co-ordinate and mutually independent." He thought it probable that written language was primarily ideographic, conveying ideas by means of a series of pictures, and that only secondarily did it become representative of the sounds of speech. Many educated persons do not appreciate to what an extent they read the written word, not as a combination of sound symbols, but as an ideograph or single symbol, the sight of which calls up in the mind the memory of a thing or an idea; we all know that when in doubt as to the spelling of a word we can often come to a right decision by "the look of it," on comparing the two spellings when written. Ideographical language still preserves traces of its twofold origin, and among modern tongues English more than most shows differences between the written language of the educated and the spoken language of the multitude. This "undemocratic" character of the literary language is exaggerated by the classical tradition and by the number of words which have been borrowed and adapted from the dead languages, and of late years especially by the host of words coined mainly from the Greek to represent technical and scientific ideas and discoveries. Dr. Bradley expressed the opinion that many of these are scarcely used in the spoken language. The German method of Teutonizing every term does not recommend itself, for if the speakers of all languages followed it a scientific tower of Babel would be erected with dire results. He suggested that by international agreement all new scientific technical terms might be expressed in Esperanto or in some better universal language yet to be invented and adopted. While he looked upon radical spelling reform as impracticable, he admitted that the adoption of phonetic spelling would have some distinct advantages, among which not the least would be the greater ease of learning to spell and read and write. In a note on spelling reform he confessed that his ideas were ex-

ceedingly vague as to the extent to which reform is possible and desirable, but he thought that reformers should for the present confine the attack to those points for which there is no defence but custom. The number of homophones or words sounding alike but spelt differently and with different meanings constitutes a difficulty. If the "p" in "psychosis" and suchlike words were habitually sounded we should abolish the anomaly under which a mental derangement and a skin disease are represented by the same sounds. As regards the teaching of correct pronunciation, it must be remembered that a phonetic notation which represents correctly all the sounds in the language is something quite distinct from the more debatable phonetic spelling, which might correctly represent the speech of the educated Londoner but not that of the Aberdonian scholar, and which also might be gradually rendered inaccurate by changes of customary pronunciation, as has happened with many words in use to-day. In Chinese an ideographic character may represent all the widely differing sounds given to the same word in many dialects the speakers of which are mutually incomprehensible; consequently the written language is not subject to the same changes as are found in the alphabetical languages that attempt to convey the sounds of speech by written words.

## WAR MEMORIAL TO WOMEN.

THE famous Five Sisters Window of York Minster, which has been restored by women of the Empire in memory of women who gave their lives in the war, will be unveiled by the Duchess of York on June 24th at 3 p.m. An oak screen has been placed in the Minster with the names of the women to be commemorated. There are several women doctors on this roll of honour, and it is hoped that as many of their colleagues as possible will be present on this occasion to pay tribute to their memory, whether they did war work or not. As all representatives will be wearing uniform, it is requested that all medical women present shall wear academic dress. All who have decorations are asked to wear them. During the time of the ceremony at the Minster memorial services will be held throughout the Empire—in Australia, Canada, and New Zealand. The railway companies will give special terms—return tickets will be issued at one and a third single fare, or, for parties of twelve and over, at the price of the usual single fare. Dr. Louise Fraser has organized the medical deputation, and it is asked that applications should be made to the honorary secretaries, Women's War Memorial, Assembly Rooms, York, as early as possible.

THE "BRITISH MEDICAL JOURNAL":  
NEW ADDRESS.

DURING the Whitsun holidays the Editorial and Printing Departments of the *BRITISH MEDICAL JOURNAL* will be removed from 429, Strand, to the new headquarters building of the British Medical Association in Bloomsbury. After Thursday, May 28th, the postal address for all communications intended for the Editor will be "*BRITISH MEDICAL JOURNAL*, British Medical Association House, Tavistock Square, W.C.1," the telephone number of the Editorial Department will be Museum 9864, and the telegraphic address "Aitiology, Westcent, London." Until further notice is given in these columns, all communications with reference to advertisements, as well as orders for copies of the *JOURNAL*, should continue to be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2. It is expected that the Medical Department and the Library of the Association will be removed about June 17th, and the Finance Department about June 19th.

## THE ASSOCIATION'S NEW SCOTTISH HOUSE.

RESULTS have amply justified the policy of the Council of the British Medical Association in granting a measure of devolution to Scotland: first by the establishment in 1903 of a Scottish Committee with a remit to "report to the Council on any matters specially concerning Scotland"; and, secondly, by the appointment in 1919 of a whole-time Scottish Medical Secretary (Dr. J. R. Drevor), and an enlarged remit to the Scottish Committee to "consider all matters specially concerning Scotland, and, in conformity with the decision of the Representative Body, deal with all such matters." Premises in Rutland Square, Edinburgh, were secured for the Scottish Office. A quickening and deepening of interest in the affairs of the Association among the members in Scotland and a notable increase in membership have ensued from these changes.

With the membership of the British Medical Association touching 3,000 in Scotland, and still increasing, and with the Scottish Committee bearing its share of the growing activities of the Association, the Council, in December last, cordially approved a recommendation of that Committee that "it is desirable that the Association should own its own house in Scotland." Suitable premises were found in the property occupied by the late Dr. Brewis, at 6, Drumshough Gardens, Edinburgh, and were acquired by the Council. The Scottish Office is now in occupation there, and a ceremonial opening has been fixed for Thursday, June 4th.

No. 6, Drumshough Gardens, Edinburgh.  
Sited in one of the noblest of Edinburgh's many noble

streets, in the heart of the west end, and convenient of access from all parts of the city, the building in Drumshough Gardens is in every way suited to its purposes. Its four floors offer more accommodation than is required for the immediate needs of the Scottish Committee of the Association, and the upper two floors have been let on lease to the Meteorological Office of the Air Ministry. On the ground floor the Scottish Medical Secretary and his staff have been housed in a handsome suite of offices, and on the first floor there is a hall with seating accommodation for 150, with ante-room and cloak rooms. The hall will serve as a Committee and Conference Room, as well as for Divisional and other meetings. It is hoped that kindred professional societies may find in it a convenient meeting place, and already the Edinburgh Medico-Chirurgical Society and the Edinburgh Obstetrical Society have arranged to hold their June and July meetings there.

The opening ceremony on June 4th is to take the form of a luncheon in the new house, to which a number of distinguished guests have been invited. The Secretary for Scotland, the Right Hon. Sir John Gilmour, Bt., D.S.O., has accepted an invitation to be present. The chair will be taken by Dr. C. E. Douglas (Cupar, Fife), Chairman of the Scottish Committee of the Association.

## Scotland.

## MAN'S EVOLUTION.

A REPORT of the first three of the course of Munro Lectures on the evolution of man, delivered by Sir Arthur Keith at the University of Edinburgh, was published last week (p. 941). In the next lecture he dealt first with the remarkable race of mankind which inhabited Europe throughout the long period of Mousterian culture from 40,000 to 20,000 years ago, and ended abruptly with the advent of the Caucasian. The existence of Mousterian Europe had been first disclosed by a gang of German navvies who were clearing out the Neanderthal cave north of Düsseldorf in 1857, and had found in the strata a fossilized human skeleton. This was fourteen years before the appearance of Darwin's *Descent of Man*, and the anatomists of the time had concluded that they were dealing with a descendant of Noah who had strayed into Europe after the flood had abated. By good fortune Sir Charles Lyell obtained a cast of the skull, and he and Huxley had recognized that it was both ancient and primitive, and moulded on ape-like lines. More recently a score of men and women of this ancient Neanderthal type had been discovered, and much had been elucidated by taking casts of the interior of their skulls in regard to the size, shape, and pattern of the brains. Stone implements of this period had been discovered showing high skill, resource, and a power of invention. It had also become known that the men of that time knew the uses of fire, were expert

hunters, and buried their dead with ceremony, laying with them implements, ornaments, and apparently joints of meat. All these facts had come to light in the course of explorations during the present century. This civilization had disappeared 20,000 years ago when our ancestors, the Caucasian pioneers, made their way into Europe. There did not appear to have been any interbreeding between the two races, although the Caucasians had apparently existed in Europe during the period of Mousterian culture, for both in the valley of the Thames and the valley of the Seine the bones of Neanthropic or Caucasian man had been found embedded in strata of a pre-Mousterian date, and this led to the supposition that men of our type had broken into Europe and obtained a temporary foothold before their final settlement at the end of the Mousterian period. In the fifth lecture the most ancient English person, probably a woman, whose skull had been discovered at Piltdown in the county of Sussex, was discussed. This went back some 10,000 years to the point where the present period of the earth's history began and where the Pleistocene period ended. The Piltdown fragments were found in a bed of gravel laid down by the Ouse of Sussex, before that river had eroded its valley, which is now over 80 feet in depth. From subsequent discoveries it appeared that this Piltdown race had mastered such arts as the capturing of elephants and the hewing of implements from their thigh-bones, although their skulls presented a mosaic of characters in which anthropoid and human features were blended. In the sixth lecture Sir Arthur Keith, dealing with South Africa in prehistoric

times, said that Africa south of the equator had recently begun to rival Europe as the scene of prehistoric discovery. Along the coast of Cape Colony were many kitchen middens of large size, made by the Strandloppers, an extinct race allied to the Hottentots. Near these were ancient graves and caves which had been inhabited by man in early times; only a few had yet been explored, but it was now certain that the valley and banks of the Zambesi and of the Orange River had been inhabited by man in remote times. A sequence of forms could be recognized in the stone implements which broadly corresponded to those of Europe. It was possible that the inhabitants of both continents had borrowed a common inspiration from an earlier source. South Africa had been one of the most prolific of the gardens of Eden, producing such strange types as Bushmen and Hottentots, ancient peoples now rapidly approaching extinction. These were, however, special negroid developments, and they were no more and no less akin to the ape than were the Caucasians. Indeed, many of the extinct Strandloppers had large skulls and big brains. Two fossil skulls of large size had been found—one at Boskop in 1913 and one in a cave of Cape Colony in 1921, in strata which placed them about 15,000 years ago. The Sahara had been a very ancient barrier. As the ice sheet had spread southwards in Europe, the fertile belt spread southwards in the Sahara and narrowed the barrier, but never obliterated it. There had always been a clash of races in South Africa, and when the Dutch landed at the Cape three centuries ago the Zulu and Matbele types were extending southwards and exterminating the pastoral Hottentots, as these in turn had exterminated their cousins, the Strandloppers. In the seventh lecture, on recent discoveries of fossil ape and man in Africa, the lecturer dealt specially with the Taungs skull, discovered last year near Kimberley. Rhodesian man was clearly, he said, a cousin of Neanderthal man. Taking all the evidence into account, the African type was older and in every respect more primitive, more like the ape, than the Neanderthal. Whatever his geological age might prove to be, he represented a stage which we expected our ancestry to have reached at the opening stage of the Pleistocene period, at least 100,000 years ago. In facial feature the Rhodesian man was more like the gorilla than any other known species of man. Indeed in the width, prominence, and strength of his supraorbital ridges he outdid the male gorilla, but his canine teeth were not prominent as in the anthropoid, and his jaws were human in shape though ultra-human in dimensions. The fact that his teeth had suffered from caries led to the supposition that Rhodesian man had already discovered the uses of fire and the art of cooking. The characters of the Taungs skull discovered at the end of last year in a block of limestone corresponded to the stage reached by a child in the sixth year and by a chimpanzee at the beginning of the fourth; and the lecturer agreed with the opinion expressed by Professor Arthur Robinson that the skull was that of a young anthropoid ape, although of an extinct kind. In the size of the brain the Taungs animal was altogether anthropoid, while the jaws and face were essentially those of a young chimpanzee.

#### INDUSTRIAL EFFICIENCY.

A letter has been sent to the Scottish newspapers by the Lord Provosts of Edinburgh, Glasgow, Dundee, and Aberdeen, by the medical officers of health of these cities, and by the officials of the Industrial Educational Council, upon the subject of sickness and diseases of an occupational nature which lead to inefficiency. The communication deals with the work of the Industrial Educational Council, which is intended to give intensive and effective information in regard to the conditions of healthy living and the methods by which these may be obtained under varying conditions. Workers are to be approached through their own organizations, and this has been made possible by a recommendation of the Scottish Trades Union Congress Council to its branches to avail themselves of the health talks which are open to members of trade unions, and to all engaged in particular industries. A large number of meetings have been attended by workers and their wives. It is reckoned that at least 2,000,000 weeks' work is lost annually in Scotland through

sickness and disablement among insured workers, and that 50 per cent. of this would have been avoided if the workers had had the necessary knowledge. These health talks have been given to miners, bakers, printers, foundry workers, railway men, clerks, administrative workers, granite workers, steel workers, building trade workers, textile workers, etc., and in each case the workers' organizations have paid part of the expenses. During the period from October, 1925, to March, 1926, it is hoped to organize 200 health talks in Scotland. The council is composed chiefly of medical men, who have readily responded by giving their services without remuneration. To cover a five years' programme, however, £10,000 is needed, towards which about £700 has been received and spent on work already being carried out. If funds permit, it is desired to issue to the workers printed information on the subjects dealt with, and an appeal is made for subscriptions, which may be sent to the Secretary, Mr. J. Mackenzie, 21, Waterloo Place, Edinburgh, to whom also applications may be made for the health talks.

## Ireland.

### HEALTH INSURANCE AND MEDICAL SERVICES.

#### *Interim Report of the Committee.*

THE Committee of Inquiry into Health Insurance and Medical Services has submitted an interim report embodying the results of the investigations it has made up to the present time.

The Committee sets out under seven heads the main defects alleged against the case made in respect of each of them by the witnesses examined, of whom the Committee states there were forty-nine, representatives of the different interests concerned:

"(1) Owing to its association with Poor Law administration a persistent prejudice exists against the dispensary system.

"(2) The absence of a statutory right to pension occasioned the abuse of medical officers clinging to office after their professional usefulness had ceased.

"(3) Grave abuses exist in some districts affecting injuriously the election of medical officers; bribery, direct and indirect; political pressure; undue influence of relatives.

"(4) Some of the dispensaries, especially the branch dispensaries, are unsuitable for the purposes they are intended to serve, and in some cases insufficiently equipped.

"(5) The salaries of dispensary medical officers, first fixed in the middle of the last century, remained almost unchanged up to the beginning of the present century in spite of greatly increased cost of living and of the longer course of education required in order to become a medical practitioner. In 1904 the average salary of a medical officer in Ireland was £109. There was a slight gradual increase during the following ten years, and in 1914 the average had become £130. The average salary in the Saorstát is now £251, a sum which does not show much, if any, advance as regards purchasing power on the salary paid in 1904. In many cases the salary cannot pay the necessary out-of-pocket expenses of travelling through a dispensary district. Candidates have in the main been induced to join the Dispensary Service, not by the remuneration offered as salary, but by the prospect of earning a livelihood in private practice in the district.

"(6) There have always been great inequalities in the amount of salaries paid to medical officers in different areas. Moreover, the lower salaries prevail in those areas where the prospects of private practice are least. Although the Dispensary Service has always contained many medical officers of skill and devotion, it has never been attractive to the more ambitious of young Irish doctors; as a consequence not a few have been compelled to go abroad.

"(7) There is no arrangement in the Dispensary Service to provide medical officers with the opportunity of refreshing and increasing their knowledge by attendance on courses of study at recognized centres. As medical and surgical knowledge are advancing rapidly, it becomes increasingly necessary to give medical officers opportunity for such further study.

"The Committee gave serious consideration to these alleged defects in the medical services comprised in the Medical Charities Act. In our view the evidence in support of (1) was given by persons lacking knowledge of the working of the Dispensary Medical Service in counties where the development of the administration has proceeded according to the policy of the Department of Local Government and Public Health. The witnesses for the most part relied on their experience in the city of Dublin or in places where county administration is too recent to be yet effective or on experience of the system prior to the amalgamation of unions. We consider that the unification of the dispensary and hospital service under special county

committees will, when such schemes have had time to develop, remove the former prejudice. This system of committees, distinct from county homes and home assistance committees, should be extended to every county in the Saorstát. As regards (2) a fixed retiring age is not necessary. The right to pension under Section 8 of the Local Government Act, 1919, has enabled medical officers to retire before their functions are impaired by old age, and has, it would appear, practically put a stop to the abuse complained of. The Local Government Bill (1924) now awaiting the decision of the Seanad is framed to regulate further the pensioning of medical officers. In respect of (3) many witnesses stated that they would prefer to transfer the power of selecting medical men for public appointments to a central authority; the witness representing the County Councils General Council advocated this as a necessary reform while awaiting the setting up of a State medical service. With a view to eliminating the taint of corruption and inefficient modes of appointment, selection committees, consisting of independent professional experts and selected public representatives, have been tried as an expedient, with so far not unsatisfactory results. In our opinion such medical appointments for the present should be made by special tribunals under the aegis of the Civil Service Commission; thus, as the circumstances of particular appointments may require, the test to be applied might be (a) examination alone, (b) examination supplemented by consideration of experience and general fitness, and (c) in some cases selection without the formal test of an examination. In (4) there is much substance. Undoubtedly many dispensary buildings are unsuitable. The practice of granting advances out of the Local Loans Fund for the provision of new buildings under the Dispensary Houses (Ireland) Act was, unfortunately, discontinued under the restriction of borrowing during the world war. Where unsuitable accommodation is now provided the local authorities should be required to remedy the defects. As regards (5) and (6) we accept the case made in the first paragraph of (5). The Department of Local Government and Public Health, particularly in the last few years, has used its influence to improve the remuneration of the dispensary medical officers. In twenty county areas scales of salaries are now regulated and revised so as to be on a uniform basis within each county area. The problem has yet to be dealt with in ten county areas. The adjustment of the medical officers' salaries in Roscommon, Longford, Leitrim, Cavan, and Mayo was deferred owing to economic and other reasons. In Cork the amalgamation of unions is of too recent date to permit the actual operation of a scheme. The increase of salary shown by the average figure for the year ended March 31st, 1924, upon the figure admitted to have been grossly inadequate in 1904 is, however, more apparent than real owing to the increased cost of living. We hope to deal more fully with the matter in our final report. The Committee approves the suggestion in (7), and recommends that 'study leave' for a period not less than three months should be granted at least as often as once in every five years, and that evidence of having taken advantage of such opportunities should receive consideration where promotion is in question. During 'study leave' the medical officer should, subject to regulations, receive full salary without deduction for payment of a locum tenens; a grant might be provided to cover fees for study. The Department of Local Government and Public Health has already, within the limits of its powers, granted facilities of the kind to medical officers. There is, however, no legal authorization for paying a locum tenens during the period of absence."

#### ULSTER MEDICAL SOCIETY.

The annual meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on May 14th, when the President, Dr. Singleton Darling of Lurgan, was in the chair. The reports of the council, of the librarian, and of the treasurer, which showed a credit balance of £170, were read and passed. On the proposal of Professor Thomson, seconded by Dr. McKisack, a hearty vote of thanks was passed to Dr. Marshall on relinquishing office as honorary secretary. The following office-bearers were elected:—*President*: James A. Craig, M.B., F.R.C.S.Eng. (Belfast). *Ex-President*: J. Singleton Darling, B.A., M.D. (Lurgan). *Vice-Presidents*: W. Burns, L.R.C.P.S. Ed., D.P.H.; Thomas Killen, M.B., F.R.C.S.Eng. (Larne). *Council*: A. Dempsey, M.B., B.Ch.; G. G. Lyttle, M.B., B.S., M.R.C.S., L.R.C.P.; Professor R. J. Johnstone, M.B., F.R.C.S.Eng., M.P.; H. P. Malcolm, M.C., M.Ch.; R. Marshall, M.D., F.R.C.P.I.; P. O'Flaherty, M.B., B.Ch. *Honorary Treasurer*: T. T. Lewis, M.D., B.Sc. *Honorary Librarian*: W. L. Storey, B.A., M.D. *Honorary Secretary*: R. Maitland Beath, M.B., B.S. *Editing Secretary*: J. A. Smyth, M.D., B.Sc.

## England and Wales.

### ULTRA-VIOLET LIGHT INSTALLATION AT BATH.

THE new ultra-violet rays department at the Royal Baths, Bath, was formally opened on the afternoon of Saturday, May 16th, by the Mayor of Bath, Alderman Cedric Chivers. The company included the Chairman (Councillor C. H. Haeker) and other members of the Baths Committee; Mr. John Hatton, director of the Baths; Alderman Preston King, M.D.; Dr. F. G. Thomson, President-elect of the British Medical Association; Dr. J. F. Blackett, medical officer of health for the city; and many other members of the local medical profession. The principal guest was Dr. Leonard Hill, F.R.S., director of the Department of Applied Physiology and Hygiene at the National Institute for Medical Research at Hampstead, who gave an address on ultra-violet rays and their application. After a brief reference to the knowledge of the curative effect of sunshine in ancient and mediæval times, he spoke of the injurious effects upon health of the sedentary indoor lives led by the overclothed inhabitants of modern cities. He then explained briefly the difference between the active invisible rays beyond the violet end of the spectrum and the dark heat rays beyond the red end. The action of the former on the skin depended, he said, first, on penetration, and secondly, on absorption, and he indicated the effects of ultra-violet rays of different wave-lengths. The intensity of any source of ultra-violet radiation could be measured by means of a solution of 30 per cent. acetone coloured with methylene blue. Discussing the therapeutics of artificial sunlight, Dr. Hill spoke of the remarkable benefit, especially in children, of arc-light lamps in chronic infections of obscure origin. He was sure the bathing establishment at Bath would find the new installation a most valuable adjunct to its treatment of many cases, particularly in winter. At the conclusion of the address questions were asked by medical members of the audience, mainly regarding the details of treatment. Dr. F. G. Thomson, in seconding a vote of thanks to Dr. Leonard Hill, said he had been extremely impressed by two things: one was the value of ultra-violet light therapy, and the other was that this was a form of treatment which must not be used lightly, but needed very careful, serious study by those proposing to use it. Obviously, a new form of treatment such as this was open to very serious abuse unless great care were exercised. After the opening ceremony many of the visitors inspected the new department, where a demonstration of the treatment had been arranged.

### CRIPPLING DUE TO FRACTURES.

The delivery of the lecture on "Crippling due to fractures: its prevention and remedy," given before the University of Liverpool by Sir Robert Jones on the afternoon of Tuesday, May 12th, and printed as the opening paper of our last issue (p. 909), was not attended by much formality. The vice-chancellor, Dr. Adam, briefly stated the circumstances attending the foundation of the Lady Jones Lectureship. Mr. J. Rankin gave £2,500 in memory of Sir Robert Jones's wife in 1918. By the addition of annual interest the sum had been increased, and it was decided to devote the proceeds to the institution of a research scholarship in orthopaedics and of a biennial lecture on the subject. Sir Robert Jones's plea for better organized teaching and for the more systematic treatment of fractures was followed with great attention by a large audience, which seemed to agree with his thesis—that as insufficient treatment and neglect might transform a simple fracture into a chronic deformity, it was not open to the teaching hospitals and other large hospitals to shirk the responsibility of establishing a system for the adequate treatment from the first of fractures of the limbs. There can be no doubt that great numbers of adult cripples are manufactured by want of continuous efficient treatment from the time of the injury, and that the medical student has not, as a rule, sufficient opportunity for learning what are the best modern methods available.

## France.

[FROM OUR OWN CORRESPONDENT.]

### The Working of the Insurance Act.

PROFESSOR SERGENT has recently pointed out to the Academy of Medicine that the provision of the law relating to medical insurance which gives all sick persons the free choice of doctor will have some curious effects on the administration of Paris hospitals. There is nothing, he said, to prevent an in-patient from enlisting in any doctor he may select out of the 5,000 practising in Paris. It might even happen that forty patients in one ward would be separately treated by different doctors, each one employing his own pet method. In this way anarchy would be produced, hospital administration would pass out of the hands of the Assistance Publique into those of the insurance societies, and there would be no guarantee of medical efficiency. The beautiful theory of democracy which maintains that any man is as good as any other would be applied to the medical profession; doctors would all be assumed to be equally competent, and obviously the instruction of students would lose much. In fact, we should return to a system of classes devoted entirely to didactic lectures, and the old system of beginning the clinical teaching of the student at the bedside would come to an end. This would mean that clinical demonstrations in the theatre would replace that study of teacher and taught in common which has been the charm of our system and the secret of the strength of the French medical school. *Dii talem arctite casum!*

### Public Health and the Budget.

Before the same learned body Professor Bernard attacked the recent decision of Parliament to withdraw on the score of economy a sum of 132 million francs from the public health estimates. Since the war great efforts have been made to deal with preventable diseases, and the results are already striking. The economic value of public health, however, is not obvious to the public eye: statistics make no appeal to the imagination. To grudge money for the fight against disease would have a ruinous effect on the country in two ways—by loss of men and loss of money, for the result on the expenditure on institutional treatment for incurables, the loss of working capacity, and waste of all kinds, would be terrible. It is calculated that if the State would devote 20 million francs a year to the fight against syphilis alone it would save thousands of millions. While England was spending 567 francs per thousand people in this branch of prophylaxis France only spent 77 francs. The Department of the Seine alone treated in hospital 1,890 general paralytics at an annual cost of 9 million francs. To this is to be added the cost of the treatment of the insane and of those suffering from diseases of the spinal cord. Reductions in the public health estimates reveal themselves in heavy charges on the State later on. Alas! the opinion of the Academy of Medicine weighs very little in the parliamentary scales.

### British Surgeons in Paris.

Last month a party of British surgeons, some twenty in number, visited the chief surgical clinics of Paris. The party, members of the Chirurgical Club, consisting of surgeons from the extra-metropolitan medical schools of England and Scotland, was led by Professor Marnoch of Aberdeen. The party witnessed operations performed at different hospitals each morning. They were particularly interested in a demonstration of the radiographic diagnosis of gall stones in the clinic of Professor Duval at the Hôpital de Vaugirard, and in the skiagrams of the gall bladder obtained after an intravenous injection of an iodine salt, in the clinic of Professor Gussot at the Salpêtrière Hospital. Visits were also paid to the Radium Institute founded by Madame Curie, and to the Pasteur Institute, where the tomb of Pasteur was specially opened for their inspection.

### International Society of Medical Hydrology.

At the International Society of Medical Hydrology, which held its first meeting in Paris on April 20th, no fewer than

eight countries were represented. The society was founded in London in 1922, and is now flourishing. The meeting discussed the question of the treatment of diabetes by insulin from the hydrological point of view, and also the treatment of rheumatic exudations following trauma. A dinner, presided over by Professor Carnot, was attended by representatives of the Institut d'Hydrologie, the Collège de France, and the French Government. On the following days demonstrations were given at the Sorbonne by Professor Urbain; at the Faculté de Médecine by Professor Desgrez; and at the Collège de France by Professor Lepape. Hydrology is at last being recognized in France as a specialized science and an important part of therapeutics. It is curious to reflect that the first kind of treatment used in the history of mankind should be the last to be taught in our modern medical schools.

G. MONOD.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week read the Widows', Orphans', and Old Age Pensions Bill a second time by 401 to 125, and has sent it to a Committee of the whole House. Other business has included a debate on the Ministry of Transport Vote, and an effort was made to get the Poor Law Emergency Continuation (Scotland) Bill through its remaining stages. Debate on the Finance Bill will commence next week.

The Medical Committee met on May 18th, when Mr. W. G. Spencer addressed it on the supply of cadavers for anatomy and operative surgery, remarking incidentally that boards of guardians were more willing to supply subjects for the second purpose. He did not suggest special legislation, but that the Committee should see whether it could help to reduce present difficulties in ensuring a supply of subjects for dissection. The Committee next discussed small-pox and vaccination, exploring the present position and the possibilities of further action, including introduction of a private bill to focus public opinion.

In view of the unsatisfactory reply given by the India Office to Sir Richard Luce's question, the Committee discussed the unsatisfactory conditions at present existing, and agreed to continue to press the Government for an early change in them. The Committee considered also the amendment, in regard to the supply of insulin, which Dr. Shiels had moved to the Public Health (Scotland) Bill; it was suggested some compromise should be effected between the terms of the bill which did not enjoin any method of supply and Dr. Shiels's proposal that insulin should be supplied only by chemists. The general feeling of the Committee was that insulin should be supplied either through a chemist or a doctor.

The Committee decided that it could not support a proposed petition to the Prime Minister in favour of allowing former mental patients to give evidence in public before the Lunacy Commission.

An invitation was received from M. Spahlinger for the Medical Committee to visit his research station in Switzerland. The Committee decided that it would be well if some of its members could go to Switzerland for the purpose, but that it could not, as a body, accept the invitation unless and until it had received a report from any such members.

### The Pensions Bill.

The second reading of the Widows', Orphans', and Old Age Contributory Pensions Bill was moved by the Minister of Health on May 18th. He explained that the scheme was linked up with health insurance, chiefly for the reason that the latter covered so much wider a field than unemployment insurance, including something like 15,000,000 workers against 12,000,000. The Government proposed to invite the assistance of the approved societies in providing certificates of the insured by virtue of which a man would become entitled to benefits under the bill, but the pensions would be paid through the Post Office. Under the National Health Insurance Act an insured person at 70 was entitled to free medical benefit for the rest of his life. But, if he had only reached 65, and ceased to be employable and passed out of insurance, then he lost the right to medical benefit. That had been a considerable grievance, which the provisions of the bill amended. The third schedule of the bill provided that in future insured persons who reached 65 would have this boon of medical benefit for the rest of their lives.

The grounds of the opposition to the bill by the Labour party were stated by Mr. Wheatley, the ex-Minister of Health,

who moved its rejection on the ground that it was a contributory system and provided allowances which were inadequate.

Mr. Lloyd George asked whether it was not possible to have another benefit. The bill did not cover all accidents against which the industrial population had to insure. Before the Health Insurance Act there were two capital charges of which the working classes had always been frightened, one of which was the doctor's bill after a prolonged illness. In the past that took years to wipe out, and the only contributor very often was the doctor himself. ("Hear, hear.") The doctors lost three-quarters of these bills in that respect, not because the workmen would not, but could not, pay. That difficulty had been disposed of by the Health Insurance Act. The other trouble was funeral expenses. There were 50,000,000 voluntary insurances to-day against payment of funeral expenses, and if there were a compulsory insurance for £10 per person it would be a great boon. He urged that the pension should not be awarded at 65, but on a disability basis.

The debate was resumed on May 19th, when Dr. Fremantle said that while in the meantime he supported this magnificent measure of social reform, he felt that money was being wasted by giving pensions rigidly to those who were 65 years of age. The Government actuary's tables were based on the life tables, but the mortality rates were diminishing, and were likely to go on diminishing for some time. In the course of the next forty years the number of people between 65 and 70 years of age would have nearly doubled. Not only had the expectation of life increased, but the length of working life had also been increased. The present pension scheme permanently threw people out of work at 65, but he was sure that in future the pension scheme ought to be on a disability basis. The decision, as in the case of war disabilities, would be by a medical board, diluted by such other elements as might be required.

#### *Proposed Coroners Bill.*

In the House of Lords, on May 19th, Lord Darling called attention to the not infrequent practice of coroners' courts holding inquests simultaneously with the hearing by justices of charges against persons arrested and accused of murder or manslaughter of the deceased person. He suggested that if at any inquest the coroner was informed, before the jury had given their verdict, that some persons had been so charged, then it should be the duty of the coroner, in the absence of good reason to the contrary, to adjourn the inquest. The Lord Chancellor, in reply, agreed that a certain amount of mischief resulted at present in these cases, and as a witness of the tragedy might have to give evidence four times great expense was involved, while the case of the deceased man was sometimes prejudicial. The Government proposed to introduce a bill dealing with the whole law of coroners and a number of other matters which had arisen in connexion with inquests. The bill would contain a clause much to the effect suggested by Lord Darling. The bill was ready, and was only awaiting the approval of some local authorities to some financial matters. He hoped that within a short time it would be introduced and passed into law.

#### *The Distribution of Insulin.*

During the debate on the Public Health (Scotland) Bill in the Standing Committee on Scottish Bills, an amendment was moved by Dr. Shields to provide that medicines for the treatment of diabetes under the bill should be supplied (a) by chemists and druggists, and dispensed either by or under the direct supervision of a registered pharmacist; or (b) through a registered pharmacist in the employment of the local authority, except that, where circumstances made it necessary, the supply might be obtained from a medical practitioner. Dr. Shields said there was a suggestion that because it was made up in a form already complete and standardized and did not require compounding, it was unnecessary for a specially qualified person to be concerned in its distribution. That struck at the root of the Pharmacy Acts. Insulin was already supplied under the National Health Insurance Acts, which provided that it must be supplied under the supervision of a qualified pharmacist. Insulin was also supplied by Poor Law authorities, and there again its distribution was supervised by qualified persons. Under the present bill the public health committees of county and borough councils would probably have the distribution of insulin. Large authorities already had properly qualified pharmacists in their employment, and in other cases the patients were treated by their own doctors, who would supply insulin paid for by the local authorities. With these cases the amendment did not propose to interfere. Insulin was injected hypodermically, and a practice had necessarily grown up whereby patients were instructed in the hospitals before they left as to the method of injecting insulin for themselves. That was now quite a general practice, and it was one which such patients used specially to deal with. The insulin person. The bill was only a beginning of a much wider application of the same principle of the supply of drugs to the public. The executive of the Pharmaceutical Society urged that the amendment should be adopted.

The Secretary for Scotland (Sir John Gilmour) said that it would be dangerous to admit that the issue of insulin should be confined in present circumstances to chemists. The actual preparation should be conducted by those qualified to do it, but the

Scottish Board of Health, working with the Ministry of Health in England, had been able to obtain insulin in bulk more cheaply than the ordinary chemist could retail it. This was a fresh departure and undoubtedly one of the greatest importance. The department had been able to obtain insulin at something like 2s., as against 2s. 8d. by the other method. The treatment must originate either in a hospital, or in a clinic, or under direct medical supervision. There had crept into Dr. Shields's speech some idea that chemists were going to advise and to supervise the use of the drug. That would not be the province of the chemist. The Government must resist the amendment.

The amendment was then negatived without a division and the bill was reported to the House.

*Medical Services in India: Pay and Allowances.*—Sir Richard Luce asked Earl Winterton, Under Secretary for India, on May 18th, if the married officers of the Royal Army Medical Corps, the Royal Army Veterinary Corps, and the Army Dental Corps, serving in India, were still excluded from the increased pay and allowances, including quarters, recently granted to other branches of the British Army, by which exclusion a major of the Royal Army Medical Corps received 75 rupees a month less than a senior captain of the Royal Engineers, and 5 rupees less than a captain of the Royal Army Service Corps; and if he would assure the House that members of these three services would not eventually suffer by reason of the delay involved in the consideration of their case. Earl Winterton replied that the case of the services mentioned had been reserved for separate consideration in view of the possibility of changes affecting them in the near future. If the examination of the cases revealed sufficient grounds, increases would be given from the date which might be appropriate. Dr. Fremantle asked if His Majesty's Government would take steps to accelerate this matter in order to get some officers for the examination to be held in July. Lord Winterton was understood to reply that that matter did not depend on the India Office or on the Secretary for India, but on the Government of India. The considerations he had mentioned had reference to the possibility of a change affecting the home services, and until that was settled it would be difficult to come to a decision in the other case.

*The Medical Acts.*—In reply to Mr. Basil Peto, the Minister of Health said his attention had been called "to the action of the General Medical Council under the powers conferred on them by Section 29 of the Medical Act, 1858, in causing to be struck off the Register the name of a doctor on the ground that he was guilty of infamous conduct in administering anaesthetics to a patient of a manipulative surgeon not possessing a degree qualifying him to practise in medicine or surgery." Mr. Peto further asked whether Mr. Chamberlain would consider the need of amending the Medical Act in order to give the same right of appeal against decisions under Section 29 of the Medical Act to the Privy Council which is given in the Act under Sections 23 and 24. Mr. Chamberlain replied that the sections of the Medical Act, 1858, which Mr. Peto mentioned gave no right of appeal by individuals to the Privy Council. Mr. Peto then asked the Minister of Health whether he was aware that the subject of manipulative surgery, with one or two exceptions, was not taught in British medical schools; whether he would take steps to point out the advisability of rectifying this omission to the General Medical Council and other responsible bodies; and whether, in the event of a refusal by those bodies to recognize the value of these therapeutic measures, he would take action to insist upon this subject being given adequate prominence in the medical curriculum. Mr. Chamberlain replied that the revised medical curriculum adopted by the General Medical Council in 1922, which came into force on January 1st, 1923, included practical instruction in surgical methods such as massage and manipulation, and in electro-therapeutics and in the other action suggested in the representation. Mr. Peto asked whether persons skilled in manipulative surgery had not to be qualified surgeons under the Medical Act before they were allowed to give the instruction under the revised curriculum. Mr. Chamberlain asked for notice of this. Dr. Watts asked whether Mr. Chamberlain was aware that manipulative surgery was pure humbug. No answer was returned.

*X Rays for Insurance Patients.*—In reply to questions as to the provision of facilities for x-ray examination as one of the benefits under the National Health Insurance Act, the Minister of Health said that payment for an x-ray examination could at present be made under the National Health Insurance Act only where the examination was incidental to a service, such as dental or hospital treatment, made available under an approved society's scheme of additional benefits. The Royal Commission on Health Insurance was now considering the extension or development of benefits under the Health Insurance Act, and the suggestion made by Mr. Peto would be forwarded to the Commission. Mr. Neville Chamberlain also announced that he was referring to the Royal Commission on Health Insurance, for consideration, the question of granting exemption from health insurance payments of those workers already covered by payment to superannuation and provident funds at a condition of their employment.

*Vaccination of Workhouse Inmates.*—In reply to a question as to the vaccination of inmates of Chesterfield Workhouse, as to several deaths reported to have been accelerated if not so caused, and as to an inquiry to be held by the guardians, Sir Kingsley Wood said the Minister of Health was informed that, on the occurrence of a case of small-pox in a ward occupied by elderly females, 379 of the inmates of the institution, including elderly

persons, were offered and accepted vaccination. Forty-eight of the inmates were not vaccinated, either because this was thought to be undesirable on account of their state of health or because they declined. Since the vaccination was carried out there had been no death in the institution which could be attributed to, or was accelerated by, vaccination. The vaccinations were carried out on the advice of the medical officer of health of the borough, acting within his routine and prescribed duties. The Minister did not think it was necessary for an inspector of the Ministry to attend the guardians' inquiry, but he had asked for a report of it.

**Magistrates and Objectors to Vaccination.**—On May 18th Mr. Groves asked the Home Secretary if his attention had been called to the refusal of certain magistrates to witness statutory declarations under the Vaccination Acts; and if he would follow the precedent of one of his predecessors and circularize all magistrates, calling their attention to their legal obligations to witness statutory declarations when sitting in open court, expressly pointing out to them that they were neither required nor authorized to cross-examine applicants as to the reasons for their objections, but that their conscientious objections were sufficient. Mr. G. Locker-Lampson, Under Secretary to the Home Office, in reply, said that on March 17th Mr. Chamberlain had received a deputation from the National Anti-Vaccination League, which made representations to him on the subject. After carefully considering the particulars submitted by the league, he came to the conclusion that no case had been made out for the issue of a circular to justices.

**Cancer.**—The Parliamentary Secretary to the Ministry of Health (Sir Kingsley Wood) informed Mr. Groves that the inquiries with regard to cancer which certain local authorities were carrying out on the advice of the Departmental Committee on Cancer had not reached a stage when a definite statement on progress could usefully be made. The Departmental Committee was continuing its investigations, and circulars were issued by the Ministry of Health to local authorities giving information on cancer which might be helpful.

**A Lumbar Abscess.**—On May 18th Mr. Hardie asked the Minister of Pensions to grant a special medical inquiry into the case of an ex-service man who was suffering from the presence of shrapnel in his body, although at his final appeal in April he was disallowed on the ground of his disability being non-attributable to service. Lieut.-Colonel G. F. Stanley, Parliamentary Secretary to the Ministry of Pensions, replied that the man's claim was in respect of a lumbar abscess, and the decision both of the Ministry and of the appeal tribunal was reached after full consideration of medical evidence obtained from hospitals and otherwise as to the causation of the condition. There was no ground for granting a special medical inquiry. Mr. Hardie asked whether the x-ray plate taken at Stobhill Hospital, Springburn, Glasgow, would be produced as evidence whether there were parts of shrapnel in the man's body. Colonel Stanley said that the claim was not in respect of parts of shrapnel in the man's body. An x-ray plate was produced before the tribunal, and it was clear from it that the shrapnel had nothing to do with the abscess. All the man had been claiming for was the abscess. The medical board decided that this was not due to the wound he had received. He went to the appeal tribunal, which decided to have a report from the hospital and an x-ray photograph in order to make sure that this was not the result of the wound, and they confirmed the decision of the medical board. Mr. Hardie announced that he proposed to raise the subject in the House.

**Secret Remedies.**—On May 19th Colonel Day asked the Minister of Health whether his attention had been drawn to the dangers arising from the unrestricted sales of certain patent medicines, where the manufacturers were not compelled to state the composition of the products bearing their labels; whether he proposed to take any action in the matter to protect the public further; and if he would introduce legislation to compel all manufacturers of patent medicines to state plainly on the labels of medicines sold the ingredients contained in them. Sir Kingsley Wood replied that the Minister appreciated the importance, in the interest of public health, of securing some statutory regulation of the conditions under which patent medicines were advertised and sold, but in the present state of business he did not anticipate that it would be possible to introduce legislation on this subject during the present session. Colonel Day asked whether Sir Kingsley Wood was aware that many of these patent medicines contained injurious ingredients, and that the public took them a little too freely, not knowing what they contained. Sir Kingsley Wood said that might be so, but the difficulty was to find time for legislation. Mr. W. Thorne asked if Sir Kingsley Wood had ever been in the market places on a Saturday night and listened to the persons who sold these medicines, and seen how easily people could be "chloroformed" in this direction. Sir Kingsley Wood: And in other directions, too.

**Opium in Assam.**—Earl Winterton, replying, on May 18th, to Mr. Lansbury, said that in 1923-24 the proportion of Assam revenues derived from opium (licence fees and profit on sale proceeds) was about 18 per cent. (gross). The provincial Government had taken steps to reduce consumption; a system of registration had been introduced, and an experiment was being made with rationing. The amount of opium issued had fallen by nearly 50 per cent. in the five years from 1919-20 to 1923-24. The Government of India had recently addressed inquiries to local Governments regarding the high rates of consumption of opium in some areas. The Secretary of State proposed to await the result of these inquiries.

**Schools for Physically Defective Children.**—In reply to a question by Sir Henry Craik, the Minister of Education said that forty-eight local education authorities had provided schools for physically defective children. Of these schools, 113 were day and 37 resi-

dential schools. One day school and 71 residential schools of this type were provided by voluntary bodies. Out of 318 local education authorities only 7 had not provided school clinics for treatment of physically defective children, and 5 of the 7 had submitted proposals. In reply to another question the Minister said that last year 567 blind children, including 287 partially blind, and 4,301 crippled children, other than those suffering from active non-pulmonary tuberculosis, were attending no recognized school or institution. Many of the crippled children did not need to attend special schools, but rather required orthopaedic treatment to enable them to continue in attendance at ordinary public elementary schools, and he was encouraging the development of such treatment. He had already asked all education authorities to give careful attention to special school accommodation for blind and crippled children.

**Butter and Margarine.**—In answer to a question as to the discontinuance of the supply of butter by the Metropolitan Asylums Board, the Minister of Health said that he was advised that the use of margarine was quite compatible with a good diet, provided that the other constituents of the diet were satisfactory. The dietary adopted by the Metropolitan Asylums Board fulfilled this condition and, further, made adequate provision for adjusting the diet to suit any particular case. He was not prepared to recommend that the allowance of butter be continued irrespective of season. The provision for adjusting the diet to the needs of children was adequate.

**"Headache Powders."**—In reply to Colonel Day, the Minister of Health said he was informed that antipyrin was an ingredient in certain proprietary headache powders, but he had no information that its use was increasing. As in the case of acetanilide (see JOURNAL, May 16th, p. 944), he doubted whether, pending legislation for the control of secret remedies, the sale of headache powders containing this drug could be effectively restricted.

**Infants' Foods.**—Mr. Groves, on May 19th, asked the Minister of Health whether he would consider the possible danger to infant life arising from the sale of proprietary infant foods consisting largely of starch, and introduce regulations governing the sale of such foods, in view of the fact that he had issued instructions controlling the sale of dried milks. Sir Kingsley Wood replied that the Minister of Health was sure that misleading claims were sometimes made as to the value of infants' foods, consisting largely of starch, but he was not satisfied, on the information at present before him, that there was sufficient evidence of danger arising to public health to justify the issue of regulations at the present time. Mr. B. Smith asked whether the Minister would circulate through the medical side of the Ministry the names of the firms who largely embodied starch in so-called foods. Sir Kingsley Wood said he did not see the necessity for that. The consumption of these proprietary foods was decreasing. If sufficient evidence of danger was obtained the Minister would take immediate action.

**Infectious Hospitals: Poor Law Medical Relief.**—The Minister of Health informed Mr. Webb that there are about 1,100 hospitals, with 44,000 beds, in England and Wales for treatment of infectious diseases, including tuberculosis. No information is available as to the total medical and nursing staffs of these hospitals, nor as to the number of patients treated. In 1922-23 the cost to the rates of this service was £3,631,000. In January, 1921, there were 1,123 indoor posts for Poor Law medical officers and 3,558 outdoor posts. Information as to salaries paid was not available. In March, 1921, 17,405 persons were receiving outdoor medical relief.

**Public Libraries and Infection.**—Answering Mr. Groves, on May 6th, Sir Kingsley Wood said the Minister of Health was advised that medical officers of health were fully alive to whatever danger of infection there might be to frequenters of public libraries through the use of books previously handled by persons suffering from infectious ailments. Section 59 of the Public Health Acts Amendment Act, 1907, made special provision for precautions to prevent the spread of infection through the use of library books, and that section could be put into force in any district on the application of the local authority. The Minister of Health did not consider it necessary to undertake any special investigation or to issue periodical instructions to local authorities on the matter.

#### Notes in Brief.

No State has yet ratified the agreement concluded by the first Opium Conference at Geneva. The British Government hopes to do so soon, but has first to consult certain Protectorates. The Convention concluded by the second Opium Conference remains open for signature till September 30th, and cannot be ratified before then.

The British Government is unable at present to ratify the International Convention on night haking.

Since December 31st 21 outbreaks of foot-and-mouth disease have occurred in Great Britain.

In 1924-25 health insurance benefits equal to 12s. a head were distributed in England and Wales, in addition to 6s. 8½d. a head for domiciliary Poor Law relief and 11s. 5½d. a head for old age pensions.

Attendances of children at school clinics or for other medical treatment rank as school attendances if made under approved arrangements.

Last year 528 children in the West Riding of Yorkshire were ascertained to be mentally defective within the meaning of the Education Act, 1921.

It is estimated that 421,000 boys and 416,000 girls reached the age of 16 during the year 1924.

The Minister of Education has refused to send out a recommendation that every medically fit child should be taught swimming.

The second reading of the Nursing Homes (Registration) Bill has been set down for June 19th, and the second reading of the Therapeutic Substances Bill for May 25th.

The India Office has received a report from the Government of India to the effect that no cruelty attaches to the export of monkeys from Bombay for medical or surgical purposes, and that no religious offence has as yet been given by the capture of the animals.

The Board of Education has made no conditions or regulations for the supply of ambulances serving the needs of schools for physically or mentally defective children.

## Correspondence.

### VOMITING IN INFANCY.

SIR,—I have read with very great pleasure and profit Dr. Cameron's Lumslean Lectures on some forms of vomiting in infancy, but I would venture to suggest that some of his remarks on hypertrophic pyloric stenosis are open to criticism. Dr. Cameron's thesis is that the cause of hypertrophic pyloric stenosis and pyloric spasm is an achalasia of the pyloric ring sphincter. He points out that in pyloric stenosis the hypertrophy involves a great deal more than the true pylorus—that is, the pyloric ring sphincter; indeed, he produces considerable evidence that the latter is not hypertrophied at all, and draws the deduction that the hypertrophy is the result of an endeavour to pass the contents of the stomach past the obstruction caused by the failure of the pyloric ring muscle to dilate.

The fact that hypertrophy is not limited to the ring sphincter is obvious and generally accepted. Thus Cunningham, in the paper quoted by Dr. Cameron, says: "In this disorder the whole length of the canal is involved." The word "pylorus" is used in these cases as a synonym for pyloric canal, which is unfortunate, because it only adds to the confusion that already surrounds the terminology of the pyloric portion of the stomach. The pyloric canal was labelled by His the "pyloric antrum," whereas, according to the B.N.A. nomenclature, the pyloric antrum includes the pyloric canal and the vestibule. Discussion would be simplified if, as suggested by Cunningham, the term "antrum" were discarded and Jonnesco's terms of "pyloric canal" and "pyloric vestibule" were used, and this terminology I use in this letter.

The circular musculature of the pyloric canal in infants is relatively thicker than in adults and the lumen always approximates to a canal in shape. In the foetus the pyloric canal is even more a canal than in the infant; the pyloric ring sphincter does not function as a valve, but closure occurs by the contraction of the circular musculature of the pyloric canal. In hypertrophic pyloric stenosis the whole circular musculature of the pyloric canal is hypertrophied and acts as a sphincter in a manner similar to that of the pyloric canal of the foetus; so similar, indeed, is it that Dent may well be forgiven if, in Dr. Cameron's words, "he may have mistaken the rigid and tightly contracted pyloric cylinder . . . normal in the foetus for the pathological condition with which he was familiar." The essential factor in pyloric stenosis is the condition of the circular coat of the pyloric canal, and not the condition of the ring sphincter, whereas in pylorospasm the converse is the case.

Dr. Cameron also maintains that "there is no true stenosis present." If by "no true stenosis" he means that there is not complete stenosis, I agree; but I submit there is clinical evidence in favour of the existence of a relative stenosis, which is converted into a complete one by spasm or abnormal growth of the circular musculature of the pyloric canal imprisoning the mucous membrane, or by swelling of the mucous membrane, or by a combination of these factors. Sauer has recently produced anatomical evidence of this relative stenosis. He made, by the reconstruction method, wax models of the pylori of two infants of the same sex, approximately the same birth weight, and

practically the same age at the time of death, and found that the lumen of the pyloric canal in the stenosis case was the same at the stomach end, was larger at the duodenal end, but narrower in the middle, than the canal in the normal child.

Whether the state of the pyloric ring sphincter in pyloric stenosis be that of achalasia or spasm is not, I think, of great importance if it be remembered that the essential thing is the condition of the circular musculature of the pyloric canal. For myself, I believe that it is spasm and not achalasia, for if the condition were one of achalasia I cannot understand the beneficial effects of stomach wash-outs, the relaxation of the pylorus shortly before death in some cases, as evidenced by the occurrence of terminal diarrhoea and by x-ray examination, and the inability of pressure over the stomach or sodium bicarbonate to force the passage of the pylorus.

In Dr. Cameron's view it is a mistake to regard pyloric stenosis as congenital in origin, and he cites as evidence against the congenital origin the fact that many cases do not show symptoms until from two to four weeks after birth. I have already suggested an explanation of the late onset of the symptoms, but I think that sometimes too much is made of this point; thus, out of 448 cases collected by Sauer, in 103 and 125 cases respectively the onset of vomiting occurred in the second and third weeks, but in 105 cases the onset of vomiting occurred in the first week; and instances in which a history of vomiting since birth is obtained are surely not unknown in the experience of those physicians who see a large number of these cases. Now any theory which explains the disease must explain all cases, even those which show symptoms directly after birth. I would like to ask Dr. Cameron how, on his thesis, he explains the great degree of hypertrophy which he must have met with in cases which were operated on when three weeks old. I cannot imagine such a degree of hypertrophy developing in so short a space of time if the condition be a post-natal one, and I would also submit that additional evidence in favour of a congenital origin is found in the similarity of the hypertrophic pylorus to the foetal pylorus which I have already mentioned, and also in Professor J. C. Brush's investigations into the development of the musculature of the pylorus, which are recorded in my Goulstonian Lectures (1923).

Of one of the x-ray photographs illustrating the lecture, the lecturer says: "I believe that in this photograph, which has caught the contractile cylinder in a phase of relaxation, we have outlined the enormous lumen which, after death, is completely obliterated." Surely there is some mistake here, since the only part of the stomach the lumen of which is completely obliterated after death is the hypertrophied pylorus (pyloric canal), and I cannot think that Dr. Cameron would suggest that the pyloric canal can ever dilate to this degree. If such dilatation did in fact ever occur it surely would have been observed at operation. Earlier in this lecture the contractile cylinder is defined as consisting of "pyloric antrum" and "vestibule"; if in the above quotation by "contractile cylinder" is meant the pyloric vestibule only, then I maintain that after death the lumen is not obliterated. The explanation of the photograph is, I submit, a perfectly simple one—the radiograph has just caught a peristaltic wave, and if a later photograph had been taken the wave of contraction would have been seen to have moved nearer to the pylorus. My colleague Dr. Teall, in his radiographic examination of these cases, has repeatedly observed this sequence of events. I may also remark that peristalsis in pyloric stenosis is not limited to the contractile cylinder, but waves appear well up on the cardia; if it were not so, how otherwise would the appearance of obvious peristaltic waves commencing at the left subcostal margin and ending in the right flank be explained?

If this letter were not already far too long, I would like to have challenged the view that there is no fundamental distinction between pyloric stenosis and pyloric spasm. I cannot, however, finish without once more expressing my thanks to Dr. Cameron for his lectures and my high appreciation of them.—I am, etc.,

Birmingham, May 13th.

LEONARD G. PARSONS.

## SLOW AND IRREGULAR HEART.

SIR,—It may reassure sufferers from slow heart, arrhythmia, extra-systoles, and other cardiac irregularities to hear of my personal experience of these during a long life.

I had an irregular pulse from childhood, and first noticed it at the age of 10. My pulse has always been slow—50 to 60 during rest. At the age of 14 extra-systoles began, and these have gradually increased in frequency until, in latter years, they have often caused great annoyance. At 40 I began to be troubled with paroxysms of auricular fibrillation, usually lasting eight hours or more. After enduring this condition for twenty-eight years I discovered incidentally that calcium lactate in small doses (15 grains daily at bedtime) was a successful remedy. This has kept me free from paroxysms for three years, though it has little effect, if any, on the extra-systoles. I have led an active life in body and mind, avoiding athletics and other artificial exercise, which I have always found to be a painful substitute for work; and now at the age of 71 I am still active, and am usually taken to be ten years younger.

My father suffered in a similar way, but died from other causes in his 76th year. Three relatives were affected with what seems to have been the same trouble; they were treated with digitalis and strychnine, and died before reaching my age. Digitalis, strophanthus, and strychnine have increased my trouble when tried. I found the best palliative for paroxysms of auricular fibrillation to be a large dose of chloral and potassium bromide.

I shall be glad to answer privately any letter forwarded to me; but in these columns I prefer to take cover behind the pseudonym of—

May 17th.

ARRHYTHMIA.

## RELAPSE IN MEASLES.

SIR,—I was greatly interested in the letter on relapse in measles, by Sir J. W. Moore, in the *BRITISH MEDICAL JOURNAL* of May 16th (p. 946). I recently saw a case of this kind whilst acting as locum tenent in a general practice in Yorkshire.

A girl, 9 years of age, had an attack of measles which ran its usual course, the rash completely fading away, the temperature dropping to normal, and the other symptoms subsiding; I had told the parents that she might get up in two or three days. On the day she was to get up I was called to the house again, and found that the temperature had again risen, the symptoms were returning, and the rash was again making its appearance. The rash developed in the usual way, the other symptoms subsided, and the child made a rapid recovery.

The attacks seemed to be exactly similar, the only difference I noticed being the fact that during the second attack the spots were more profuse on the body and limbs, whereas during the first attack they predominated on the face. —I am, etc.,

Manchester, May 27th.

FRANK E. EDWARDS.

SIR,—Might there not be the same fundamental cause for relapse in measles as for relapse in vaccination? I vaccinated W. A. B. on April 17th, 1925, in four places on the arm, all of which reacted satisfactorily. After apparently complete recovery, recurrence of the pox occurred in one place on May 15th, a very rare event, as stated by the late Sir William Osler. The relapse in measles generally occurs about the end of the second week, and this case of relapse in vaccination occurred at a similar time, which is suggestive of a common underlying cause in the two conditions.—I am, etc.,

JOHN N. BEADLES, M.B., B.S. Lond.

London, S.W.16, May 16th.

## BACTERIAL VACCINES.

SIR,—I have now had the opportunity of consulting the two publications referred to by Professor Mackie in his letter (written on behalf of Dr. S. Davidson) which appeared in your issue of April 18th (p. 762).

As a result I have to confess that I by no means share

his view in the general interpretation of the very limited experiment referred to, which deals entirely with pneumococcus Type I. In the abstract of the earlier paper (*BRITISH MEDICAL JOURNAL*, December 27th, 1924, p. 1209) it is stated that of the animals prepared by various types of vaccine treatment those remaining in relatively good health showed the least resistance, and those with toxic symptoms were proved to have a serum of high protective immunity.

We are thus brought back in general terms to the conception which all novitiates in bacteriology were taught to imbibe some twenty-five years since, to the effect that active specific immunity was only to be acquired as the result of physical suffering.

Disregard is paid to modern conceptions—the outcome of extensive research—that physical suffering may be entirely eliminated in the process of active immunization either with bacterial substances or with their products, as with scarlet fever and diphtheria. Ramon, Glenny, and others have shown the great antigenic value of diphtheria toxin deliberately rendered inert according to animal tests for toxicity. In connexion with tetanus and the ordinary gas-gangrene-producing organisms there is the significant work of Glenny, Buxton, and others, who, in a recent publication, arrive at the terse conclusion, “Both specific toxin and toxoid are antigenic.”

Recent statistics show that in France—an important animal-industry country—from one-third to one-half of the total of veterinary practitioners are employing various forms of detoxicated vaccines in the treatment of bacterial infection, so that Ramon's work on anatoxins is having a wide repercussion.

Dr. Davidson's account of his experiments with the pneumococcus upon mice and rabbits displays certain technical errors.

1. The weights of the animals employed have been disregarded and the minimal lethal dose for mice of the broth culture employed is higher than that stated; far too few animals have been used for each test.

2. It is difficult to make comparison of the quantities of the several vaccines employed in the attempts at immunization, some of these vaccines being measured gravimetrically and others volumetrically, whilst the detoxicated vaccine is measured by the number of organisms.

3. With regard to the immunization of rabbits with the detoxicated vaccine it is stated that a total of 38,000 thousand millions was given intravenously to each animal, whilst those treated subcutaneously each received 88,000 thousand millions. (Sic.) Figures of such astronomical dimensions are somewhat beyond my comprehension, but a simple arithmetical calculation shows that if this statement be correct, each of these rabbits received a total of 770 c.c.m. intravenously—the last dose being 400 c.c.m.; also each rabbit treated subcutaneously received a total of 1,760 c.c.m.—the final dose in these cases being 1,000 c.c.m.! (Such heroic dosage seems to be rather within the limits of physical endurance of a horse of 17 hands.)

Table V (p. 77) epitomizes the results of the attempts to immunize six rabbits with the several vaccines, there being administered subsequently to each animal and also to one untreated control animal 1 c.c.m. of a broth culture of pneumococcus Type I. There are, in effect, seven different experiments with only one animal per experiment. Only two animals survived the test—namely, the rabbit previously prepared with a heat-killed broth culture and also the rabbit prepared with defatted vaccine. Yet the author formulates a “general conclusion,” and states:

“As judged by I. Production of antibodies, II. Protection to lethal doses of micro-organisms, detoxicated and defatted vaccines have no immunological value comparable to that of ordinary heat-killed vaccines.”

Such evidence as is adduced by the author is not only of the scantiest nature possible; it is incredible in material places and is opposed to the author's own finding.

I find that at the discussion which ensued subsequent to the reading of Dr. Davidson's paper, Professor Mackie makes the statement, “The results have been exceedingly decisive and do not admit of any serious criticism,” and I therefore feel impelled to submit this analysis.—I am, etc.,

Hendon, N.W.4, May 16th.

MYER COPLAND.

## CLEAN MILK.

SIR,—I notice that Dr. Chalmers Watson has been drawing attention to the fact that very few hospitals or local authorities go in for Grade A milk, and that none of the leading general hospitals or children's hospitals in Scotland have yet given this subject serious consideration.

The City of Leicester Isolation Hospital and Sanatorium have been using Grade A tuberculin-tested milk for all patients and resident staff since May, 1923, a period of two years. As we have 340 beds for patients, including infectious diseases and cases of tuberculosis (both pulmonary and non-pulmonary, adults and children in all stages), and a resident staff of 88, our average milk consumption is 50 gallons a day.

Our milk supply is tested both bacteriologically and qualitatively by us after delivery here, once a week in summer and twice a month in winter on an average, in order to ascertain if it is up to standard. We have been quite satisfied with the milk since we commenced taking it two years ago.—I am, etc.,

F. A. E. SILCOCK, M.B., D.P.H.,

Medical Superintendent, Leicester Isolation Hospital  
and Sanatorium.

May 18th.

SIR,—In a letter just received from Dr. McMichael, M.O.H. Paisley, I am informed that, following on a recent decision of the town council, only certified milk is now supplied to all the patients in the three municipal hospitals in Paisley—the Fever Hospital, the Tuberculosis Hospital, and the Maternity and Child Welfare Hospital. So far as I am aware, Paisley has therefore the distinction of taking the lead in establishing a much needed reform. Reference may also appropriately be made to the model dairy established by Sir R. Philip some years ago for the supply of clean milk to the Tuberculosis Hospital, as part of the general Edinburgh scheme for combating the disease, to the individual pioneer work (in Scotland) of Dr. Calder of Stow as a producer of certified milk on a commercial scale, and to the recent action of the county council of East Lothian in securing clean milk for its sanatorium.

For many years past a considerable amount of valuable work has been done on the subject of milk, notably at the National Institute for Research in Dairying, Reading, under the direction of Dr. Williams. This work, however, has largely remained outside the field of interest of the medical profession as a whole. It would appear that the time is now ripe for medical men to interest themselves in the question in a more intensive way than has so far prevailed. It is probably no exaggeration to say that, viewed from the necessary broad standpoint, there is no more pressing or vitally important question at the present time than the adequate provision throughout the country of a clean milk supply.—I am, etc.,

Edinburgh, May 17th.

CHALMERS WATSON, M.D.

## SEVERE DERMATITIS FOLLOWING ULTRA-VIOLET LIGHT.

SIR,—It would be useful if Drs. MacCormac and McCrea would state the type of lamp used in the case of severe dermatitis following ultra-violet light recorded by them in the JOURNAL of April 11th (p. 693), and would mention the voltage, the distance of the patient from the lamp, and whether it was possible for him to turn over in his sleep. I have seen several cases of severe dermatitis due to ultra-violet irradiation, but the lesion has always been limited to the part exposed. Moreover, none of these "bad sunburns," although often producing large blisters, have become septic. After blistering the serum exuded from the blister, which then collapsed, and the dead cuticle peeled off. A raw surface was left which quickly healed without pus formation. I have used the rays to treat ordinary heat burns, and these almost invariably healed much quicker than is usual with any other method of treatment.

I think that a patient exposed to any modern source of ultra-violet rays for seventy minutes would suffer from a severe dermatitis unless his skin had been well pigmented

by previous treatment. Undoubtedly all ultra-violet treatment should be supervised by a medical man.

As to the comparative merits of the carbon arc lamp and the newer sources of ultra-violet rays, it is too big a subject to touch on in this letter.—I am, etc.,

Smethwick, May 4th.

Clyde McKENZIE, M.B.

## X-RAY DIAGNOSIS.

SIR,—The above term is creeping into medical language, and since it is bound to convey a wrong impression its use is unfortunate. The function of the radiologist is to report findings, and the report is one piece of evidence in a case upon which the clinician pronounces final judgement. In a court of law the judge sums up on the evidence given. Certain evidence may stand out above all else in importance, and so it is with radiological evidence. It is often the most convincing of the observations made, but this does not justify the term "x-ray diagnosis." A radiologist, if he be wise, does not attempt to make a diagnosis. He may on occasion suggest a pathological condition consistent with the x-ray appearances.

The correct diagnosis of a case rests upon the history, symptoms, and signs, and the last word is more often given by the latter. One was taught as a student that the first of the senses to be made use of in approaching a case is that of sight. Our sense of sight is limited in a very definite degree to the surface, but it can be extended to observations below the surface by bringing to our aid light of a different wave-length—namely, x rays—and translating the effect by photographic and other means into pictures possible of comprehension by means of human vision. Surely, then, one has not properly exhausted the first step in an examination until radiological evidence has been taken.

It cannot be said that diagnosis is easy, or that correct diagnosis is as common as we should like. Yet correct diagnosis is the very first step towards correct treatment! It is astonishing, then, to hear clinicians attempting to belittle the value of radiological examination. Assistance in any form towards the end in view—namely, the correct interpretation of a case—ought to be welcomed. The practice of underestimating and mistrusting x-ray evidence, at one time so common, is not so now, yet it is too prevalent. The cause of this is no doubt largely due to the fact that the clinician has been let down on occasions by reports based on wrong deductions. One so commonly hears the remark made that radiograms are deceptive, whereas it is the interpretation that is at fault. So long as the profession imagines that an x-ray examination merely consists in taking a photograph, misinterpretation is bound to occur.—I am, etc.,

Hove, May 7th.

C. GUY WHORLOW.

## Obituary.

HOWARD H. TOOTH, C.B., C.M.G., M.D., F.R.C.P.,

Consulting Physician to St. Bartholomew's Hospital and the  
National Hospital for the Paralysed and Epileptic.

VERY many readers will have seen with deep regret the brief announcement in our last issue of the death of Dr. Howard Tooth, the distinguished neurological physician, which occurred on May 13th after a long illness.

Howard Henry Tooth was a son of the late Frederick Tooth of Hove, Sussex. He was born on April 22nd, 1856, and was educated at Rugby and St. John's College, Cambridge, where he took the B.A. degree in 1877 and the M.A. in 1881. From Cambridge he went to St. Bartholomew's Hospital, obtained the M.R.C.S. and L.R.C.P. diplomas in 1880, and the M.R.C.P. in 1881, and graduated M.B. in the following year. He proceeded M.D. in 1883, choosing as the subject of his thesis the peroneal type of muscular atrophy. He was elected F.R.C.P. in 1888, and again chose a neurological topic—secondary degeneration of the spinal cord—for his Goulstonian Lectures delivered before the College in 1889; they were published in successive issues of the BRITISH MEDICAL JOURNAL during April of that year. He was elected assistant physician to the

Metropolitan Hospital in 1881; to the Hospital for the Paralyzed and Epileptic, Queen Square, at the end of 1887; and to St. Bartholomew's Hospital in 1895. On retiring from the active staff of each institution he was elected consulting physician.

During the South African war Dr. Tooth served as physician to the Portland Hospital, and was created C.M.G. in 1901. Later, under Lord Haldane's scheme for the Territorial Force, he was given the command of the Medical Unit, Officers' Training Corps, University of London Contingent, and this experience led to his appointment during the early part of the great war as officer commanding the 1st London Territorial General Hospital, which was staffed by his colleagues of St. Bartholomew's. In 1916 he became consulting physician to the troops in Malta, with the temporary rank of colonel A.M.S., and during the last year of the war he was consultant to the British Forces in Italy. He was twice mentioned in dispatches, and was created C.B. in 1918. Like his friend and colleague Sir Archibald Garrod, he received from the University of Malta the honorary degree of M.D.

Dr. Tooth was for many years examiner in medicine to the Universities of Cambridge and Durham. He was censor of the Royal College of Physicians in 1913-14, and had held office as President of the Neurological Section and Vice-President of the Medical Section of the Royal Society of Medicine. His presidential address to the former section on the "Growth and survival period of intracranial tumours" was published in *Brain* in 1912, and in the following year he contributed a paper on the treatment of cerebral tumours to the International Medical Congress held in London.

Old St. Bartholomew's men in every part of the world, and students from other schools who knew him at Queen Square, have affectionate memories of Dr. Howard Tooth in the wards and out-patient rooms. His teaching was practical, and given usually in the form of a quiet talk between colleagues of equal standing. Handsome, courteous, and upright in bearing, with kindly smile and sympathetic voice, Dr. Tooth won the hearts of all about him.

Dr. Tooth was twice married. His first wife, a daughter of Edward Price, died in 1905; his second wife is a daughter of the Rev. C. S. Chilver. He leaves one son and two daughters.

We are indebted to Dr. H. MORLEY FLETCHER, senior physician to St. Bartholomew's Hospital, for the following tribute:

By the death of Howard Tooth his former colleagues have lost one who had a high place in their affection and esteem. He had to an unusual degree a bright and sunny temperament which endeared him to all, and this was combined with a most transparent honesty of character to which the faintest touch of chicanery was abhorrent. During the many years I had the privilege of knowing him I do not think I ever heard him make a disparaging remark about anyone.

As a neurologist his advice was sought for by his colleagues, and he would spare neither time nor trouble to help in a difficult case. His name is particularly associated with the peroneal type of muscular atrophy, but in more recent years—1912 and 1913—he did valuable work with regard to cerebral tumours.

He had many interests outside his profession: he was devoted to music, and during his residence in London played regularly in orchestra. He was a first-class musician, and many of his happiest hours were spent in his well equipped workshop. Later in life he became an ardent gardener, and up to his last illness work in his garden absorbed much of his leisure.

During the war he was one of the staff of No. 1 London General Hospital, and became the officer commanding until he was sent out as consulting physician to the forces at Malta. All who served under him at No. 1 Hospital can recall the pleasant way he had of dealing with the difficulties, both small and great, which are constantly liable to occur during war service, and how much we missed him when he was seconded for foreign service. His sunny presence will be missed by all who knew him. We offer our most sincere sympathy to his widow and children.

## Medico-Legal.

### LUNACY LAW AND ADMINISTRATION.

HARNETT v. BOND AND ADAM.

THE House of Lords, consisting of the Lord Chancellor and Lords Dunedin, Atkinson, Sumner, and Buckmaster, delivered judgement in the case Harnett v. Bond and Adam in the House of Lords on May 15th.

Previous proceedings have been reported in the *BRITISH MEDICAL JOURNAL*—in the King's Bench Division, March 8th, 1924, at pp. 449 et seq.; and in the Court of Appeal, April 12th, 1924, at pp. 692 et seq.

The plaintiff, Mr. William Smart Harnett, a farmer of Sittingbourne, Kent, having been detained as a lunatic at Malling Place, Kent, a home for the reception of lunatics of which Dr. Adam was the manager, under a reception order dated November 10th, 1912, made in accordance with Section 4 of the Lunacy Act, 1890, left the home on December 12th, 1912, on a leave of absence on trial order for twenty-eight days. This order, the form of which was settled by the Law Officers of the Crown, pursuant to Section 55 of the Lunacy Act, 1890, purported to empower the medical officer to take back the plaintiff at any time during the twenty-eight days if his mental condition required it. The plaintiff left the home with his brother, and on December 14th, 1912, he went alone to the offices of the Board of Control in Victoria Street, London, to ask if he could be put under the control of the police rather than his brother. Dr. Bond, a Commissioner in Lunacy, saw him, and, after referring to the file of the plaintiff's case, telephoned to Dr. Adam that the plaintiff was in an excited state and in his opinion unfit to be at large, and detained the plaintiff for three hours until the arrival of two attendants, who took the plaintiff back to Malling Place in a motor car. Upon arrival there Dr. Adam examined the plaintiff and detained him under the reception order. Thereafter, the plaintiff was detained in various mental homes until his escape on October 15th, 1921, when prominent alienists whom he consulted certified him sane. The plaintiff then brought an action against Dr. Bond and Dr. Adam, alleging conspiracy, assault, and false imprisonment, jointly and severally.

The case was tried before Mr. Justice Lush and a special jury, who found that the plaintiff was sane on December 14th, 1912; that Dr. Bond caused his detention at Victoria Street until the attendants arrived; that he did so for the purpose of his being detained at Malling Place; that Dr. Bond did not honestly believe that the plaintiff was of unsound mind, or was unfit to be at large, or was dangerous to himself or others, but that he did believe that the plaintiff had escaped from his brother's charge, and that was the reason he sent him back; that Dr. Adam honestly believed the plaintiff was of unsound mind and unfit to be at large on December 14th, but that he did not take reasonable care in taking the plaintiff back. Mr. Justice Lush directed the jury that in assessing damages they might take into consideration the whole period of the plaintiff's detention up to October 15th, 1921, if they thought it was the direct consequence of the acts of defendants on December 14th, 1912.

The jury awarded £20,000 damages against Dr. Bond and Dr. Adam jointly, and £5,000 against Dr. Bond for the detention at the offices for which he was alone responsible.

In the Court of Appeal (1924, 2 K.B. 517), Bankes, Warrington, and Scrutton, L.Js., held that this was a misdirection, for, even if the original detention was unlawful, it was not the direct cause of the plaintiff's subsequent detention, the act of retaking, his recertification on reception at Croydon Mental Hospital on February 25th, 1913, and other certificates of doctors and reports of visitors, each constituting a *novus actus interveniens* breaking the chain of causation. They held, further, that the form of the leave of absence order was warranted by Section 55, Subsection 3 (b) of the Lunacy Act, 1890, and that this order and the original reception order justified the manager in taking back the plaintiff and detaining him; also that the manager was protected by Section 330 of the Act of 1890, as he acted in good faith and there was no evidence upon which the jury could have arrived at their answer that he did not exercise reasonable care. A new trial was ordered against Dr. Bond for the detention at the offices, and judgement was entered for Dr. Adam.

This decision of the Court of Appeal was affirmed by the House of Lords, who further held that the manager was empowered by the leave of absence order to retake a patient on leave wherever he might be found; that the onus was on the plaintiff to prove that the manager had not used reasonable care in exercising this power; that if such power were exercised negligently then the remedy (if any) would be by an action for negligence and not by an action for false imprisonment.

#### The Lord Chancellor's Judgement.

The following is the text of the judgement delivered in the House of Lords, on May 15th, by the Lord Chancellor (Viscount Cave):

This is an appeal by the plaintiff in the action against orders of the Court of Appeal in England reversing a judgement of Mr. Justice Lush in his favour for £5,000 against the defendant Bond, and for £20,000 against the defendants Bond and Adam jointly, and ordering a new trial of the action as against the defendant

Bond and judgement to be entered in favour of the defendant Adam.

The appellant, Mr. William Smart Harnett, was, on November 10th, 1912, received by the defendant, Dr. George Henry Adam, as a private patient in a house licensed for the reception of lunatics and known as Malling Place, West Malling, in the county of Kent. The reception order was made on the petition of the appellant's brother, and it was not disputed on this appeal that at the date when the reception order was made the appellant was of unsound mind. After the reception of the appellant at Malling Place his mental health improved, and on December 12th, 1912, Dr. Adam thought it safe to permit him to be absent upon trial for a period under Section 55 (3) of the Lunacy Act, 1890. The consent required by the section was signed by two of the Visiting Justices for Kent, and was in the following form, which is said to have been approved by the Law Officers of the Crown:

"We, the undersigned, being two of the Visiting Justices of Private Asylums for Kent, hereby sanction leave of absence from Malling Place of William Smart Harnett on probation for the period of twenty-eight days, but this sanction is revocable by us at any time during that period; "Provided that the medical officer shall at any time before the expiration of the said period have power to take back the said patient into the licensed house, if his mental condition requires it."

The appellant accordingly left Malling Place on December 12th with his brother, who had been asked by Dr. Adam to take care of him, but shortly afterwards separated from his brother and went to his home at Sittingbourne. On December 13th he was seen by several persons, who formed varying opinions as to his sanity, and on that afternoon he went on to London and stayed at an hotel near Moorgate Street. On the morning of December 14th he called at the offices of the Commissioners in Lunacy in Victoria Street, taking with him £30 in a bag, and asked to see a Commissioner. The purpose of the appellant in making this call is not very clear; but it would appear from his evidence, and from a letter which he had written to the Commissioners on the preceding day, that he wished the Commissioners to hand him over to the care of the police, and took with him the £30 as payment or security for that purpose. The appellant had interviews with Mr. Dickinson, Secretary of the Board of Control, and with the respondent, Dr. Bond, who was the Commissioner in attendance at the offices on that day; and they both formed an unfavourable opinion as to his mental state, and, after consulting the file relating to his case, communicated with Dr. Adam on the telephone. Whether this telephone message was actually given by Dr. Bond or by Mr. Dickinson at his request, and what were the precise terms of the message, is left in some doubt; and this is by no means surprising, as the evidence relating to this conversation was given more than eleven years after it took place. But it appears clearly from the evidence given by Dr. Bond and Mr. Dickinson, as well as from that of Dr. Adam, that Dr. Adam was informed that the appellant was at the offices of the Commissioners, and was in a very excited state and unfit to be about by himself, and that Dr. Adam replied that he would send a car and two attendants for him. It was suggested on behalf of the appellant that the message was sent before Dr. Bond had personally interviewed the appellant, but I do not think that this was established; and in any case it is proved that Dr. Bond had a long conversation with the appellant before the car arrived and formed a clear opinion that he was unfit to be at large. Pending the arrival of the car, Dr. Bond caused the appellant to be detained (without the use of any violence) in a room at the offices; and on the arrival of the car the two attendants were taken to the room where the appellant was and took him back with them to Malling Place, where he arrived at about 5 o'clock in the afternoon. On the same evening, at about 7 o'clock, he was seen by Dr. Adam, who formed the opinion that he was much worse mentally than when he had been released on trial, and accordingly detained him under the reception order of November.

The appellant was confined at Malling Place until February 22nd, 1913, when he was removed to the Croydon Mental Hospital; and on February 25th, 1913, he was examined by the medical superintendent of that asylum and certified to be suffering from mania. Similar examinations and reports were made by the medical superintendent on March 25th, 1913, October 12th, 1913, and subsequent dates. On August 24th, 1917, the appellant was removed to the Holloway Sanatorium at Virginia Water, and he was again removed on April 30th, 1918, to St. Ann's, Canford Cliffs, and on April 29th, 1920, to Aylsham as a single patient, and at each of these places the reports and certificates required by statute for his continued detention were duly made and given. He was also, as the Act required, frequently seen by the Commissioners and the Visiting Justices, as well as by a Chancery Visitor; and to all these persons he appeared to be still of unsound mind and a proper person to be detained under care and treatment. On October 15th, 1921, the appellant escaped from the house at Aylsham; and, having remained at large for upwards of fourteen days, he could not be retaken under Section 85 of the Act, and remained at liberty. Shortly afterwards he was examined by two eminent medical practitioners having experience in mental cases, and they declared him to be of sound mind.

On May 31st, 1922, the appellant commenced these proceedings against Dr. Bond and Dr. Adam, and by his statement of claim charged them with conspiring together to cause him to be detained wards at Malling Place, and also with assault and false imprisonment, and claimed damages against both and each of them. No statement of claim, but Dr. Adam in his defence pleaded that he had acted in good faith and with reasonable care, and relied on Section 330 of the Lunacy Act.

The action was heard by Lush J. and a special jury; and after

a long hearing the learned judge summed up the case and put to the jury seventeen questions, which were answered as follows:

1. Did Dr. Bond cause the plaintiff to be detained at the office until the attendants came for him?—Yes.
2. Did he cause him to be sent back for the purpose only of his being examined by Dr. Adam, or for the purpose of his being detained at Malling Place?—Being detained at Malling Place.
3. Did Dr. Bond cause the plaintiff to be taken back?—Yes.
4. Was the plaintiff of unsound mind on December 14th, 1912?—No.
5. Was he fit to be at large?—Yes.
6. Was he dangerous to himself or others?—No.
7. Did Dr. Bond honestly believe that the plaintiff was of unsound mind?—No.
8. Or that he was not fit to be at large?—No.
9. Or that he was dangerous to himself or others?—No.
10. Did he believe that the plaintiff had escaped from his brother's charge? If so, was that his reason for having him sent back?—Yes.
11. Did he take reasonable care to ascertain the true facts?—No.
12. Did he honestly believe that Dr. Adam had retained a power of taking the plaintiff back during the twenty-eight days in the leave of absence order?—Yes.
13. Did Dr. Adam, when he received the telephone message and sent the car, honestly believe that the plaintiff on December 14th, was of unsound mind and unfit to be at large?—Yes.
14. That it was in his interest that he should be taken back to Malling Place?—Yes.
15. Did he take reasonable care in acting as he did?—No.
16. Did he make it known to the plaintiff that he was liable to be retaken if his mental condition required it?—No.
17. Was the detention of the plaintiff at the Commissioners' offices the act of Dr. Bond alone or was it really the act of both the defendants?—Dr. Bond.

It is common ground that the answer to question 10 was explanatory of the answers to questions 7, 8, and 9, the effect of the four answers being that Dr. Bond acted for the reason given in question 10 and not because of any belief, honest or otherwise, concerning the appellant's frame of mind. These answers having been given, the learned judge proceeded to address the jury upon the question of damages upon the footing that the confinement of the appellant during the whole period from his return to Malling Place until his escape from Aylsham was a direct consequence of the acts done by the defendants on December 14th, 1912; but being apparently uncertain on this point, and as to the joint liability of the defendants, he requested the jury to make alternative assessments in manner appearing in the following further questions and answers:

18. Damages against the defendants?—£25,000.
- (a) Apportion the sum of £25,000.—Bond £17,500; Adam £7,500.
- (b) Assess the damages on the footing that the defendants were only responsible for the detention up to February 22nd, 1913, and apportion it, the special damages being £82.—On this footing the total sum is £10,000; Bond £7,500; Adam £2,500.
- (c) Assess damages against Dr. Bond merely for detention at the offices, taking into consideration the whole purpose for which he was so detained.—£5,000.
- (d) Assess damages against Dr. Bond and Dr. Adam jointly on the footing that they knew the plaintiff would be deprived of the remainder of his twenty-eight days' liberty, and apportion that.—Total sum £9,800; Bond £7,400; Adam £2,400.

Upon these complicated findings, the learned judge was called upon to pronounce judgement, and, after hearing further arguments, he held that the chain of causation set up by the detention of the appellant at the Commissioners' offices on December 14th, 1912, was not broken, either when Dr. Adam, on examining the patient after his return to Malling Place, formed the opinion that he was then of unsound mind and detained him, or when the appellant was removed to Croydon in 1913, or in November, 1913, when there was a recertification, or at any subsequent removal or certification, and that it was quite open to the jury to treat the long detention as the direct consequence of the wrongful acts of the defendants, and on that footing he gave judgement against Dr. Bond for £5,000 and against both defendants for £20,000 with costs.

The defendants having applied to the Court of Appeal for a new trial, or judgement, that Court (consisting of Bankes, Warrington, and Scrutton, L.J.J.) unanimously set aside the judgement of Lush J., and ordered a new trial as against Dr. Bond and that judgement should be entered for Dr. Adam. As to Dr. Bond, the learned Lord Justices held that the chain of causation had been broken, not only when Dr. Adam decided to detain the appellant after his return to Malling Place, but at "innumerable points" after that date, and that it was plainly not permissible for the jury in assessing damages to treat the whole period of the appellant's captivity as directly caused by the events of December 14th, 1912. As to Dr. Adam, they held that under the terms of the leave of absence order he was entitled to retake the appellant at any time before the end of the twenty-eight days if, in his opinion, honestly formed, it became necessary to do so, and that there was no evidence upon which the jury could find want of reasonable care on his part. From this decision the plaintiff has appealed to this House.

As regards Dr. Bond, I feel no doubt whatever that the Court of Appeal was right in ordering a new trial. It is not disputed that, on the assumption that the findings of the jury as to the appellant's mental condition on December 14th, 1912, were correct, Dr. Bond had no right to cause the appellant to be detained at the offices pending the arrival of Dr. Adam's car, and is liable for damages for that illegal detention. But those damages must, in the authorities, be confined to such as were the direct consequences of the wrong committed, and to hold that the detention of the appellant at the offices for a few hours was the direct cause, not only of his being retaken and conveyed to Malling Place, but also of his being confined in that and other houses until October, 1921, appears to me to be impossible. Dr. Bond could not and did not direct and authorize Dr. Adam to retake the appellant or to confine him at Malling Place; the retaking and confinement were the in-

dependent acts of Dr. Adam, and each of them was a *nexus actus interveniens* sufficient to break the chain of causation. Further, the confinement of the appellant could not have continued during nine years without repeated examinations and recertifications by the proper authorities, and for the consequences of those events Dr. Bond cannot on any intelligible principle be held responsible. Whether the direct consequences of Dr. Bond's action in detaining the appellant at the offices ceased when the appellant was handed over to the two attendants and entered the car, or on his arrival at Malling Place, or later on his being examined by Dr. Adam, it is not now necessary to say. That may be a question to be determined at the new trial. But in any case it appears to me that those consequences cannot on any just view of the matter be deemed to have extended beyond 7 o'clock on the evening of December 14th, 1912. It was argued that even on this view of the matter the appellant was entitled to judgement against Dr. Bond for £5,000 as the damages assessed by the jury for detention at the offices, but this finding was obviously coloured by the directions given by the learned trial judge on the question of damages, and by the addition to the question of the words "taking into consideration the whole purpose for which he was so detained," and it appears to me that the whole matter ought to receive fresh consideration at the hands of a jury.

With regard to Dr. Adam, it is remarkable that, whereas he was charged in the pleadings with conspiracy and false imprisonment, no direct question was put to the jury as to either of these charges. The charge of conspiracy was apparently abandoned during the trial, and in any case it was plainly negatived by the findings of the jury in answer to the 13th and 14th questions. The charge of complicity in the false imprisonment at the Commissioners' offices was negatived by the answer to the 17th question, and there was no finding of false imprisonment by Dr. Adam at Malling Place. Why, then, was Dr. Adam held liable in damages at all? It must have been on the ground of the answer of the jury to the 15th question—namely, that Dr. Adam, in acting as he did (that is to say, in sending a car and taking the appellant back to Malling Place), did not act with reasonable care; and yet want of reasonable care was not charged against Dr. Adam in the pleadings, and the issue only arose on his defensive plea, founded on Section 330 of the Act. It appears to me that on this ground alone—namely, the total failure of the plaintiff to establish either of the charges made by him against Dr. Adam—the latter would be entitled to judgement. But in a case of this kind it is undesirable to base a decision on any narrow ground; and I propose to consider shortly whether either on the findings of the jury, or on the evidence, there is any ground for the judgement entered against Dr. Adam.

First, then, was there any ground for charging Dr. Adam with conspiring with Dr. Bond to cause the plaintiff to be detained and removed to Malling Place? Plainly not. There was no evidence to support such a charge, and it is negatived by the findings of the jury. I therefore dismiss this charge as wholly untenable.

Secondly, was there ground for charging Dr. Adam with false imprisonment—that is to say, with retaking or detaining the plaintiff without lawful authority? As to this, it was argued that under the terms of the leave of absence order set out above, Dr. Adam could only take back the appellant if the mental condition of the latter required it, and that, as the jury have found the appellant to have been sane on December 14th, 1912, this condition was not fulfilled. In my opinion there is no foundation for this argument. The provision in the leave of absence order empowering the medical officer to take back the patient "if his mental condition requires it" cannot mean that the medical officer is to take back the patient (if at all) at the risk of having it found by a jury many years afterwards that the patient's mental condition was consistent with his remaining at large. Some person must be the judge of the patient's mental condition at the time when the question arises, and this person can only be the medical officer in whom the power to retake him is vested. Nor is there any substance in the suggestion made by counsel for the appellant that the power to retake the patient reserved by the order could not be exercised by retaking him outside the licensed house. I think it clear that it was capable of being exercised wherever the patient might be found. When once the patient is retaken, the leave of absence order comes to an end, and he can be detained under the existing reception order.

But, thirdly, stress was laid on the finding of the jury as to want of reasonable care, and it was said that a medical officer could not retake a patient out on trial unless he acted with reasonable care in so doing, and that the onus was on him to prove reasonable care, and that if he failed to do so the retaking was void. This argument appears to me to be fallacious. The leave of absence order authorizes the medical officer to retake the patient if the patient's mental condition requires it. If this power is exercised negligently it may be that there is a remedy; but negligence does not make the retaking unlawful, and the remedy (if any) is by action for negligence and not by action for false imprisonment. But apart from this observation, I agree with the Court of Appeal in holding that in the present case there was no evidence on which the jury could properly find Dr. Adam to have failed to exercise reasonable care. It is suggested that he should have gone up to London himself or should have sent his assistant. But it was proved that the assistant was entitled to be absent from Malling Place on that afternoon, and that Dr. Adam could not leave the house without a medical officer; and in those circumstances he was entitled to rely on the information given him by Dr. Bond on the telephone, coupled with his own previous knowledge of the case, as sufficient ground for bringing the patient back, subject, of course, to the duty (which he performed) of personally examining him on his return. I agree that there was no evidence of negligence, and that Dr. Adam is entitled to judgement.

I desire to make one further observation. The fact that the appellant, whom the jury found to be sane in December, 1912, and whom they doubtless considered to be quite sane at the time when the action was heard, had been confined as a lunatic during the greater part of the interval between those dates has naturally given rise to anxiety. It was not proved at the trial or found by the jury that during that interval the appellant was of sound mind; but it is not impossible that the jury took that view and desired to compensate the appellant for his long detention by giving a verdict for heavy damages against the two defendants. If the defendants had been really responsible for an unjustifiable detention of the appellant during all those years the sum awarded might not have been excessive; but the full investigation of the case, both by the Court of Appeal and by this House, has led to the conclusion that no such responsibility can be justly laid on Dr. Bond or on Dr. Adam. The Lunacy Acts provide for the protection of the public against the risk of unjustified detention by forbidding the detention of any person as insane except on a proper certificate and in a place duly certified for that purpose, and by requiring that every patient so confined shall be personally seen and examined at regular intervals, both by the Commissioners in Lunacy and by the Visiting Justices, and shall be free to make complaint (in letters which must be forwarded unopened) to the Lord Chancellor or the Judge in Lunacy, to the Secretary of State, or to the Commissioners, or to the persons (generally his relations) on whose petition he has been confined. It may be—I do not say that it is—the fact that all these precautions are insufficient and that the Lunacy laws require to be further strengthened in the interests of the persons whom they may affect. But even if that be so, that is no reason for visiting with vindictive penalties persons who have acted in good faith, and who are not responsible for any defect in the law.

In my opinion (the Lord Chancellor concluded) the Court of Appeal came to the right decision, and I move your lordships that this appeal be dismissed with costs.

#### Lord Dundedin's Judgement.

The following is the text of the judgement delivered by Lord DUNDÉDIN:

I have never had a shadow of hesitation in thinking that the judgement of the Court of Appeal was right. Mr. Harnett was detained in a private asylum under a reception order against which nothing has been said. He was then liberated for a period of twenty-eight days on trial under a leave of absence order signed by two Visiting Justices, but with a proviso authorizing the medical officer at any time during the twenty-eight days to take back the patient if his mental condition required it. Being out of the asylum in virtue of the leave of absence order, he, of his own accord, presented himself at the office of Dr. Bond. He saw Dr. Bond, who, having identified his case on the file, knew that he had come from Malling Place. He considered him to be in a very excited state, and thought it would be well that Dr. Adam should see him. He telephoned to that effect and a motor car with two attendants was sent to take him to Malling Place. Pending the arrival of the car Harnett was forcibly detained. For that detention it is admitted Bond had no legal justification. But what was the direct result of it? Only that Harnett was examined by Adam. It is true that a question was put to the jury: Did Dr. Bond cause Harnett to be sent back for the purpose only of his being examined by Dr. Adam or for the purpose of his being detained at Malling Place? To which they answered: Being detained at Malling Place. But the question, in my opinion, was illegitimate and misleading. Bond had no power to say that Harnett should be detained at Malling Place, and nothing that Bond thought or intended could make any difference as to Dr. Adam's power to put an end to his liberty on probation or his responsibility for taking that step. To ask the jury whether Bond's purpose in sending him back to Adam was that he should be detained at Malling Place was, if they were to answer as they did, simply to ask them to affirm a *non sequitur*. Conceivably, though I doubt it, such a question might have been founded on averments as to a malicious motive on Bond's part with an intent to injure, but there was nothing of that in the case. Following on their answer to this question, the jury were instructed that they could give damages for the whole period of Harnett's detention, though that detention began, as already stated, by Adam's determination to end the period of probation, and was continued through all the years Harnett was in different places of confinement under renewed orders of different medical men. Such a suggestion has only, in my judgement, to be stated to be rejected. I look on it as preposterous.

As to Dr. Adam, I think he is clearly, in the circumstances, protected by Section 330 of the Lunacy Act.

I feel bound to add that the question of whether a person so admitted can under existing safeguards be kept for an unduly long period in a lunatic asylum is not the question in this case. Indeed, the learned judge expressly told the jury they would not be called on to say what was the plaintiff's mental condition during the nine years of detention. The course of inquiry permitted in the case eluded strongly, in my judgement, with that pronouncement.

Lord ATKINSON: I concur.

Lord SUMNER: I concur.

#### Lord Buckmaster's Judgement.

The following judgement was delivered by Lord BUCKMASTER: According to the verdict of the jury in this case, the plaintiff while a sane man has been imprisoned in a private lunatic asylum, and it follows that he has suffered a grievous wrong, for which no money payment can provide an adequate compensation. The jury have obviously been impressed with the gravity of the position, and have given a verdict in favour of the plaintiff, which has resulted in a judgement for £5,000 as damages against Dr. Bond

and £20,000 against Dr. Adam and Dr. Bond jointly, who, they say, were in their several degrees held responsible for the injuries that he sustained. The only question is whether Dr. Bond and Dr. Adam, together or separately, are legally liable for these sums. Dr. Bond is one of the Commissioners in Lunacy, whose offices are in 66, Victoria Street. Dr. Adam is the licensed proprietor of a home for the reception of persons of unsound mind at West Malling, in the county of Kent. On November 10th, 1912, Dr. Adam received the plaintiff in this establishment under a reception order which has not been challenged in these proceedings. On December 12th, thinking the plaintiff sufficiently restored to justify his release upon a probation order, the plaintiff was permitted to leave the establishment in company with his brother. The brother, however, was not responsible for his safe keeping, nor was the plaintiff placed under his control. On the morning of December 14th, at about 10.15, the plaintiff appeared at the offices of the Commissioners in Lunacy with £30 in a handbag, and asked to see a Commissioner. He said that he desired that the money should be deposited with the Commissioners to pay for a man to be sent to his house to prevent his being returned to the asylum. The statement as to what actually occurred and the true sequence of events is far from plain. The plaintiff's own account is not consistent, nor does Dr. Bond's memory agree exactly with the memorandum taken at the time. Dr. Bond appears to have thought that the plaintiff had eluded his brother's custody, and this may be explained by one of the plaintiff's statements in evidence when he said he told Dr. Bond, "I am to be under my brother for twenty-eight days." Influenced, it may be, by this, Dr. Bond communicated with Dr. Adam on the telephone, informing him that the plaintiff was there, and stating that he did not think he ought to be at large. The plaintiff stayed at the offices from 10.15 to 1.30; at 1.30, when he proposed to go for lunch, he was informed that he was not at liberty to go, and two efforts that he made to leave were prevented, but it is not suggested that any actual force or violence was exercised. He was, however, detained until about 2.30, when two attendants, sent by Dr. Adam from West Malling, arrived in a motor car, when he was given into their custody and by them taken back to Dr. Adam, and he remained under restraint at one institution or another from that time until his escape in 1923. The detention by Dr. Bond was an unlawful act for which he is responsible in damages. And it was decided by the learned judge that the measure of these damages might be taken in terms of the whole period of the plaintiff's confinement. I am unable to see how this can be supported. Dr. Bond had no power and no authority over Dr. Adam, and when once the plaintiff was returned to West Malling the duties with regard to his custody devolved upon and were discharged by Dr. Adam alone. If Dr. Adam had thought that, whatever appearance the plaintiff had presented at Victoria Street, he was none the less fit to be at liberty, it was his plain duty to have acted accordingly, nor can I think that any statement made by Dr. Bond upon the telephone as to what he thought can have caused Dr. Bond to share in or be party to the judgement that Dr. Adam formed. From the time when Dr. Adam reassumed control Dr. Bond's responsibility ceased. The Court of Appeal had held that this was the time when the plaintiff actually returned to West Malling; there has been no appeal from this judgement, and it is, therefore, unnecessary to consider whether it did not cease at the earlier moment, when the plaintiff was placed in the charge of Dr. Adam's assistants at Victoria Street. The jury have, however, found that Dr. Bond did not honestly believe that the plaintiff was of unsound mind, and an attempt is made to explain this verdict by saying Dr. Bond acted on the belief that the plaintiff had escaped from his brother's custody. The explanation appears to me inadequate; whatever mistake Dr. Bond may have made, I can find nothing whatever in the evidence that on any interpretation of the word can cast the least question on his honesty, and I think it is to be regretted that a question should have been left to the jury in such a form that the verdict taken upon it must, in the plain meaning of the words, cast a reflection upon Dr. Bond's character which no sophistry can explain away. One injustice cannot be remedied in committing another.

Returning now to the case against Dr. Adam, the first thing to decide is what were his powers after the plaintiff had been liberated under the probation order. I have no desire to repeat what has already been said upon this point; when once it be accepted that such an order is in the nature of an experiment to try whether a man is fit to be restored to complete liberty, it appears to me to follow that the powers conferred by the reception order, including complete control of the person named in the order, are merely in abeyance, and at any time if the custodian honestly thinks it is in the interest of the patient the control can be resumed and the patient taken back. Any other contention would result in this: that if the patient completely broke down during the period of probation, it would require a new reception order before he could be taken back, and of this I can find no trace in the provisions of the statute. Dr. Adam was, therefore, at liberty to retake the plaintiff, and however deplorable may have been the mistakes which the verdict of the jury has decided were made, they have completely acquitted Dr. Adam in taking him back of doing any act except in what he honestly believed to be the interests of the plaintiff.

I am not impressed with the criticism about the entry in Dr. Adam's book as to the plaintiff's delusion with regard to drugs. It has never been suggested that the book was fabricated, nor is it entertained after the apprehension which the plaintiff admits he might have been both felt and expressed at an earlier date. However this may be, I can find no evidence that Dr. Adam so failed in the discharge of his duties as to render him liable in damages, and I agree with the judgement of the Court of Appeal that as against him the proceedings fail.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

THE Vice-Chancellor announces that applications for the E. G. Fearnside scholarship for clinical research into organic disease of the nervous system must be sent to the Registry of the University before June 20th. The scholarship is open to graduates in Medicine or to graduates in Arts who have passed Part II of the Natural Sciences Tripos.

At a congregation held on May 15th the following medical degrees were conferred:

M.D.—H. J. Paterson, G. A. Harrison, T. L. Hardy.  
M.B.—E. G. Holmes.  
B.Chem.—W. Brockbank.

### UNIVERSITY OF LONDON.

#### Senatorial Election.

THE result of the election for a representative of medical graduates on the Senate was the re-election of Dr. E. Graham Little, M.P. for the University; he received 827 votes, against 231 for the other candidate, Mr. T. B. Layton, D.S.O., M.S.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary comitia of the Royal College of Physicians was held on May 14th, when the President, Sir Humphry Rolleston, was in the chair.

The minutes of the Censors' Board were read.

#### Lectureships.

The following appointments were made to lectureships: Dr. Bernard Hart to deliver the Goulstonian lectures, Dr. A. Shadwell the FitzPatrick lectures, and Sir Thomas Horder the Lushington lectures in 1926.

#### Fellowship.

The twelve Members elected to be Fellows, at the comitia on April 30th (BRITISH MEDICAL JOURNAL, May 9th, p. 935), were admitted.

#### Licence.

The following supplementary list of 96 candidates to whom licences had been granted was submitted:

\*Agnes L. Adam, D. Aernman, E. L. Anguste, C. W. Bamford, P. S. Bell, R. H. Bestawros, A. T. Bettinson, Margaret Bowstead, P. D. Braddo, \*Gwendolyn J. Brooke, \*Stella M. Brown, \*Dora M. Cadman, \*Mary E. Campbell, W. L. Chiesman, \*Lilceia M. Clarke, \*Glady's M. Clarke, \*Walfred M. Clement, D. R. T. Clendon, J. Cohen, R. W. Cunningham, S. H. Daniel, Gwynon Davies, H. J. Davies, D. S. Dixon, J. V. Dockray, D. C. Drake, W. Egan, V. H. Ellis, A. J. K. Fiach, \*Barbara Fiach, \*Walfred M. Fish, V. L. Fisher, M. Footerman, G. V. Gollerkeri, A. S. Gough, R. Green, C. J. Groseli, R. F. Guymer, L. B. Haye, J. B. Hayes, \*Barbara J. Hick, \*Nancy M. Hill, A. B. Hill, A. T. Howell, J. U. Humm, \*Dorothea A. C. Hunt, J. N. Jacobson, H. Kessel, A. M. Lazarus, S. Lerner, S. Levi, C. J. Lovering, D. A. Lubbock, J. W. McGuire, A. C. MacLeod, D. H. MacLeod, D. R. Martin, A. Mead, G. C. Michael, \*Ruth L. Milne, E. F. Molony, J. P. Monkhouse, H. Moore, A. H. Morley, V. M. Morris, I. S. Moscow, G. W. Murray, G. H. Pringle, P. E. Pryor, \*F. Morris, I. S. Moscow, G. W. Murray, G. H. Pringle, P. E. Pryor, A. T. Rees, \*Nellie H. Reynolds, Ross, \*Edith M. Ross-Johnson, \*Ell. H. E. Schulz, H. J. Selby, \*Ethel, K. A. Soutar, J. MacN. ora, J. D. Swyer, K. H. Tan, A. A. van Bauren, T. E. Walsh, H. G. Wimbush.

\* Under the Medical Act, 1875.

#### Membership.

Dr. Hugh Roger Smith, who relinquished his membership in 1919, was granted permission to resume it.

#### Appointments.

Dr. Raymond Crawford was appointed a member of the Committee of Management, to fill the vacancy caused by the death of Dr. Ormerod.

The President announced the appointment of Sir Percival Horton-Smith Hartley as representative of the College at the Conference of the National Association for the Prevention of Tuberculosis.

#### By-laws.

It was decided to appoint a small subcommittee to codify the by-laws, in view of recent alterations in them.

The President then dissolved the comitia.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on May 14th, when the President, Sir John Bland-Sutton, was in the chair.

#### The late Sir Rickman Godlee.

The death of Sir Rickman John Godlee, Bt., K.C.V.O., F.R.C.S., past president and past member of the Council and of the Court of Examiners, was reported, and the following vote of condolence was passed:

That the Council hereby express their regret at the death of Sir Rickman Godlee and their very sincere sympathy with Lady Godlee in the great loss which she has sustained. The Council also express their grateful sense of the many services to the College by Sir Rickman Godlee, and especially his long and able service as President, and his many achievements which will cause his name always to be held in honoured remembrance.

*Diplomas.*

Diplomas of Membership were granted to 234 candidates. Jointly with the Royal College of Physicians, diplomas in public health were granted to 15 candidates and in tropical hygiene and medicine to 22 candidates. (The list of names appeared in part in the report of the meeting of the Royal College of Physicians published in our issue of May 9th, p. 905; the remainder are printed in the present issue.)

*Court of Examiners.*

The vacancy on the Court of Examiners caused by the resignation of Mr. G. Percy Dodds-Parker will be filled at the ordinary Council in June.

*Honorary Fellowship.*

Professor Antonin Gosset of Paris, who was elected an Honorary Fellow of the College on June 12th, 1919, was introduced and signed the Roll of Honorary Fellows and was presented with the Diploma of Honorary Fellowship.

## Medical News.

THE next session of the General Medical Council will begin on Tuesday, May 26th, when the President, Sir Donald MacAllister, Bt., K.C.B., M.D., will take the chair at 2 p.m. and give an address. The Council will continue to sit from day to day until the business is finished.

THE KING has approved the reappointment of Sir David J. Galloway, M.D., as an unofficial member of the Executive Council of the Straits Settlements.

A COURSE of four lectures on physics will be delivered by Sir Robert Armstrong-Jones, M.D., at Gresham College, on Tuesday, May 26th, and three following days, at 6 p.m. on each day. Admission is free. The subject is the history of medicine from the earliest times to the mediæval period (about A.D. 1400).

THE annual dinner of the West London Medico-Chirurgical Society will be held at the Trocadero Restaurant, Piccadilly, to-day (Friday, May 22nd), at 7.30 for 8 p.m.

THE annual meeting of the supporters of the Lebanon Hospital for Mental Diseases, Asfuriyeh, near Beyrout, Syria, will be held in the rooms of the Medical Society of London, 11, Chandos Street, W., on Wednesday, May 27th, at 3.30 p.m. The chair will be taken by Dr. E. W. G. Masterman, who has recently visited the hospital, and the speakers will include Sir Wyndham Deedes and Pastor Hoffmann de Visme. Tea will be served at 4.30.

THE Fellowship of Medicine announces a lecture by Mr. G. Gordon-Taylor on May 25th on the prevention and treatment of shock in the surgery of the abdomen. The following courses have been arranged: A course in venereal disease, at the London Lock Hospital, Dean Street, and in dermatology, at St. John's Hospital, each beginning on June 2nd and lasting four weeks; clinical demonstrations at the London School of Hygiene and Tropical Medicine, from June 3rd to 25th; a course in gynaecology at the Chelsea Hospital for Women, June 8th to 27th; lectures and demonstrations on sunlight treatment, artificial pneumothorax, the electrocardiograph, etc., at the Victoria Park Hospital, from June 8th to 20th; a course in urology at St. Peter's Hospital, from June 15th to July 11th; an intensive course in medicine, surgery, and the specialties, at the London Temperance Hospital, from June 22nd to July 4th. The syllabus of each of these courses, and the programme of the Fellowship of Medicine, may be obtained from the Secretary at 1, Wimpole Street, W.1.

THE International Conference for the Use of Esperanto in Pure and Applied Science, which was held in Paris from May 14th to 16th, was attended by delegates of 112 societies, the representative of the British Medical Association being Dr. A. A. Martin of Eastbourne. M. Agourtine of Paris reported on the progress made since the first meeting of Esperanto doctors held in Cambridge, and the formation of a medical association (known as "Teka") in 1908. The activity of this association, suspended during the war, was revived in 1922, and considerable interest had been shown by many medical practitioners, especially in Japan. Another report on Esperanto and pharmacy related the progress of the International Pharmacopœia proposed in 1910, the associated federation being established in 1912. It was reported that the difficulties in establishing an international nomenclature were being gradually overcome.

DR. OSCAR M. HOLDEN, on relinquishing the medical officership of health for Dowsbury to take up a similar post in Blackburn, has been presented by the staffs of the public and school medical departments of the Dowsbury Corporation with a silver flower vase.

THE house and library of the Royal Society of Medicine will be closed on Whit-Monday, June 1st.

A FESTIVAL dinner in aid of King's College Hospital was held at the Savoy Hotel on Wednesday, May 20th, with H.R.H. the Duke of Connaught in the chair.

THE British Social Hygiene Council is the name by which the National Council for Combating Venereal Diseases will be known in future. This change, we are informed, does not mean that any less attention will be given to direct propaganda and public enlightenment on the medical aspects of venereal disease, but that it is recognized that the medical field is not the only one in which efforts can be made towards building up conditions calculated to lead to a permanent diminution of disease.

THE annual report for 1924 of the Society for Relief of Widows and Orphans of Medical Men shows that the invested income has increased by £1,000, and now amounts to £148,650. By the by-laws only the income of this investment may be used for the payment of grants and expenses. The total income during the year was increased slightly, reaching the figure of £5,136 0s. 10d., the working expenses being £359 19s. 1d. Of this income, £349 15s. was received from subscriptions and donations, £68 5s. from life subscriptions, and £600 from legacies. The sum of £4,961 18s. was distributed in grants of different kinds, and on December 31st there were fifty-one widows and seven orphans in receipt of them. During the year five widows had died, including one who had been in receipt of assistance since 1847; her late husband paid in subscriptions £37 16s., and she received £3,250 in grants. Another widow, whose husband had paid £12 12s., received in grants £1,885. Such examples illustrate the great advantages gained by medical men becoming members of the society, which was founded in 1788. Membership is open to any registered medical practitioner who at the time of his election resides within twenty miles of Charing Cross. Should a member remove outside this radius, even beyond the British Isles, he nevertheless remains a member of this society if he conforms to the by-laws. Relief is granted to the necessitous widows and orphans of deceased members of three years' standing and to life members. Further information may be obtained from the secretary of the society, 11, Chandos Street, Cavendish Square, W.1.

THE third congress of the Italian Association of Hygiene will be held at Cagliari and Sassari in Sardinia from June 5th to 14th under the presidency of Professor Achille Sclavo. Further information can be obtained from the general secretary, Dr. Giovanni Palomba, via Vittorio Veneto 96, Rome.

THE seventeenth Russian Congress of Surgery will be held at Leningrad from May 26th to 31st, at the same time as the Congress of Therapeutics. The principal subject for discussion is the treatment of acute infective osteomyelitis and its sequelae, which will be introduced by Dr. F. N. Krasnobayev. The clinical aspects and surgery of the vegetative nervous system will be discussed at a conjoint meeting of the two congresses by Drs. S. D. Pietuev, S. P. Fedorov, and E. R. Hessé. The subject of transplantation of endocrine glands will be opened by Professor V. A. Oppel.

THE fifth International Congress for the Protection of Childhood, which was to have been held in Madrid from April 12th to 19th, was postponed. Further information can be obtained from Dr. A. Bandelae de Pariente, 10, Square Monecy, Paris.

THE German Society for Combating Venereal Disease has arranged for the production of Briex's play *Les Avariés* in several Berlin theatres.

THE medical faculty of Montpellier has celebrated the fourteenth anniversary of the nomination of Professor Forgeat to the chair of clinical surgery by presenting him with a volume containing sixty papers by his students and friends.

THE monthly magazine, *The Temps*, which was originally the publication of the patients and ex-patients of Wooley Sanatorium, near Hexham, has now been extended to include propaganda and the general health activities of Northumberland. All profits from its sale are devoted to the Wooley Settlement Scheme, whereby employment under ideal hygienic conditions is provided for the patients at the sanatorium. The April number contains a summary of the health services of the county of Northumberland, articles on general health topics, tuberculosis, and the Wooley Sanatorium and Settlement.

THE value of the Zambaco prize awarded by the Société Française de Dermatologie et de Syphiligraphie has been raised from 800 to 1,500 francs. Candidates should send in their essays to the General Secretary, Hôpital St-Louis, Paris, not later than November 30th.

A RUSSIAN Society of Endocrinology has been founded at Moscow. It is proposed to start a journal and a library. Medical men and biologists are invited to send copies of their publications of the last ten years to the secretary, Dr. N. A. Schereschewsky, Arbat 26, Moscow.

## Letters, Notes, and Answers.

Up to and including Thursday, May 28th, all communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, 429, Strand, W.C.2.** After May 28th the postal address of the Editorial Department will be "British Medical Journal, British Medical Association House, Tavistock Square, W.C.1" (see p. 979).

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2.

The TELEPHONE NUMBER of the **BRITISH MEDICAL ASSOCIATION** and **BRITISH MEDICAL JOURNAL** is **GERRARD 2630** (Internal Exchange).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westrand, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London.*

MEDICAL SECRETARY, *Mediscera Westrand, London.*

The address of the Irish Office of the **British Medical Association** is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

### QUERIES AND ANSWERS.

#### TREATMENT OF ONYCHIA.

DR. J. FRASER MACKIE (Halkirk, Caithness) asks for suggestions for the treatment of a case of very chronic onychia. The patient finds it impossible to get a situation owing to the unsightly condition of her hands.

#### INFANT THERAPEUTICS.

"AN ELDERLY PRACTITIONER" writes from Australia: (1) Under what conditions is tea used in infantile therapeutics? Still mentions it incidentally in his book without giving particulars. (2) What is the objection to giving fruit juice, such as orange juice, before the age of 3 months?

\* \* \* We are indebted to Dr. Eric Fritchard for the following replies to these questions:

(1) Tea, in the form of a weak infusion, can be usefully employed in the treatment of febrile conditions in infancy, when the temporary suspension of food is indicated. It is specially useful in influenza with looseness of the bowels, also in the troubles connected with dentition. It has a soothing influence on the nervous system, and often induces sleep. The alkaloid caffeine, to which the therapeutic effect of tea is doubtless due, may be substituted for the infusion if accurate dosage is required: 1 grain of caffeine citrate may safely be given a baby 3 months of age.

(2) There is no objection to the giving of fruit juice to young babies. It has become a habit or tradition to delay its administration until they are about 3 months of age. Reliance is placed on the fact that infants are usually born with some reserve of the antiscorbutic vitamin, but it is not safe to trust to this supposition; the infant has the same need for this vitamin at 1 month as it has at 6 months, and some paediatricians order grape juice or orange juice from the 2nd week of life onwards without intermission, not only in cases of artificial feeding, but in breast-feeding also.

### LETTERS, NOTES, ETC.

#### "CENTRAL FIXATION."

AN assistant medical officer of health has sent us a cutting from a local newspaper containing a report of some remarks made by a town councillor on the annual report of the school medical officer. The councillor commented on the number of children fitted with spectacles, which, he said, would be a handicap to them later on when situations were sought. "As the Education Committee myopia, etc., now to the fore, called 'central fixation,' and it had done excellent work, not only here, but very widely in America. Not only were the young treated successfully, but old people than adding it meant six months' rest for a child, it was better proved that spectacles were not by any means always needed."

Our correspondent is confused by this statement and asks for an explanation.

We have referred the matter to Mr. Bishop Harman, who has been good enough to send the following instructive reply:

"Central fixation" is a perfectly well known and established term in ophthalmic work. It denotes the power of the normal eye to look directly and fixedly at a given object—that is, to bring the macula into line with the object to be viewed. Unless this be done there is no clear vision, for detailed vision is only obtained at the restricted area, or rather point, of the macula. Every normal eye has central fixation, whatever the error of refraction may be. The myope fixes centrally, so does the hypermetrope, but by reason of the error of focus images are not seen distinctly, even though there is central fixation. With proper correcting lenses the badly focused eyes obtain with central fixation clear and defined vision. An eye which has become amblyopic from disuse, as in children with squint, loses central fixation; when the good eye is covered the squinting eye is unable to fix a given object, for the macula has lost its sensitiveness. Many conditions of defect of the eye from congenital and infantile disease are associated with loss or absence in whole or part of central fixation—for example, the infant who has suffered from ophthalmia neonatorum, even though it has escaped obvious damage to the tissues of the eye, may be found a year or so afterwards to have nystagmus. The closure of the eyes by disease during the first three weeks of life prevented the appropriate stimuli reaching the maculae, so that there is poor development and central fixation is imperfect; the nystagmus is due to this. So also with miner's nystagmus: there is a diminution of good central fixation. A whole host of cases with congenital nystagmus show the same poor central fixation. Failure of central fixation can scarcely be remedied. The suggestion that "central fixation" is a substitute for glasses has no meaning. I do not know whether some quack has attempted to pervert the term for ulterior purposes, as have the osteopaths and such other brigands of other medical terms. Anything is possible in these days. But on the face of it the statement in this cutting would not appear to imply this. It seems that the worthy councillor has become entangled in the statements which he has had from a young doctor. The need for spectacles for the correction of considerable errors of refraction in school children is not a matter for debate. The facts have been established for many years. Numberless school medical officers have published carefully documented records of the examination of large blocks of children, showing the refraction of the eyes and the vision obtained. These have been collected on more than one occasion and included in the annual report of the Medical Officer of the Board of Education. The children are born with these defects. Proof of that may be found in a paper I read at the Ophthalmological Society in 1919 (*Transactions*, p. 79). That paper gave a full record of the examination of the refraction of the eyes of all the infants in a good class London school; the examinations were made under mydriasis; 358 infants were examined. Taking all those who had less than 2D. of hypermetropia and 0.5D. of hypermetropic astigmatism as fair average eyes which need no assistance, it was found that 65.1 per cent. had average eyes and 34.9 per cent. had eyes with such errors of refraction as would or were likely to need the help of glasses. For at least 10 per cent. glasses would be imperative if any school work needing serious study were to be undertaken; otherwise, the child would be put to injurious strain, or the educational provision would be wasted on the child.

#### BUYING A CAR.

The *Autocar* of May 15th is issued as a special number devoted mainly to the interests of new motorists. It contains advice on selecting a car; a reference table, which gives a summary of the horse-power, tax, weight, price, and other details of each car; and an article in which the mechanism of a motor car and the functions of its various parts are explained. Useful hints are given about the need for care and consideration for others in the early stages of motor driving, and attention is drawn to a problem of motor insurance which is frequently forgotten by motorists. Policies are so framed that the companies are only responsible for the replacement value of any portion of a car that is damaged in an accident. Consequently, if a car is kept for a sufficient number of years, its replacement value may become practically nil, although the insured continues, as a rule, to pay the same premium. It is true that the Medical Insurance Agency (429, Strand) has a special "doctor's policy" (underwritten at Lloyd's), under which reduced values determine the premium payable as the car grows older. But this does not meet the difficulty completely, and there seems to be no method by which the insured owner can avoid considerable expense in replacing an old car accidentally destroyed by fire. The *Autocar* is of opinion that "a very drastic revision of automobile insurance is overdue." An article on "Housing the car at home" is useful, and is illustrated with many types of garage. An extract from an account of the 1,000 miles run to Edinburgh in 1900 gives the novice some idea of his indebtedness to his forefathers, whose trials have led to the production of that perfect instrument, the modern motor car.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 231.

## An Address

ON

## FASHIONS AND FADS IN MEDICINE.\*

BY

ROBERT HUTCHISON, M.D., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL.

I REMEMBER being present many years ago in a provincial town, at the annual gathering of the British Medical Association, and at the general meeting of representatives happened to occupy a front seat in the gallery next to an old friend, a distinguished gynaecologist, since dead. After gazing down in silence for some time at the assemblage below he turned round to me and exclaimed in a tragical whisper, "The medical profession in bulk is indeed a saddening spectacle!"

Well, gentlemen, I do not know that in our exterior habit we present a more "saddening spectacle" than any other collection of human beings, but undoubtedly there are some of our intellectual habits which are calculated to make the judicious grieve, and chief amongst these is our subservience to fashions. For let there be no mistake about it, there is a fashion in the cut of the robe of Aesculapius just as much as in that of more mundane garments, and few of us altogether escape its influence.

This, of course, is no new observation. A certain Dr. Harris,† for example, writing as long ago as the middle of the eighteenth century, delivered himself upon the subject as follows: "For some different modes and customs, sometimes perhaps better, sometimes worse, come into Fashion and go out again in Physick as well as Dress; and the common Herd of Physicians too easily give credit to the Promises of new Leaders, till that faithful Mistress Experience at last shows them safer ways to Truth."

So apparently we are no worse than our predecessors after all. I thought, however, that it might be worth our while to consider together the origin of fashions and fads in medicine, and their influence for good and evil on our work, and that will be the subject of this address.

*The Nature of Fashions.*

At the outset of our inquiry we are met by the difficulty, What is meant by a "fashion"? It is not always easy to say, but I think one may regard transience as being fashion's essential characteristic. Take, for instance, the matter of hats and hearts. It would not be correct to say that it is the fashion for women to wear hats in England, for I suppose women have worn hats here ever since the Stone Age. On the other hand, it would be quite exact to speak of its being now the fashion to wear what I believe are called cloche hats. So in the case of hearts. It would not be accurate to say that it is the fashion to treat heart disease with digitalis, for that remedy has now been in use for close upon a century and a half; but it would be true, or perhaps it would have been true before the war, to say that it is the fashion to send cases of heart disease to Nauheim. Time, therefore, is the essence of the matter, and it may take time to determine whether a theory or a treatment is merely a fashion or whether it has come to stay. None the less I think there is an intuitive faculty—a sort of flair for truth—stronger in some of us, it is true, than in others, but capable to some degree of cultivation in all, which may serve as a touchstone in the matter, and which will often save us from following a will-o'-the-wisp.

Fashion may affect either our beliefs as to the nature and origin of diseases or our practice in their treatment. Fashions in belief may lead to fashions in treatment, but we also find fashionable treatments which are based on no intelligible belief. In the eighteenth century, it will be remembered, Dr. John Brown propounded his doctrine of "excitability," and divided all diseases into the "sthenic," in which excitability is in excess, and the "asthenic," in

which it is in defect. This theory became fashionable, and seeing that according to the Brunonian teaching 87 per cent. of disease is asthenic and needs stimulation, it also led to an abandonment of the then prevailing fashion of exsiccative bleeding. On the other hand, in the same century Bishop Berkeley introduced his panacea of "tar water" which also quickly became the fashion, though no pretence was made that its supposed virtues were based on any reasonable theory at all. To turn to a modern example, neurasthenia has in recent times been attributed to such different causes, amongst others, as mobility of the kidney, eye-strain, displacements of the uterus, intestinal auto-intoxication, disturbance of the "endocrine balance," and focal infection. Each of these beliefs has in its time been fashionable, and there have been corresponding fashions in treatment which have ranged from such trivial procedures as the ordering of spectacles or of fantastic diets, to more formidable measures, such as removal of all the teeth, or of the whole lower bowel. On the other hand, the use of the high-frequency current in the treatment of all manner of diseases, which was so much the fashion at the end of last century though now rather *démodé*, arose independently of any pathogenic theory.

Such, then, being the nature of fashions in medicine, we have next to ask, How do they arise? It is really very difficult to say. How do fashions arise in dress, or in art, or in games? We do not know. We can, however, recognize some modes of origin of medical fashions, and these have now to be considered.

*Origin of Fashions from Fads.*

First, fashions may arise out of fads. But this at once raises the question, What is a fad, and how does it differ from a fashion? Well, I suppose a fad is essentially an individual thing, a crochet or favourite idea held, often independently of evidence, by a single person or by a small group of persons. But sometimes the bees in the individual bonnet swarm, and then we get a fashion. A fashion, then, may be regarded as an epidemic fad. But in order that a faddist may infect others and make his fad epidemic he must be a person of some importance. You or I might wear any bizarre kind of waistcoat we pleased and no one would take any notice, but if the Prince of Wales, for instance, appears in America in an unusual garment the fashion spreads like wildfire throughout the States. It is very probable, I think, that Bishop Berkeley's tar water caught on as it did largely because he was a bishop; had he been a mere curate he would have been left to drink it alone.

It would be easy, though indiscreet, to mention contemporary examples of eminent fad-carriers who have infected large sections of the profession and so produced fashions, but everyone will be able to think of such instances for himself. Again, the faddist who is to succeed in making his fad a fashion must not only be a person of prominence; he must also be instant, both in season and especially out of season, in preaching his doctrine—as, indeed, most faddists by nature are. Reiteration is essential; he must proceed on the principle that "What I say three times is true," and he will infallibly obtain many disciples.

*The Origin of Fads.*

But all this only shifts the difficulty, for how does an individual become a faddist? As to this it may be remarked that the disease of faddery may be either congenital or acquired. To parody a familiar quotation, some are born faddy, some achieve faddery, whilst some have it thrust upon them. The congenital faddist, to take his case first, is met with in every walk of life. He is born with a kink in the brain, a natural worshipper of the idols of the cave, an optimist rather than a pessimist, credulous rather than sceptical, lacking in humour, judgement, and common sense. To quote the late Dr. Mercier, "the faddist is constitutionally incapable of weighing evidence, of suspending his judgement, or of entertaining doubts," and, as Macaulay said, he is "utterly lacking in the faculty by which a demonstrated truth is distinguished from a plausible supposition."

Others achieve faddery, and there are several ways in

\* First delivered before the Medical Society, and published in the Treatise of the Society, by John Martin, F.R.S. London, 1742.

† Counties Society.

variability in our views and practice from year to year; that we should at one time attribute most human ills to uric acid, at another to auto-intoxication, to oral sepsis, to "disturbance of the endocrine balance," or to avitaminosis; that our pathological beliefs should be dominated now by "toxins," now by "reflex action," or by "vicious circles"; that to-day we should seek to cure all manner of disease by excising the ovaries, to-morrow by removing the appendix or the teeth; one year by the injection of sea-water, another by the administration of sour milk, or by the application of violet rays; that we should pin our faith for collective salvation sometimes to "team work," and at others to "early diagnosis" or "preventive medicine"; in short, that we should be as much at the mercy of "stunts" as the yellow press, as much the slaves of catch-words as politicians, and as intellectually unstable as a popular electorate.

#### *How to Restrain the Influence of Fashion.*

Let us, then, consider how we can moderate and restrain the excessive sway of fashion in our practice and beliefs. And first it is to be noted that fortunately many of us have a natural immunity to fashions and fads. These are men with a mental make-up the very opposite of that of the congenital faddist of whom I have already spoken. They are individualists, lacking in the herd instinct; sceptical rather than dogmatic; pessimists rather than optimists, with a sense of humour and a natural instinct for truth. And the same is true of nationalities. The Scots, for instance, are, on the whole, being a humorous nation, singularly free from fads—except in the sphere of religion, though a Scottish faddist, when you meet him, is, like Barrie's Scotsman "on the make," "a fearsome spectacle." America, on the other hand, is, I suppose, the most fad-and-fashion-ridden country on the civilized globe. This is probably the combined result of defective general culture, a love of novelty as such, and too much money. It is interesting in this connexion to speculate upon the possible effect on our liability to suffer from fashions of the admission of women in large numbers to our profession. Will the woman who has not the courage to wear last year's hat have the courage to prescribe last year's drug? I do not know. We can only wait and see; perhaps I should say we can only watch—and pray.

Of course, the antifad temperament has its own drawbacks. It is possible, as was said of a very distinguished physician of the last generation, "to carry common sense to the point of a vice." The acquired scepticism of age also is not without danger. As Mark Rutherford warns us in *Deliverance*:

"A man must for ever keep himself open to the reception of new light. As he gets older, he will find that the tendency grows to admit nothing into his mind which does not corroborate something he has already believed, and that the new truth acquired is very limited. If he wishes to keep himself young he must use his utmost efforts to maintain his susceptibility. He must not converse solely with himself and turn over and over again the thoughts of the past. He must not in reading a book dwell upon those passages only which are a reflection of his own mind."

On the other hand, it is possible to have too open a mind. There are some propositions ("E.R.A." for example) of which one should be able to say, "This is certainly not true, or, if it is, it has no right to be." We are here confronted with the old difficulty of finding the *via media* and of practising that "animated moderation" which Bagehot used to praise. On the whole, perhaps, we cannot do better than follow the advice of Pope:

"Be not the first by whom the new is tried,  
Nor yet the last to lay the old aside."

#### *Effects of Education.*

It is commonly said that education is a great safeguard against quackery and faddery. I profoundly disbelieve it. So far as I can see, the higher one goes in the social scale the more does fashion in health matters prevail, and the so-called intelligentsia are the most gullible of all. It would almost seem, indeed, as if everyone has a certain stock of credulity, and the more sceptical he is in everything else the more credulous is he in matters medical.

It may be replied that this is the result of the wrong kind of education and that what is needed is more teaching of science. Again I disbelieve. If this were so the saying of Matthews Duncan would not be true—as I, for one, believe it to be—that "There are more quacks inside the profession than outside it." No; if education is to help us it must be a more humanistic education, by which I do not necessarily mean a classical training—though there is much to be said for that—but an instruction in the philosophy of a subject as opposed to its practical applications. In medicine it means especially the teaching of medical history and pathology. Sanity, humour, breadth of view, and a power of criticism are, it has been said, the marks of humanism, and the result of a humanistic education is a critical, humorous spirit with a sense of proportion, not given to extremes and with some sense of historical perspective and some logical faculty. It is that type of mind that we have to aim at shaping in our students, and that is why I profoundly regret the premature scientific specialism to which the intending doctor of to-day is perforce driven. We want, in short, more of the Hellenistic spirit, the spirit of common sense, sanity, and moderation. To quote Professor Gilbert Murray:

"If you look at a Greek statue or bas-relief, or if you read an average piece of Aristotle, you will very likely at first feel bored. Why? Because it is all so normal and truthful; so singularly free from exaggeration, paradox, violent emphasis; so destitute of those fascinating by-forms of insanity which appeal to some similar faint element of insanity in ourselves. . . . What is at the back of this sort of feeling? It is the same psychological cause that brings about the changes of fashion in art and dress; which loves 'stunts' and makes the fortunes of yellow newspapers. It is boredom or ennui. . . ."

It was this spirit of sanity which informed Greek medicine, so that, as Dr. Singer says of the physicians of the Hippocratic school—

"they remain for the most part, patient observers of fact, sceptical of the marvellous and the unverifiable, hesitating to theorize beyond the data, yet eager always to generalize from actual experience; calm, faithful, effective servants of the sick."

#### *Effects of Ridicule.*

Apart from such an education as this, a sense of humour is the best defence against fads and fashions, and ridicule is the weapon most adapted to their destruction. It has been remarked that there is no use in arguing with a prophet; you can only refuse to believe him. And so there is no use in arguing about a fad or a fashion; you can only laugh at it. If someone tells you, for example, that he is able to cure most diseases, from a common cold to cancer, by putting his patients on the diet of King Nebuchadnezzar, you can only smile. It is idle to point out to him that others—the late Dr. Salisbury, for example—cured, or claimed to cure, the like diseases by adopting the diet of Giant Pee-faw-fum. The one is fanatical about raw herbs and the other about raw meat, and reason has nothing to do with the matter. Further, I think that we tend to deal too tenderly with the crank, and that he is allowed too much rope in our medical societies, journals, and newspapers. I know that life is short, and that the same are busy men while the cranks are only busybodies, and that there are better and more amusing things to do than to waste time in confuting them; but all the same, judgement is too often allowed to go by default, with the result that faddists have to-day far more influence with the public and far more say in shaping health legislation than their importance merits. The general practitioner also should make a better stand against these things. He should be less the slave of the advertising chemist, less afraid to use his own judgement and common sense, and should not allow himself to be bluffed by faddists, however eminent. For, after all, the test of truth is in its practical results, and it is by the experience of the general practitioner that in the last resort all fads and fashions must be judged. Perhaps in the final analysis, however, the conclusion of the whole matter may be that both faddists and antifaddists are required for progress; that we must always zigzag towards our goal like a ship tacking against the wind—now going too far to the right, now to the left; that, in a word, both the "crank" and the brake are necessary for the machine.

*Fashions in Doctors.*

Finally, just as there are fashions in pathological theories and in treatments, so there are fashions in doctors. I confess, gentlemen, that I have always been puzzled to explain what makes for success in our profession. It certainly does not seem to be a question of knowledge, nor yet of manners, nor even of character or morals. But if it is difficult to account for ordinary success, it is still more difficult to explain what makes a doctor the "fashion" in his town or district—what makes him, to use an expressive Americanism—"it." We meet the same problem, of course, in other spheres. Why, for instance, of a thousand novels all alike jejune, does one become a "best seller"? Or why does such a song as (let us say) "Yes, we have no bananas" sweep a continent, when a hundred others with equally foolish words and no less catchy an air drop still-born from the lips of the music-hall comedian? "Sir," said Dr. Johnson, "it is in vain to try to explain the inscrutable."

In some cases, of course, a doctor becomes the fashion by skilful self-advertisement, "by toying," as Sir William Osler said, "with the Deilah of the press," but many a man has become the fashion *malgré lui*, and it would be a profound mistake to suppose that all fashionable practitioners are charlatans. On the contrary, many of them have been and are men of whom any profession might be proud; it will suffice, perhaps, to mention Asclepiades in Roman times and Tronchin in eighteenth century France, without referring to more modern examples. Still, one should not envy the fashionable doctor; rather should one wonder at him. He leads a life of slavery, even although, as a wag said, it is slavery on the guinea coast; and, circumstanced as he is, good and thorough work becomes impossible. His position, too, on a pinnacle is always precarious. He has, it is true, his little day, but he is apt to wake up one morning to find that his worshippers have stampeded en masse overnight to some newer shrine of the fickle goddess Fashion.

## THE EFFECT OF PITUITRIN AND INSULIN ON BLOOD SUGAR:

### THEIR ANTAGONISM AND THE MODE OF ITS ACTION.\*

BY

R. D. LAWRENCE, M.A., M.D.,  
CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL;  
AND

R. F. L. HEWLETT, M.R.C.S., L.R.C.P.,  
ASSISTANT CHEMICAL PATHOLOGIST.

RECENT work by Burn<sup>1</sup> on rabbits has clearly shown the antagonism of infundibular extracts to insulin. If given in sufficiently large doses the administration of posterior lobe extracts prevented the fall of blood sugar caused by insulin. He states that this effect is not produced by extracts of the anterior lobe or of any other tissue (except adrenaline). Nor did he find that pituitrin given alone produced such a rise in blood sugar as to account for its almost complete inhibition of insulin action. Some of the doses he used on rabbits were so large, corresponding to about 150 c.cm. for an average human adult, that it was felt that their effect might be partly toxic and at any rate did not permit of the same conclusions being drawn regarding the effect of therapeutic doses in man. Again, these results were obtained in normal rabbits and would not necessarily apply to diabetics. Accordingly the scope of this investigation has been to examine the effect of therapeutic doses of infundibular extract on the blood sugar content of normal and diabetic man, particularly as regards an insulin antagonism. Other points of interest have arisen, especially regarding the site of this antagonism, and are also included in this paper. Parke Davis 10 per cent. infundibular extract (pituitrin) has been used, and care has been taken to use the same batch of insulin. The blood sugar was estimated in duplicate by Maclean's method on blood drawn from the ear, and the

\* This investigation was carried out with the aid of a grant from the Medical Research Council.

normal persons were all students and residents at King's College Hospital, to whom our thanks are due for some rather trying experiments. Unfortunately we were not able to follow the blood sugar for as long as we wished, but this has not vitiated the results.

### Effect of Pituitrin on Blood Sugars in Normal and Diabetic Persons.

The literature is full of contradictions regarding the effect of pituitrin on blood sugar: Borchardt, Cushing, and others state that it causes a rise in blood sugar, and Franchini, Stenstrom, and others deny this. Burn found in rabbits with large doses that sometimes there was a slight rise and sometimes a slight fall. We have investigated this by giving 1 c.cm. subcutaneously to normal and diabetic persons (Tables I and II). The normal persons received their pituitrin three to four hours after breakfast when their blood sugars had returned to a fasting level, and the blood sugars were followed every half-hour for two hours. Of the six cases investigated, three showed no appreciable change—

TABLE I.—Effect of Pituitrin on Blood Sugar of Normal Fasting Individuals.

	Fasting Level.	Pituitrin Injected.	Time (Hours) after Pituitrin.			
			1/2.	1.	1 1/2.	2.

less than 10 mg. per cent.; one showed a drop of 17 mg., and two others a rise of about 20 mg. (Details of five of the six cases are given in Table I.) Consequently we can conclude that pituitrin has no appreciable effect on blood sugar, small changes probably being due to variations in the water content of the blood, as Partos and Katz-Klein<sup>2</sup> have shown. The three diabetics similarly showed no variation in blood sugar (Table II).

### Antagonism of Pituitrin to Insulin in Normal and Diabetic Persons.

Having determined the separate effect of a given dose of pituitrin and of insulin in various individuals, we next gave them simultaneously in different parts of the arm. The results (Table III) show the almost completely antagonizing

TABLE III.—Antagonism of Pituitrin to Insulin in Normal Persons.\*

effect of pituitrin on insulin. The antagonism is most marked in the first hour, for in some of the cases the insulin seemed to gain the upper hand in the second hour, and lowered the blood sugar considerably, though never so low as when insulin was given alone.

The same antagonism was clearly demonstrated in diabetics. Insulin alone was given one day to certain cases on standard conditions of diet, and on the following day 1 c.cm. of pituitrin was injected at the same time as the insulin. The blood sugar was estimated for five hours, and the results are shown in Table IV. The first entry is the

In Case B the difference before and after pituitrin is more marked if the initial levels are regarded.

fasting level; the injections were then given and breakfast followed half an hour later. Three of the cases showed the antagonism very clearly. The fourth (D) was less definite; he also had the lowest blood sugar level and was on the lowest diet. Presumably he had the least carbohydrate or glycogen store in his body, and it is likely that this is why pituitrin antagonized insulin less than in the other cases; for we will produce evidence to prove that pituitrin mobilizes glycogen and thus counteracts the action of insulin.

#### Tolerance of Normal Persons for Insulin.

Insulin had its usual effect in lowering the blood sugar of all the normal individuals investigated, and it may be interesting to record the effects of different doses. In every case the insulin was administered three hours after breakfast, when the blood was at a normal fasting level, and the fall of blood sugar was watched for two hours unless the onset of hypoglycaemia supervened before that time. Lilly insulin was used throughout the experiments, as it seemed to be more rapid in action than British.\* Doses of 10 units lowered the blood sugar slightly from 10 to 15 mg. per cent., but not sufficiently to cause symptoms of hypoglycaemia. Doses of 15 units lowered the blood sugar by from 15 to 35 mg. in different cases, but caused symptoms only once at a blood sugar level of 65 mg. at the end of one and a half hours. Half an hour later this case had recovered spontaneously without the administration of glucose and the blood sugar had risen to 75 mg. Such a recovery is a well known fact, and would indicate that the discharge of glycogen from the liver is not really inhibited by insulin, as has been stated, and that the store of glycogen is not exhausted when hypoglycaemia does occur, but merely that glycogenolysis is not able to keep pace with the rapid disappearance of sugar from the blood caused by large doses of insulin in normal individuals. Doses of 20 units caused symptoms of hypoglycaemia in both the normal cases to which it was given, but one of them recovered spontaneously and showed higher blood sugars at the end of two than of one hour. Other cases had to be given glucose by mouth, and the time required for recovery was from three to ten minutes. It was thus fairly clear that 15 to 20 units is about the limit of tolerance for normal individuals in the fasting condition.

Another point of interest was to determine the tolerance for insulin of a normal individual on a normal diet. A brave volunteer having been obtained, he was given increasing doses of insulin before breakfast on successive days until symptoms appeared. Blood sugar tests were not

carried out, for it had already been determined that symptoms appeared in his case at about 75 mg. per cent. Two doses a day were not given, both on account of the inconvenience of such a procedure and to avoid depleting his glycogen store. It is assumed that the latter is not likely to be much exhausted by one dose a day, whereas two large doses a day might very well deplete it, so that he would tolerate less insulin as the experiment went on. On each day his breakfast consisted of about 60 grams of carbohydrate, 20 to 30 of protein and fat, and the dose of insulin was increased by 10 units every day. A dose of 40 units was tolerated without any effects, but 45 units of A.B. insulin produced quite severe symptoms about three hours after breakfast. Unfortunately the subject had grown careless about insulin, forgotten all about his injection, and was just setting out on a walk unarmed with sugar when symptoms of weakness, dizziness, and faintness came on suddenly. He managed to reach a coffee shop, and without unnecessary explanations ate a quarter of a pound of toffee and was restored in a quarter of an hour. It seems likely that if he had had some carbohydrate two hours after his insulin the symptoms would never have occurred, and that the normal individual could tolerate over 100 units a day, perhaps far more, if supplied frequently with a large amount of carbohydrate to cover it. While insulin is actually balanced by the active absorption of carbohydrate, no hypoglycaemia occurs.

This experiment tells us little or nothing definite about the effect of an injection of insulin on the production of endogenous insulin, but it is probable that the latter was produced as usual under the stimulus of carbohydrate food. For if no, or little, endogenous insulin had been produced, as in diabetes, we imagine that the carbohydrate of his breakfast and of his glycogen store would have been sufficient to balance 45 units of insulin. This individual tolerated 20 units in the fasting condition with the appearance of only slight symptoms which did not require the administration of glucose to effect recovery.

#### Certain Symptoms due to Pituitrin.

All the normal individuals who received a therapeutic dose of 1 c.cm. of pituitrin developed unusual and alarming symptoms which we have not found described elsewhere.\* From ten to thirty minutes after the hypodermic injection they became a ghastly pale grey colour, and some of them became dizzy, faint, and shaky. This appeared to be due to marked vaso-constriction of the cutaneous and probably of the cerebral vessels. The pulse was not quickened nor was the blood pressure raised. This latter point was confirmed in two cases by the sphygmomanometer, but in the others was merely a clinical impression of the pulse. Fortunately their appearance was more terrifying than their feelings, and the pallor and other symptoms usually passed off by the end of an hour. Now, widely as pituitrin is used in obstetrics, etc., it does not seem to have the above effect, and a few cases which we have recently observed closely (and personally) have not shown even pallor. Both normal men and women have shown these symptoms, but they have been absent in the five diabetics tested. Accordingly, it is not likely to be due to some unusual toxic product, such as histamine, of the special batch of pituitrin used. Moreover, one of our cases of diabetes insipidus who is constantly on the drug nearly always notices this effect if he takes more than 0.5 c.cm. This apparent difference in action of pituitrin on normal persons, diabetics, and women in labour offers an interesting field for confirmation and further investigation. We have no explanatory hypothesis to offer.

#### Blood Sugar Curves in a Case of Diabetes Insipidus.

Before we attempt to discuss the relation of the pituitrin-insulin antagonism to the wider questions of glycolytic function and carbohydrate metabolism in general some other experiments bearing on the subject will be recorded. It is well known that a lowered carbohydrate tolerance is associated with hyperpituitarism (acromegaly) and a raised tolerance with hypopituitarism (Fröhlich's syndrome, etc.). These diseases are commonly supposed to be associated with disturbance of the anterior lobe of the pituitary

\* British insulin has recently become quicker in its action.

\* Since this was written similar effects have been described by B. Sacks (*Heart*, vol. xi, No. 4, December, 1924.)

gland which affects carbohydrate metabolism. But it is the posterior lobe, or at least extracts from it, that affect insulin action. Also the carbohydrate metabolism is affected in the following case of diabetes insipidus, although the condition is commonly held to be due to deficiency of the posterior lobe alone. Therefore it would appear that the posterior lobe as well as the anterior is concerned with carbohydrate metabolism.

A young man developed intense diuresis at the end of the war as the result of cerebral malaria contracted in East Africa. It is controlled by pituitrin injections. He also shows evidence of involvement of the anterior lobe in having lost his pubic hair and becoming impotent. His blood sugar curves after 50 grams of glucose given fasting are shown in Table V. In one he had

TABLE V.—Effect of Glucose Meal on Case of Diabetes Insipidus with and without Pituitrin.

had no pituitrin for twenty-four hours, and in the other was given 0.75 c.cm. of pituitrin a quarter of an hour before the test. Without pituitrin he shows an abnormally high tolerance for glucose. Indeed, his curve descends from the fasting level instead of rising. With pituitrin, although the tolerance is still high, there is a very definite difference and the curve is an ascending one. This is seen both in the arterial and venous blood sugar, and in the difference between the two, which is greater without pituitrin.

This arterio-venous difference is absent or very slight in diabetes, and we lay considerable stress on it as an indication of the powers of the muscles to store sugar and abstract it from the blood.<sup>3</sup> We presume that it is an index of glycogen synthesis in general, and that the glycogenic function of the liver runs parallel with that of the muscles. We look upon these curves as further evidence that pituitrin lowers the assimilation power for carbohydrate, interferes with the glycogenic function, and perhaps actually causes glycogenolysis.

#### Mode of Action of the Pituitrin-Insulin Antagonism.

The action of insulin on blood sugar and glycogen stores is little enough understood, but the effect of pituitrin is still more obscure. It is known that pituitrin inhibits the glycogenolysis of adrenaline and anaesthetics, and therefore, when it antagonizes insulin, it hardly seemed likely that it does so by stimulating glycogenolysis. To determine the latter point more definitely, we have taken advantage of the well known action of ergotamine in paralysing the sympathetic and preventing glycogenolysis. Ergotamine prevents adrenaline hyperglycaemia and also enhances the action of insulin in lowering blood sugar by inhibiting the mobilization of sugar from the glycogen of the liver. Therefore we have investigated the pituitrin-insulin antagonism on rabbits under the influence of ergotamine tartrate. In the first group of experiments blood was obtained from the ear veins, but this was found so difficult in ergotaminized rabbits that blood was obtained by heart puncture in all the latter experiments. The same rabbit was used for all the experiments.

The results of the first group of experiments is given in Table VI and Fig. 1. In Experiment A, 5 mg. of ergotamine was given intravenously to a normal rabbit who had received no food for eighteen hours. Two hours later 3 units of insulin (Lilly) were given subcutaneously and the blood sugars followed until they had fallen from 112 to

58 mg. per cent. at the end of one hour. Then 1 c.cm. of pituitrin was administered and found to have no antagonizing effect on insulin, as the blood sugar steadily dropped during the next hour. Macleod, Banting, and Burn have shown that, without ergotamine, pituitrin always causes a rise of blood sugar at this stage.<sup>1</sup> Symptoms of hypoglycaemia appeared, requiring the administration of glucose, and the animal did not fully recover for another hour.

The same experiment was repeated fourteen days later with identical doses of pituitrin and insulin, but without ergotamine (Experiment B). The antagonism of pituitrin was clear but did not last long and was not complete, as the dose of insulin was too great to be entirely balanced by 1 c.cm. of pituitrin. No symptoms of hypoglycaemia appeared. On a subsequent day the same dose of insulin was given alone (Experiment C). The blood sugar fell steadily, but not to such a low level as when ergotamine was given, a well known phenomenon.

These experiments seemed to show that ergotamine abolished the antagonism of pituitrin for insulin. This was confirmed in another way with smaller doses of insulin (Table VII, Fig. 2). In Experiment A, 1 1/2 units were given alone, and this proved to be a dose which caused a moderate fall of blood sugar which was followed later by a spontaneous rise. In a second day's experiment (B) 1 c.cm. of pituitrin was given along with insulin. The antagonism of pituitrin was clear and a slight rise of blood sugar occurred, to be followed by a fall when the pituitrin action became enfeebled, as it usually is after one hour. On a third day's experiment (C) 5 mg. of ergotamine was given, and two hours later the same dose of pituitrin and insulin. At first the pituitrin antagonized the insulin, but later the blood sugar fell to a lower level than in B, as always happens when ergotamine has been given to inhibit glycogenolysis. Experiment C was contrary to what was expected, and contradictory to the results obtained in Table VI. But it was felt that the preliminary rise in blood sugar might simply have been caused by the pituitrin

FIG. 2.—For description see text and Table VII.

coming into action more rapidly than insulin and producing the initial rise in blood sugar which is the common effect on most rabbits; or, more likely still, that the ergotamine had not yet fully paralysed the sympathetic. Accordingly in Experiment D a second dose of pituitrin was given two hours after the first, when the blood sugar had fallen to a much lower level and there was no doubt that the action of ergotamine was fully established. This second dose of pituitrin had no effect in antagonizing insulin, and the blood sugar continued to fall in the third hour and slight symptoms of hypoglycaemia appeared. Without ergotamine Banting, Macleod, and Burn have shown that an injection of pituitrin invariably abolishes the insulin hypoglycaemia and raises the blood sugar as quickly as an injection of glucose itself.

It seems quite clear from these experiments that ergotamine abolishes the antagonism of pituitrin to insulin.

#### Evidence that Pituitrin can Cause Glycogenolysis and Reduced Carbohydrate Tolerance.

The above experiments with ergotamine show that this drug abolishes the usual antagonism of pituitrin to insulin. Since ergotamine acts by paralysing the sympathetic and preventing glycogenolysis, we can conclude that pituitrin counteracts insulin by mobilizing sugar from the glycogen of the liver or muscles or both. We look upon the experiment on the diabetic (Case D, Table IV) as affording confirmatory evidence of this. His carbohydrate diet, his blood sugars, and hence his glycogen and carbohydrate stores, were lower than in the other diabetics, and pituitrin antagonized insulin only very slightly. We look upon him as being in much the same condition as an ergotaminized rabbit—that is, unable to mobilize glycogen because he had none in store. The experiment on the case of diabetes insipidus points to the same thing. When he was deficient in pituitrin his carbohydrate tolerance and his power of storing glycogen were very high. After a dose of pituitrin his carbohydrate tolerance, though still very high, was definitely less. It was not possible to try the effect of a large dose of pituitrin on his blood sugar curve because he

developed these curious symptoms already described even with a small dose of 0.75 c.cm.

The clinical evidence of disease due to an enlarged and overactive pituitary gland is of the same nature. In acromegaly the blood sugars are commonly raised, the carbohydrate tolerance reduced, and we may presume that glycogenolysis is excessive. At first the fasting blood sugar is normal, but later all the features of a true diabetes mellitus may develop, presumably by prolonged overstrain of the pancreas. Certainly, it is the anterior lobe which is supposed to be especially affected in acromegaly, and which has been looked upon as influencing carbohydrate metabolism. But it seems clear from our experiments that posterior lobe extracts (pituitrin) do affect carbohydrate metabolism. No clear separation of the functions of the two parts of the gland can be made with our present knowledge.

#### Evidence that Lack of Pituitrin Causes Excessive Glycogen Synthesis.

The only evidence we have been able to produce of this is the very high carbohydrate tolerance of the above case of diabetes insipidus. But in addition it is generally accepted that deficiency disease of the pituitary, Fröhlich's syndrome, etc., is accompanied by a markedly increased carbohydrate tolerance.

#### Evidence that Pituitrin can Prevent Glycogenolysis.

Although this is directly contrary to the action of pituitrin already described, there is clear evidence that it can act in this way. Stenstrom<sup>1</sup> was the first to show that large doses of pituitrin inhibit the hyperglycaemia and glycogenolysis caused by adrenaline and anaesthetics. This has been confirmed by Burn and others. Similar evidence is afforded by some observations of Falta<sup>4</sup> on the effect of adrenalin on the glycosuria of acromegaly. He records two cases in which the patients showed abundant glycosuria after carbohydrate food, but an injection of adrenalin failed to produce any glycosuria.

There is evidence to suggest that when insulin hypoglycaemia is proceeding too far, recovery is aided by an increased production and liberation of adrenaline in the body, which causes a mobilization of glycogen and a rise in blood sugar concentration. In view of Stenstrom's experiments it does not seem likely that when pituitrin antagonizes insulin it does so by calling this protective adrenalin into play.

From all the above evidence it seems that pituitrin plays a complicated part in the regulation of blood sugar and carbohydrate metabolism. It seems to have a balancing action on carbohydrate metabolism and inhibits the action of drugs which tend to change the blood sugar concentration away from normal in either direction. It controls both the hypoglycaemia of insulin and the hyperglycaemia of adrenaline, but it effects no appreciable change on a normal blood sugar concentration.

#### The Similar Effects of Thyroid and Pituitary on Carbohydrate Metabolism.

It is interesting to note the great similarity of action of these two glands and their extracts, both experimentally and in the clinical evidence of disease. Both have marked effects on total metabolism as judged by the basal metabolic rate, which is increased or diminished respectively by excess or deficiency of both glands. Thyroid feeding in animals empties the glycogen store, raises the blood sugar, and inhibits insulin action to a marked extent.<sup>5</sup> In hyperthyroidism (Graves's disease) we commonly find raised blood sugars and diminished carbohydrate tolerance, as shown by the response to a glucose meal. As already pointed out by one of us in another publication,<sup>6</sup> it is very common to find a very low fasting respiratory quotient, which is taken as evidence that the carbohydrate stores of the body are deficient and the body is drawing on protein and fat. The power to oxidize carbohydrate is not defective, for the respiratory quotient rises very high after a carbohydrate meal in these hyperthyroid cases. The clinical picture of hypothyroidism and hypopituitarism is also very similar. Indeed, all the metabolic features of excess and deficiency disease of the two glands are almost the same, and we are

inclined to attribute them primarily to the disturbance of carbohydrate metabolism, and especially to the upset of normal glycogenic function. Many investigators have pointed out effects that disease and extirpation of the thyroid have on the morphology of the pituitary gland, and vice versa, but no constant changes have so far been established.

#### *Does Insulin Antagonize Pituitrin?*

There is no clear evidence on this point. We have been struck with the tendency common in diabetics on insulin treatment to become obese on very low diets, sometimes less than 20 calories per kilogram of body weight, but it is rather drawing a bow at a venture to attribute this to inhibition of normal pituitary function. We have heard, however, of a male insulin case who is developing more definite symptoms of hypopituitarism—deposition of excessive fat round the abdomen and buttocks and the loss of pubic hair. We have unfortunately not been able to get in close touch with the case up to the present. The similarity of the appearance of many insulin cases to that of hypopituitarism was noted early by several clinicians in America.

One of us has produced evidence that insulin has a remarkable effect in controlling and ameliorating certain cases of Graves's disease,<sup>6</sup> and other investigators have observed the same effect. In the same way we believe that insulin might affect acromegaly favourably and prove useful in its treatment, but so far we have not had a suitable case of active acromegaly on which to try it.

#### *Conclusions as to the Effect of the Pituitary on Carbohydrate Metabolism.*

Any conclusions we draw are put forward very tentatively. It would seem that the pituitary has a powerful stabilizing influence on blood sugar and carbohydrate metabolism. There are two well recognized mechanisms which control and affect blood sugar concentration. The first is the mechanism which produces varying amounts of endogenous insulin to keep the blood sugar normal by balancing the carbohydrate of the food. It is clearly anabolic in function. The second is the immediate action of adrenaline in raising the blood sugar by mobilizing glycogen to meet any extraordinary needs of the individual for sugar. This mechanism is clearly katabolic. Pituitrin has no definite immediate action on blood sugar, but it controls and compensates the excessive action of the other two substances, tending to keep the blood sugar normal and at an optimum for the individual. These are the facts. But the explanation of how pituitrin can at one time stimulate glycogenolysis and at another inhibit it, as it appears to do, remains a complete mystery. It may be dangerous to deduce the normal action of an internal gland from the effects produced by its extracts, but where the pituitary is concerned the evidence of disease points to the same conclusions. We would suggest that in normal metabolism the pituitary gland, like the thyroid, maintains a balance between anabolism and katabolism. When the gland is upset in either direction an unbalanced condition of metabolism follows, and the first manifestation of this, perhaps the primary cause of all the other metabolic changes, is the upset of the glycogenic regulation of carbohydrate stores and blood sugar concentration.

#### SUMMARY.

1. Subcutaneous injection of therapeutic doses of 1 c.cm. of posterior lobe extract (pituitrin) have no appreciable or constant effect on blood sugar concentration in normal and diabetic individuals.
2. These doses markedly antagonize the effect of insulin on blood sugar, both in normal persons and diabetics. Experiments with ergotamine show that this antagonism is produced by the mobilization of glucose by pituitrin.
3. The insulin tolerance of normal individuals in the fasting condition is about 15 to 20 units. Much more can be tolerated when insulin is balanced with food.
4. Curious symptoms caused by therapeutic doses of pituitrin in normal individuals are described.

5. Blood sugar experiments on a case of diabetes insipidus are described and their significance is discussed.

6. It is suggested that the pituitary gland, like the thyroid, is one of the most important factors in producing a normal balance between anabolism and katabolism and does so primarily by its effect on glycogenic function and carbohydrate metabolism.

## ON THE TREATMENT OF CONVERGENT CONCOMITANT SQUINT.

BY

A. FREELAND FERGUS, M.D., F.R.F.P.S.G., LL.D.,  
CONSULTING SURGEON, GLASGOW EYE INFIRMARY.

SINCE the meeting of the International Ophthalmic Congress in Edinburgh in 1883 I have always adopted, as a general plan of operative procedure, advancement instead of tenotomy, and on more than one occasion I have ventured to say that tenotomy in ordinary circumstances amounts to malpraxis. It is certainly to Dr. E. Landolt that we owe this changed point of view. Forty years ago he pointed out, in numerous writings and later in a small monograph on the muscles of the eyeballs, the unreasonableness of tenotomy. Strabismus does not depend on overaction of the convergence, but on a defect in the action of the external recti muscles, due no doubt to a fault in the innervation. Landolt has conclusively shown that there is no overaction of the internal recti—that the error is one of impaired latent divergence.

The definition I always gave to the students who attended my instruction was: When the axes of vision do not intersect at the point of fixation, then there is squint. This definition includes all possible cases of squint, and, when properly interpreted, includes also the various forms of heterophoria.

In concomitant convergent squint the axes intersect, if they are in the same horizontal plane, at some point nearer than the point of fixation. If they are not in the same horizontal plane they cross each other somewhere nearer than the point of fixation. One of the characteristics of the variety of squint under consideration is that for almost any point of distant fixation within the field of vision the angle between the two axes is a constant; thereby differing materially from the forms of squint due to muscular paralysis and from those other cases in which the movement of one of the eyes is impaired by the presence of an orbital growth.

Treatment of convergent concomitant strabismus as it occurs in young children has a twofold object—namely, (a) the functional development of the squinting eye both as regards visual acuteness and as regards binocular vision; (b) the removal of an obvious disfigurement.

To a considerable extent treatment should be determined by the age of the patient and the time which has been allowed to pass from the first appearance of the squint. When the condition supervenes in early childhood, say before the patient attains 3 years of age, immediate treatment is urgently required, for if the eye be allowed to squint for a considerable time amblyopia is definitely and permanently established. The delay of a few months inevitably means that the eye is rendered permanently amblyopic. Such patients form an important group which should receive very special attention.

If the onset of true strabismus does not take place till the fifth year or later, it is generally found, if the eyes be otherwise healthy, that each eye is possessed of good visual acuteness. The cases forming this group are few; they border very closely on esophoria, and treatment has

for its object the establishment or restoration of binocular vision, and sometimes, although infrequently, the removal of a disfigurement.

In addition to these two well defined groups, a third must be mentioned. Sometimes, even in cases in which the defect has begun in the first years of life, each eye is found to have excellent visual acuteness. I have always found that from its onset the strabismus has in such cases been alternating. At times the young patient was seen to be using the right eye for fixation and at other times the left. When that has been the case the function of each eye has been developed, and in each the vision is satisfactory. The treatment applicable here is precisely the same as for the second of the above mentioned groups (alternating convergent strabismus).

The first class of cases is of extreme importance, for, if there be any carelessness in treatment, permanent amblyopia will be established and the value of the eye will be very much reduced. In my opinion the first essential is to cause the young patient to use the squinting eye for general fixation. If this be done its function will become developed, and it will become and remain a good eye. The best method of accomplishing this is to throw the non-squinting eye out of action by mydriasis, so that the small child is compelled to use the squinting eye for fixation. As a rule it suffices to place a few drops of a 1 per cent. solution of atropine sulphate in the conjunctival sac of the non-squinting eye once every second day. When this treatment is followed for some time it is found that the little patient now uses the eye which originally was the squinting eye for purposes of fixation, and that the other eye, which at first was straight, is apparently affected with strabismus.

When the fixation changes from one eye to the other I always feel satisfied, for then I am sure that the function of the eye is developing and that ultimately both eyes will be possessed of good visual acuteness. After the change has taken place I continue the same treatment for a month or even six weeks so as to establish the function of fixation in the eye which at first appeared to be the one affected. Sometimes, although rarely, this treatment suffices to remove the squint, so that both eyes appear to be used for fixation. In the majority of cases, however, at the end of the time indicated, the eye which originally deviated, and which will henceforth be called the eye A, is used for fixation; whilst the other, which hereafter will be called the eye B, deviates inwards, and that to the same extent that A did when the patient was first seen. There is now the fear that the functional development of the eye B will be arrested and that it may become permanently amblyopic. The treatment is therefore reversed and the mydriatic is applied to the eye A and is so applied till the eye B again becomes straight. When this takes place the eye A may remain straight; if it does the mydriatic should be used to A very sparingly, perhaps only once in ten days, and should be stopped altogether if the eyes remain apparently without convergence for distant fixation.

So long as there is any convergence I use the mydriatic alternately in the manner described, and thus ultimately secure the functional development of each eye, and get in each good visual acuteness. The use of mydriatics is much to be preferred to the covering of one eye with a pad or a bandage, for if the child be not under the care of a trustworthy nurse it will remove the covering altogether. A bandage is too insecure unless it be carefully attended to by a competent nurse. The primary essential in the treatment of a young child afflicted with squint is to secure the development of good visual acuteness in each eye. If that be not accomplished then unilateral amblyopia becomes established and the affected eye is permanently impaired as an organ of vision.

After the originally squinting eye, A, becomes the eye used for fixation I allow it to be used for that purpose for at least a month or even for two months, although B is convergent for distant fixation. At the end of that time I begin to use the mydriatic to A till B becomes the fixing eye, and thus alternate the use of the mydriatic for a year or a year and a half unless in the meantime the strabismus has disappeared. Again, I say that at this stage

the primary object is the development of visual acuteness in each eye.

Spectacles should be prescribed as soon as possible. In very young children errors of refraction cannot be measured with any degree of accuracy, and in addition glasses cannot be worn. This is not so serious a matter as might be thought. Clinical experience daily shows that children or even young adults who have never suffered from strabismus may have a very considerable amount of uncorrected hypermetropia and at the same time have excellent visual acuteness. The uncorrected defect has not in such circumstances prevented the development of good acuity. It is not uncommon to find children with 3 or 4 diopters of hypermetropia who nevertheless have standard vision when tested either by the types of Snellen or of Landolt. I have known a lad 16 years of age with 5 diopters of hypermetropia and full acuteness of vision in each eye. So long as an individual has a range of accommodation sufficient to correct the hypermetropic error such a result need cause no surprise.

For these reasons I delay ordering correcting glasses till measurements can be made with some approximation to accuracy and till the patient is sufficiently advanced as to be able to wear glasses. So long as I know that each eye is possessed of good visual acuteness—a function which is never lost—I am in no hurry to prescribe glasses till it can be done in a satisfactory manner.

Similar considerations determine for me the question of operation. If each eye has by the treatment here described obtained good vision, there is no particular hurry. Such vision is permanent unless some other untoward event occur. If permanent amblyopia is established in one eye, or is in the process of making, it is not likely that any operation will be a remedy. My own experience may be unfortunate, but I have not found that operation for convergent strabismus is successful in such circumstances. Within a few weeks of the operation the deviation will be found to have returned. It is quite different, however, when each eye is possessed of good visual acuteness and the patient has attained such an age as to be capable of receiving benefit from orthoptic treatment.

Probably the best apparatus for orthoptic treatment is the very ingenious amblyoscope devised by Mr. Claud Worth. There are numerous pictures suitable for stereoscopic combination, all well arranged and suitable for the purpose; but of these, two sets are of special interest. The first consists of a parrot in front of one eye and a cage in front of the other. The young patient is first of all exercised in seeing the parrot and the cage simultaneously. As soon as that is accomplished the patient is directed to adjust the instrument so as to bring the parrot into the cage. This simple exercise must be continued for some days till the result is obtained without any difficulty. To ease the monotony of the process, some of the other designs sent with the instrument can be substituted. These exercises do not to any extent promote the awakening of the function of perspective, at least not so well as the two which I consider of special value for this purpose. In these there is placed before each eye two circles which are not, as seen singly, concentric nor of the same size. On each side the larger circle contains the smaller eccentric circle. When seen with the amblyoscope the original four circles (two before each eye) become blended into two—namely, a larger outer circle and a smaller inner circle. In addition they are now found to be quite concentric and the smaller to appear either nearer to or farther away from the observer than the larger.

When the patient has reached such an age as to be capable of this training, then, if it be necessary, operation should be performed, preferably by double advancement as recommended by Landolt. As soon as possible after the operation the patient, wearing his correction for any existing ametropia, should resume the exercises with the amblyoscope.

If the concomitant convergent squint does not set in till the age of 5 or 6, or if in earlier life the affection has been alternating, then each eye is found to be possessed of good visual acuteness. Here all that is necessary is to advance each external rectus and to begin training with Mr. Worth's amblyoscope or other reliable form of stereoscope.

## HYPOGLYCAEMIA: WITH NOTES ON TWO CASES.

BY

H. S. PEMBERTON, M.B., M.R.C.P.,

PHYSICIAN TO THE DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL;  
CONSULTING PHYSICIAN, LIVERPOOL CANCER AND SKIN HOSPITAL.

THE sinking of the blood sugar level to a point at which symptoms appear may contribute to the clinical features of disease more largely than has perhaps been recognized. Whether hypoglycaemia denotes merely a fall below the normal fasting level or a fall associated with characteristic symptoms, it certainly occurs in many morbid or experimental conditions, some of which are set out below. It is of interest to speculate upon what part such a state plays in the symptomatology of the clinical counterparts to some of these conditions—for example, in Addison's disease or choleraemia. An examination of the literature makes it clear that hypoglycaemia may be associated with many diverse conditions, which I have attempted to classify as follows:

1. Hypoglycaemia follows the hyperglycaemia induced by glucose, fructose, galactose, starch, and adrenalin (Liefman and Stern,<sup>1</sup> Maclean and de Vesselow,<sup>2</sup> Frank,<sup>3</sup> Foster<sup>4</sup>), but not after the hyperglycaemia of ether, which appears to be maintained (Pemberton and Cunningham<sup>5</sup>).
2. It also occurs in many lesions of the liver: such as removal in dogs (Mann and Magath<sup>6</sup>); parenchymatous changes caused by chloroform, salvarsan, and the fungus *Agaricus bulbosus* (Steinbrink<sup>7</sup>), by phosphorus (Frank and Isaac<sup>8</sup>), and by hydrazine (Underhill<sup>9</sup>), and in the presumed circulatory changes which follow the intravenous injection of albumos and peptone in dogs (McGuigan and Ross<sup>10</sup>). In comment upon the statements of Steinbrink, it may be pointed out that in the toxic jaundice of isophilitic treatment (arsenobenzol) Bailey<sup>11</sup> found a normal fasting blood sugar; further, anaesthetic use of chloroform is accompanied by hyperglycaemia.

3. It may follow high section of the cord or sections of the nervous connexions of the adrenals (Falta<sup>12</sup>).

4. Various adrenal lesions are associated with hypoglycaemia: complete removal (Biery and Malloizel<sup>13</sup>); adrenal insufficiency (Mayer<sup>14</sup>); Addison's disease (Forges<sup>15</sup>).

5. It may occur in various states: such as alkalosis (Cambridge and Howard<sup>16</sup>); hypocalcaemia (Underhill,<sup>18</sup> Cambridge and Howard<sup>19</sup>); following the intravenous injection of sodium bicarbonate, which also decreases adrenalin<sup>20</sup> hyperglycaemia (Underhill<sup>20</sup>).

6. Lastly, there are insulin and the insulin-like substances, all of which can produce hypoglycaemia. The insulin-like substances have been derived from clams, the cortical layer of oats, potatoes, rice, wheat, beet, and celery<sup>21</sup>; and recently Rubin and Corbett<sup>22</sup> have succeeded in separating the hypoglycaemia-producing principles from the hyperglycaemia-producing principles in cabbage, lettuce, celery, and spinach.

The symptoms of hypoglycaemia occur at varying levels of the blood sugar, so that the same level in different animals and individuals may be associated with different features. In dogs, Mann and Magath<sup>6</sup> produced hypoglycaemic symptoms when the blood sugar had fallen to 45 mg. per cent. as a result of removal of the liver; in man, Banting, Campbell, and Fletcher<sup>23</sup> record a blood sugar of 52 mg. per cent., which was followed by uncontrollable hunger; Sevringhaus, Kirk, and Heath<sup>24</sup> state that symptoms appear at concentrations of 40 to 65 mg. per cent.; according to Macleod,<sup>25</sup> when the blood sugar reaches 75 mg. per cent. the patient experiences extreme hunger and a sense of fatigue; whilst in the case recorded below the venous blood sugar reached 48 mg. per cent. (and may possibly have fallen lower) without any marked symptoms being produced.

The fall in blood sugar, in causing symptoms which vary from slight vasomotor effects to convulsions comparable to those of toxic states, would appear to operate primarily upon pontine or medullary centres. Olmsted and Logan<sup>26</sup> found no symptoms in spinal cats even when the blood sugar had fallen below the convulsive level; whereas in decerebrate animals typical symptoms developed provided that the pituitary body had been removed. Dickson and others<sup>27</sup> suggest that, in insulin hypoglycaemia, abnormal metabolites appear; these bodies require oxidation, and thereby the respiratory centre is stimulated; they ascribe the muscular twitchings to cerebellar or mid-brain stimulation.

The symptoms of hypoglycaemia quickly disappear when

the blood sugar again rises. Among substances which cause this rise Noblo and Macleod<sup>28</sup> regard glucose as pre-eminent; other sugars, such as mannose, galactose, and laevulose, have a certain value, whilst the pentoses, cane-sugar, and lactose appear to be inert. Adrenalin would appear to act as a physiological antagonist in cases of insulin hypoglycaemia, whilst in other cases its antidoting action is probably due directly to glycogenolysis; so that its effect will vary according to the amount of glycogen present in the liver and muscles. In hypoglycaemic states, with mild symptoms the polysaccharides themselves appear to be efficient, whilst in severe cases with convulsions all known antidoting agents seem to lose some of their usual potency. This statement may perhaps be illustrated by a description of two cases, one mild and one severe.

The first case was experimentally induced in a normal man by fasting for five hours, feeding with glucose, and then, just as the normal

hyperglycaemic curve was beginning to fall, exhibiting insulin. The lowest recorded level of blood sugar was 48 mg. per cent. (see chart), but as the preliminary vasomotor symptoms began before this, the level may have sunk lower still. Among the symptoms and signs infra-orbital oedema was of interest; it is perhaps comparable to similar oedema observed in anaphylactic states and in one case of presumed adrenal insufficiency. The hunger, which all observers record, may be similar to that of hyperglycaemia, inasmuch as in both states the tissues would appear to be starved of glucose. Shortly after the last estimation of blood sugar a meal of bread and jam was taken; all the symptoms quickly disappeared, only to reappear an hour later in a milder form. This latter observation has also been made by Sevringhaus, Kirk, and Heath,<sup>24</sup> and would appear to be due to a secondary hypoglycaemia following a hyperglycaemia of the type recorded above. The second case, which was fatal, occurred in a man, aged 30, suffering from diabetes mellitus, who had been under my observation for two years; he also had pulmonary tuberculosis.

He was readmitted to hospital on March 29th, 1924, in a very poor condition—16 per cent. of glucose in his urine, a blood sugar of 0.357 mg. per cent., marked acidosis, and weighing 91 lb. As the table given below shows, a very definite improvement was obtained by April 4th, and on April 5th his diet and insulin dosage were both increased. On the night of April 6th, however, he became rigid with a marked opisthotonos, which lasted five minutes, after which he vomited; his temperature rose to 101° F. He was given 2 oz. of glucose by the mouth, after which he went to sleep. No more insulin was given, but his carbohydrate intake was again increased. On April 7th he was quiet, but early on the morning of April 8th he again became excited and threw his pillows about; 10 c.c.m. of 5 per cent. glucose were given intravenously and glucose feeding by mouth was attempted; adrenalin was given hypodermically in 0.5 c.c.m. doses every hour. By 8.45 a.m. he was in a flaccid, semi-comatose condition, temperature 100.6°, pulse 72, respirations 20; his skin was clammy, the eyeballs showed a pendular movement, and the corneal and abdominal reflexes were absent; the knee-jerks were present, and he exhibited double ankle clonus and plantar reflexes of the extensor type. Blood taken at 11.30 a.m. contained 27 mg. per cent. of glucose. At 1.15 p.m. the pulse was 108, and although the pendular movements of the eyeballs had ceased, ankle clonus and extensor toe were still present. He died a few minutes later.

Day.	Diet.	Blood Sugar.	CO <sub>2</sub> (vols. per cent.).	Insulin.
April 2	Protein ... 60 grams Fat ... 30 .. Carbohydrate 15 ..	0.143 mg. per cent.	57	0.5 c.cm.
April 4	—	0.093 mg. per cent.	51	0.5 c.cm.
April 5	Protein ... 90 grams Fat ... 60 .. Carbohydrate 30 ..	—	—	1 c.cm.
April 7	—	—	—	None.
April 8	—	0.027 mg. per cent.	54	None.

No post-mortem examination was possible until the next day, when the following changes were found.

**Lungs.**—The right lung was studded with caseous tuberculous masses, some an inch in diameter. There were pleural adhesions at both apices.

**Heart.**—Weight 7 oz. No microscopic changes were seen.

**Liver and Pancreas.**—No naked-eye changes were seen, but subsequent microscopic examination of the pancreas showed extensive fibrosis in which no islet tissue was visible. Other ductless glands showed no changes.

**Glycogen Contents.**—The amount of glycogen was determined in the heart, liver, and muscles by Pflüger's method rather more than twelve hours after death had taken place. Considering the glycogenolysis that must have taken place in this time and the fact that he was a severe diabetic, the figures of 0.014 per cent. for muscle, of 0.028 per cent. for myocardium, and of 0.04 per cent. for liver are perhaps suggestive of what happens to circulating glucose in insulin hypoglycaemia.

**Brain.**—This was definitely "wet"; the pia mater showed areas of milkiness, but there was no evidence of basal meningitis.

In making this record of the two cases I am greatly indebted to my colleague, Dr. L. Cunningham, with whom all the biochemical work was done; also to my late house-physician, Dr. A. J. Hurre, who made many of the observations in the fatal case.

## CONGENITAL CYSTIC DISEASE OF THE LUNGS.

BY

SYDNEY SMITH, M.D., D.P.H.,

- PRINCIPAL MEDICO-LEGAL EXPERT, EGYPTIAN GOVERNMENT.

A NEWLY born child was found dead in circumstances which suggested infanticide, and was submitted to me for examination.

The body was that of a child of about eight months' intrauterine age. It was free from marks of violence. Both lungs were in an apparently foetal condition and sank on being placed in water; both were in a state of advanced cystic degeneration (Fig. 1).

Cysts varying in size from a pea to the head of a pin were distributed throughout the whole of the lung tissue. The larger cysts were found towards the free surface. A number of cysts abutted on the pleura, but there were no pleural adhesions.

On microscopic examination no air cells or vesicles could be made out, the lungs being composed of unexpanded tissue and cysts. The cysts were smooth-walled and lined in certain cases with flattened cells. There was no trace of cubical epithelium lining the cavities nor of muscular or elastic fibres in the walls. Here and there the cavities were filled with a mucoid or colloid-looking material. Numbers of microscopic cysts could be observed immediately under the pleural surface. Numerous bronchi were seen filled with cast-off cubical and cylindrical epithelium and other debris. A certain amount of cellular infiltration could be observed around the bronchi and there were numerous small haemorrhagic foci in the lung tissue.

Cystic degeneration in both lungs of a newly born child is very rare, and the reason for its occurrence is rather obscure. Bronchiectasis occurring after birth is usually

attributed to weakening of the walls of the bronchi by disease, whereby they are unable to resist the air pressure in fits of coughing. Barty King considers that pleural adhesions also play an important part in producing the initial dilatation.

In this case air pressure cannot be considered, for the child had never breathed, nor were there any pleural adhesions, and the cause of the condition must be sought elsewhere.

In the developing lung the bronchioles terminate in a bulbous extremity into which groups of atria open. Groups of air cells or alveoli which form the air sacs open into these atria. The alveoli are not formed until about the sixth month of intruterine life, and before respiration commences they are lined with cubical epithelium which gradually becomes flattened when respiration occurs.

In our specimen the microscopical state of the tissues indicates that the cysts have not been recently formed, and their origin from the alveoli cannot be admitted in view of the late development of the alveoli. They must therefore be due to dilatation of the atria, infundibula, or bronchioles.

The absence of columnar or cubical epithelium in even the smallest cysts and of any trace of muscular or elastic tissue in their walls tends to exclude an origin from bronchi or bronchioles. Such a condition is, however, found in ordinary bronchiectasis, where the pressure of the retained secretion causes flattening of the cubical or cylindrical epithelium, while the stretching causes atrophy and disappearance of the muscular fibres. It would be difficult, therefore, to be certain from the histological disposition of the tissues whether we are dealing with a dilated bronchus or a dilated infundibulum, but the appearance of the smaller cysts particularly does not resemble bronchial dilatation. The cysts are found immediately under the pleura; and as the terminations of the bronchioles do not abut on the pleural surface this tends to exclude an infundibular origin. The condition is therefore a congenital cystic degeneration of both lungs caused by the dilatation of the atria.

The presence of mucoid or colloid matter in many of the cysts indicates that secretion from their walls is fairly active, and if, as is suggested by the microscopical sections, there was some inflammation of the bronchioles which caused blocking of their lumen, this would account for the retention of the secretion and dilatation from the consequent pressure.

## PNEUMOCOCCAL WOUND INFECTION:

NOTES ON TWO CASES.

BY

BERTRAM MUIR, M.B., B.S., F.R.C.S.,

HONORARY SURGEON, SHANTUNG ROAD HOSPITAL, SHANGHAI.

CASES of suppuration due to the pneumococcus in regions other than the upper and lower respiratory tracts and adjacent sinuses, the pericardium and peritoneum, the meninges, and the middle ear, are sufficiently rare to merit publication, especially when the infection is apparently primary and not blood-borne. Even the subcutaneous injection of a virulent pneumococcal culture in guinea-pigs causes death by septicaemia, with comparatively little local reaction, although a local abscess, with a characteristic fibrinous exudate, sometimes forms. The two cases here described were both "traversing" bullet wounds, and in both the primary infection appeared to be pneumococcal.

## CASE I.—Pneumococcal Infection of Diffuse Traumatic Aneurysm of the Axilla.

A Chinese soldier, aged 35, was shot through the right sub-clavicular region in November, 1924. The bullet entered anteriorly and traversed the pectoralis major, injured the third part of the axillary artery, and passed out through the teres major muscle. A tense pulsating swelling immediately formed in the right axilla, and he lost the use of the right hand. Turbance was noticed, and very little either wound. After a few weeks, the swelling became very painful, and the arm was abducted.

Six weeks later the swelling became very painful, and the

FIG. Left Lung.

overlying skin brawny-red and hot, and for the first time he felt ill and presented himself for treatment. When admitted the temperature was  $103^{\circ}$  and the right radial pulse was practically absent; from the clinical signs of the axillary swelling a diagnosis of diffuse aneurysm of the axillary artery was made. As it was obviously infected and seemed liable to rupture at any moment, surgical treatment was urgent.

#### Operation.

On January 18th I ligatured the third part of the right subclavian as a preliminary step, and then explored the axillary swelling. A longitudinal incision was made along the course of the artery, the pectoral tendons were incised, and a thick fibrous sac revealed, formed by the incorporated axillary fascia and costo-chondroid membrane anteriorly. This was incised, and yellow purulent fibrinous clot turned out. Brisk haemorrhage occurred from a hole in the third part of the artery, on the inner and lower aspect, which appeared to be the result of the original injury. The axillary vein and nerves were matted together in the outer wall of the sac, but eventually I succeeded in ligaturing the vessel above and below the openings, and the haemorrhage ceased. The remaining purulent clot was turned out, the pectoral tendons sutured, and drainage tubes inserted. A culture of the pus showed a pure pneumococcal growth.

Two days later it became evident that infection had spread along the course of the brachial artery to the antecubital fossa and along the ulnar nerve to the olecranon process. The abscesses were incised at these points and drained; culture again yielded pneumococci. The patient made a slow but uneventful convalescence.

#### CASE II.—Pneumococcal Infection of Left Supraclavicular Region.

A Chinaman received a revolver bullet in the left supraclavicular region on February 21st and was admitted to hospital three days later. A small round wound through the clavicular head of the left sterno-mastoid, just above the clavicle, was discharging pus. A skiagram showed the bullet to be lodged in front of the neck of the first rib.

#### Operation.

On February 28th I turned back an angular supraclavicular flap and explored the left subclavian triangle. The bullet was found lying on the neck of the first rib, between the fibres of the scalenus medius and longus colli muscles, beneath the lower fibres of the brachial plexus. The pleural dome and lung apex were uninjured. The bullet was removed without difficulty and drainage established. Three days later the temperature rose to  $103^{\circ}$ , and a reddened fluctuating swelling was observed in the delto-pectoral region. On incision this was found to extend deeply to the axillary sheath, and a quantity of yellow fibrinous pus was evacuated, which on culture yielded pneumococci. The patient made an uneventful convalescence.

These cases are only of scientific interest from the infection standpoint, as pneumococcal infection of wounds is very rare; indeed, I can find no recorded cases in a fairly extensive perusal of current medical literature. Both lesions were in the vicinity of the thorax, but even in Case II there was no lesion of the lung or pleura. Possibly the infection was from the patient's clothing, which in each case had been traversed by the bullet and was filthy. Another interesting fact was that infection spread along the vascular sheath in each case, without any marked local reaction after operation. In each case drainage and enol irrigation proved a satisfactory method of treatment for the secondary abscesses.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### PERFORATION OF THE JEJUNUM DURING AN ATTACK OF LOBAR PNEUMONIA:

##### LAPAROTOMY: RECOVERY.

PERFORATION of the jejunum (apart from injury) is an exceedingly rare condition; I can find no record of a case similar to that about to be described.

Mr. B. B., aged 24, had a "chronic appendix" removed through a gridiron incision in April, 1923. He made a rapid convalescence, and remained in perfect health until November, 1924, when he was seized with acute pains in the chest. The condition was diagnosed and treated as lobar pneumonia. The right lung was consolidated, and his temperature, after remaining consistently high for six days, gradually crept down towards normal. On the seventh day after the onset of his illness he had severe abdominal pains, the abdomen became distended, and vomiting was a troublesome feature. He had intractable diarrhoea, although previously he was constipated. I examined the patient three days after the beginning of the abdominal symptoms. He was acutely ill, semi-pulse 120, respirations 52. There were signs of consolidation of the right lower lobe of his lung. The abdomen was ballooned, immobile, rigid, tender, and tympanitic. The area of liver dullness

was not appreciably diminished, and shifting dullness could be detected in the flanks. As the abdominal muscles were on guard, no mass or viscous could be palpated. Apart from some tenderness of the pelvic peritoneum no other abnormality could be detected on rectal examination.

#### Operation.

Although the patient seemed moribund immediate coeliotomy was decided upon. He was anaesthetized with gas and ether, and 6 c.cm. of stovaine (light solution) was injected into the lumbar spinal theca. The abdomen was explored through a right paramedian incision which displaced the rectus muscle outwards. On opening the peritoneal cavity a large quantity of gas and dark-brown fluid escaped through the wound. As the abdominal contents were bathed in fluid, and the intestines grossly distended and glued together in places, the exploration was conducted under the greatest difficulties. The stomach, duodenum, and gall bladder were normal, but about 12 inches from the duodeno-jejunal flexure a circular perforation, a quarter of an inch in diameter and surrounded by a narrow strip of yellow necrotic tissue, was found on the ante-mesenteric border of the distended jejunum. There was no evidence of any induration or scarring around the perforated zone which would be suggestive of a previous chronic ulcerated condition of the gut. The breach in the jejunum was invaginated by two purse-string sutures of fine catgut and a protective omental pad applied to the site. About 6 inches further down the gut there was a circular gangrenous patch which was similarly invaginated and guarded with an omental pad. After this procedure no further examinations of the intestine were possible owing to the patient's critical condition; and, after providing for drainage of the pelvis and right iliac fossa, the abdominal wound was closed in three layers.

The patient rallied splendidly after the operation. He was able to return home and resume light work five weeks after the exploration. When seen some three months after the operation he reported himself as being quite fit and sound.

It is to be presumed that the gangrenous patch in the jejunum and the perforation were due to septic infarcts; yet it is interesting to note that there was no evidence of infarction elsewhere.

RODNEY MANGOT, F.R.C.S.,  
Surgeon, Royal Waterloo Hospital, London.

### FRACTURE OF BOTH PATELLAE BY MUSCULAR ACTION.

THE following case is thought worthy of record. The patient was under the care of Dr. R. S. Dickson of Palmer's Green, at whose request I operated, and to whom I am indebted for the following notes.

R. C., male, aged 20, was admitted to the Passmore Edwards Hospital, Wood Green, on September 8th, 1923, with the history that while playing tennis on that date "he had jumped upwards, suddenly between 2 and 3 feet to take a high ball at the net," when something snapped in both knees and he fell to the ground.

Skiagram, L. knee.

Skiagram, R. knee.

On examination he was found to have fractured both patellae transversely. On the left side there was considerable separation of the fragments. On the right side the lower fragment was small, and there was less separation. On September 18th both knees were subjected to operation and the fragments secured in apposition with silver wire.

Convalescence was uneventful, and he resumed business on November 15th, 1923.

That both patellae should give way, as in this case, must be unusual. We were unable to find any evidence of abnormality in the osseous system. The patient was an exceedingly athletic and well developed young man, with a sound family and medical history. Moreover, the bones at operation were quite normal in texture.

London, W.

T. TWISTINGTON HIGGINS, F.R.C.S.

## British Medical Association.

## CLINICAL AND SCIENTIFIC PROCEEDINGS.

## KENSINGTON DIVISION.

## MEDICAL APHORISMS.

At a meeting of the Kensington Division held on April 23rd, with Dr. WALTER E. FRY in the chair, an address was given by Dr. SEYMOUR TAYLOR, consulting physician to the West London Hospital, entitled "Some medical aphorisms."

*The Abdomen.*

(1) A tuberculous abdominal cavity in a child is best left alone so far as surgery is concerned. Nature often effects a cure under the influence of good food and sunshine. Most of you will agree with this; but it is only seniors like myself who have actual experience of such patients surviving, not only to maturity, but even to the verge of old age (60 to 65).

(2) The abdominal cavity is more susceptible to shock than is any other part of the body. Therefore in all abdominal operations there should be as little handling and exposure of the viscera and intestines as possible. This, again, will meet with recognized approval by all. But I do find, in this age of anaesthesia, when quickness of manipulation is not so valuable a factor as it was in former days, that some younger surgeons appear to dally somewhat when performing a laparotomy. Short of want of due care and precautions, the operation should be completed as quickly as possible. A distinguished soldier noticed that many of his men were put out of action by fragments of shell which had struck, but not perforated, the abdominal walls, whilst other men advanced to the attack for considerable distances, although they had sustained perforating bullet wounds of the thorax. The explanation which I afforded him was on the above lines.

(3) Bladder syncope is not so freely known or recognized as it should be. I have notes of seven patients, all males, who have suddenly fainted at the termination of the act of micturition on rising. The explanation which I advance for this alarming event is that the venous tension in the inferior vena and abdominal veins in general is suddenly relaxed by removal of the pressure of a hollow, but fluid-containing, viscus.

(4) In prostatic enlargement there is always a large amount of residual urine left over even after the bladder catheter has been passed. This residual urine decomposes, and may become the starting point of bacilluria. In many cases this residual urine may to a large extent be evacuated by making the patient micturate when lying in a prone position on a couch in which a utensil is fitted under an aperture on the under surface. If the legs and buttocks are raised above the level the relief is still more complete.

(5) An appendix abscess which has escaped diagnosis may rupture into any neighbouring cavity or hollow viscus, or by numerous sinuses in the loin or the front abdominal wall. I have recently seen a case in which laparotomy was about to be performed, and in which the abscess tumour suddenly disappeared, having discharged itself into the ascending colon. Microscopical examination of the faeces proved this diagnosis to be correct. Therefore the existence of a sinus in the abdominal wall should always suggest the possibility of its being connected with an appendix abscess.

(6) In nearly all cases of diseases of the anus and rectum there is marked anxiety and distress, compelling the patient to pay large fees in order to obtain the best surgical advice. I have not noticed this mental distress so well marked in any other form of disease.

(7) It is well known that in malignant disease, whether of the abdominal cavity or of any organ, the downward curve of the patient's vitality is steady, regular, and uninterrupted. But it is not sufficiently recognized that the final stage comes very often with startling suddenness. The patient is, or was, to all appearances no worse to-day than he (or she) was a week ago, when we are surprised next morning to have a message that death had occurred during the night. I have not infrequently noted this.

*Heart and Circulatory System.*

(1) As a rule, all diastolic murmurs are more serious than systolic murmurs. This is, I believe, accepted by most clinicians. Aortic regurgitation is a dangerous condition by itself, and, as is well known, it may terminate suddenly without any apparent increase of symptoms. But, in my experience, now obtained from noting many cases, the patient is more comfortable, and even able to perform fairly arduous muscular exertion, if in addition to the aortic insufficiency he has also mitral regurgitation, thus affording a safety-valve overflow from a labouring left ventricle. The tricuspid safety-valve action on

the right side of the heart is one of the first lessons we learn in our physiological textbooks.

(2) In aneurysm of the aorta it is the saccular form which ruptures and destroys life. The fusiform aneurysm is more responsible for death by prolonged pressure on nerves, veins, and other neighbouring structures. I formed this opinion after many years' experience in the *post-mortem* room.

(3) Given a valvular lesion of the heart, it is better that the murmur should be a loud one, as it is well to bear in mind that the patient dies not so much from a roughened or incompetent valve as from failure of the muscular driving power of the auricle or the ventricle. A loud murmur, therefore, is indicative that the heart muscle is still vigorous, and is not in itself a cause for undue alarm.

*Drugs.*

(1) As a rule the indications for the administration of opium outweigh those against it. I have known patients who have swallowed fairly large doses of laudanum with good effects, even when it was deemed unwise to allow a small dose.

(2) Small doses of morphine will cure whooping-cough in children much more speedily than any other remedy. It is only a matter of dosage, even when treating infants. Osler is reported to have said that if he had any drug to prescribe for a child with whooping-cough he should select paregoric.

*General.*

(1) The skin and muscles in chronic alcoholics, especially women, are hypersensitive to cold and pressure. A cold hand or the pressure of a stethoscope is immediately resented, and thus often confirms one's diagnosis. We should bear in mind that peripheral neuritis is fairly common in alcoholic women.

(2) I have never satisfied myself that I have ever seen a case of vicarious menstruation. I doubt if such a phenomenon ever occurs.

(3) *Arcus senilis* is by no means an indication of premature old age. I have observed it in young men and women between 30 and 40 years of age who yet lived to be septuagenarians. A dripping nose, shedding a clear fluid, is in my experience a much surer sign of senility.

## Reports of Societies.

## FIBROCYSTIC DISEASE OF THE HUMERUS.

At a meeting of the Bristol Medico-Chirurgical Society held on May 13th, the President, Dr. J. O. SYMES, in the chair, Mr. A. W. ADAMS read a paper on a case of fibro-cystic disease of the humerus. Mr. Adams introduced the subject by slides showing the process of ossification at the epiphyseal line of long bones, a region particularly liable to disorders affecting growth as well as to infections. Diseases of the osseous skeleton were then classified by age periods, and also by etiological factors. Twenty-eight slides were shown to illustrate achondroplasia, rickets, multiple exostoses, septic infection of bone, syphilis, tuberculosis, osteitis deformans, multiple enchondromata, and primary and secondary neoplasms. Mr. Adams pointed out that quite good union might occur in a bone which had suffered a spontaneous fracture from neoplastic metastasis, and advised treatment of such fractures on the usual lines. In the diagnosis of primary neoplasm of bone neither skiagraphic nor pathological evidence was so satisfactory as clinical experience. An illustration of one case of osteogenesis imperfecta and a skiagram of another were shown. A case of osteitis deformans observed over a period of five years was shown in which the tibia only was affected; the softening and bending were noted, and also the tendency for arrest of the process after a time. Attention was called to the frequency of sarcoma in such bones as a late phenomenon. The literature of fibro-cystic disease of bones was reviewed; this disease often affected one bone only. The comparative frequency of the affection being localized in certain positions was observed, such positions being the upper end of the humerus, either end of the femur, and the upper end of the tibia. Mr. Adams described his case, first seen sixteen months previously; the disease had occurred in a boy at the upper end of the humerus; spontaneous resolution had occurred after three fractures. No treatment beyond splinting had been attempted. Mr. Adams thought such a course in this disease had not previously been described. He put forward the view that

the disease tended to occur at joints allowing of rotatory movement, and suggested that repeated rotatory stresses might be an element in its etiology. An endocrine factor had also been suggested.

Dr. T. C. BRETNALL doubted whether rotatory strains were greater at ball and socket than at hinge joints. He thought that such joints as the shoulder, where rotation was a normal movement, suffered less trauma from rotatory stresses than hinge joints.

Mr. A. R. SHORT mentioned another case of fibrocystic disease in which both the tibia and the femur were affected.

Mr. C. A. MOORE referred to a case under his own care in which pathological reports from different sources on the same piece of tissue had varied considerably. He agreed that spontaneous fractures due to neoplastic metastasis might be successfully treated on ordinary lines, and mentioned a case of simultaneous fracture of both femora treated in this way.

### VITAMIN VALUE OF MILK.

At a meeting of the Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on April 24th, the President, Dr. C. M. WEST, in the chair, Professor H. PRINGLE reported the results of an investigation into the vitamin values of Dublin cow's milk and of human milk, and summarized the present position regarding the occurrence of vitamins in natural foodstuffs and their importance as shown by recent work on the subject.

Professor Pringle pointed out the clinical importance of the subject. Although typical deficiency diseases were of rare occurrence in a population on a mixed dietary, yet there was growing evidence that many atrophic conditions with malnutrition and deficient growth, especially in children, were due to lack of vitamins, particularly B. The evidences of B deficiency were lack of appetite, less absorption, increased nitrogen loss, and atrophy of lymph tissues. Lack of A gave rise to increased liability to infections, eye inflammations, rheumatism, and enteritis; lack of C gave rise to modified scurvy condition; lack of X (antirachitic) caused deficient ossification and rickets. It was quite possible for a mixed diet to be deficient in vitamins though ample in other respects. A diet made up of the following foodstuffs would be deficient unless enormous quantities were eaten: sugar, rice, jam, white bread, potatoes, lard, margarine, the coarser kinds of fish, cod, haddock, lean meat, bacon. Even if butter and cheese were added there would still be a very low value of B and C. The danger of deficiency had to be guarded against particularly during lactation and infancy; the amount of vitamins in the milk varied with the diet of the mother. The results of the investigation showed the vitamin value of Dublin cow's milk to be very low, a daily minimum of 10 c.e.m. being necessary to maintain growth in a rat on a vitamin-free diet; this compared with Cambridge milk 2 c.e.m., Liverpool 6 c.e.m., Norwegian 2 c.e.m., Sydney 10 c.e.m. The low vitamin value of Dublin milk was chiefly due to lack of B. The addition of butter to the diet of a rat on vitamin-free diet plus 10 c.e.m. of milk did not produce any improvement, but the addition of 0.5 gram of yeast a day had a marked effect at once, bringing about normal growth. The value of human milk, as tested on rats, was very low, a minimum of approximately 17 c.e.m. a day being necessary to maintain growth. The minimum figure for Jersey cow's milk from an animal on the grass and receiving grain in addition was 7 c.e.m.; this milk had a very high cream content. Professor Pringle then showed the growth curves obtained as a result of feeding rats on a vitamin-free diet plus (a) Dublin cow's milk obtained from a local dairy, (b) Jersey cow's milk, and (c) human milk.

### Determination of Cyanates in Blood.

Mr. E. G. MONTGOMERY, introduced by Dr. W. Fearon, then read a paper on the determination of cyanates in blood. He said that the occurrence of cyanic acid during the oxidative deamination of glycine, alanine, and sarcosine had been cited in support of the hypothesis that this acid was an important intermediate product in the forma-

tion of urea in the animal body. In his experiments fresh blood from the rabbit and the cat was examined for the presence of cyanate, and in each case a positive result was obtained. For the rabbit the cyanate value was found to be 0.7 mg. per 100 c.e.m., and for the cat 1 mg. per 1,000 c.e.m. expressed as free cyanic acid. The plasma obtained was divided into two equal portions, A and B. To B was added 0.2 gram ammonium sulphate, and both tubes were incubated for twenty-four hours; an equal volume of concentrated Turrel's reagent was then added to each, and the contents filtered. The filtrates were treated with equal volumes of glacial acetic acid and 1 c.e.m. of a 10 per cent. solution of xanthidrol in methyl alcohol. After twelve hours the precipitates of dioxanthyl urea were filtered off, washed, dried, and weighed, and the increase in the urea content of B gave the value of the cyanate present. A confirmatory test for cyanate was carried out on plasma after acidification by addition of decinormal sulphuric acid, which would destroy any cyanate present. No appreciable increase in urea was observed after incubation with the ammonium salt as before. By means of control experiments the limits of error were found to lie within 0.2 mg. per 100 c.e.m. The occurrence of cyanic acid in plasma suggested that it was either a precursor or a product of urea formed in the organism; the available evidence pointed strongly to the former view. Its presence would explain the varying values of blood ammonia obtained by different observers, and furthermore it might play an important part in the formation of the nitrogenous substances whose origin was still obscure.

## Reviews.

### THE ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH.

THE distinctive aim of the St. Andrews Institute for Clinical Research, founded by the late Sir James Mackenzie, has been the study of the common diseases of the people of this country. The circumstances in which the Institute was founded, the zeal and originality of its distinguished director, and the novel methods of study which he introduced, are well known, and the progress made has been watched with keen interest, particularly by members of the profession most familiar with the difficulties of the task—namely, the general practitioners. In the introduction to the first volume of the *Reports of the St. Andrews Institute for Clinical Research*,<sup>1</sup> published in 1922, Sir James Mackenzie described the principles on which the work of the Institute was based, and indicated the direction in which exploration was proceeding. The contents of this volume were a part of the outcome of the first year's work at the Institute, and included two notable papers, one by Sir James Mackenzie, entitled "An address on clinical research," and the other by Dr. Andrew Rowand, recording a census of the complaints from which the sick population of St. Andrews and the surrounding districts suffered, was published under the title "The present state of medical knowledge regarding the diseases common among the people." The systematic study of the symptoms of these diseases led to the enunciation of a law governing the production of a large number of symptoms which was described in an article in this JOURNAL (1921, i, p. 147). Two of the later articles in this volume were also published in this JOURNAL, that by Professor P. T. Herring, entitled "The sensations as reflex manifestations of disease (1921, ii, p. 469), and an article by Sir James Mackenzie on "Prognosis" (1921, i, 797). In the second volume recently published the first two articles are reprints from papers published by Sir James Mackenzie in this JOURNAL, the first on "The application of the principle of the reflex arc to the interpretation of cardiac signs," and the second on "Some general principles of cellular and organic activity in relation to symptoms." The new ideas which these articles express have been studied from the

Professor D. Winterston, and other members of the staff of the Institute who have contributed to this volume. We must mention also "A clinical study of influenza" written by Dr. J. H. P. Paton.

The regular publication of these reports is a convenience which many practitioners who are following the work of the Institute with interest will appreciate. They are valuable also because, taking them in sequence, the reader catches a glimpse of the wide outlook of this distinguished physician on the problem of human disease, and can notice how field upon field opened up before his penetrating eye.

### PLASTIC AND REPARATIVE SURGERY.

THE records of cases treated by Dr. CARL BECK and published in his book on *The Crippled Hand and Arm*<sup>2</sup> show that he is a surgeon of resource and ingenuity, possessed of the patience necessary for the cure of contractions and defects. The conditions considered are due to abnormal development, injuries, and disease, and in most of them the chief difficulties were caused by the presence of scars, which necessitated many plastic procedures described in this book.

After two chapters on the anatomy and physiology of the parts concerned, which should scarcely be necessary for the surgeon, congenital defects and deformities are dealt with. Except in the case of webbed fingers the outlook on this class of cases is not very cheerful, although what has been called by French writers "phalangization of the metacarpals" may possibly be of value in cases of defect of phalanges only. The account of the treatment of the hand crippled by injuries involves a great many plastic procedures, including ingenious methods of reforming distorted and replacing lost finger-nails.

Dr. Beck admits that a tendency to keloid of scars is common, and a great drawback to treatment, especially after burns, but he does not offer much advice as to how it is to be prevented. Tenoplasty and nerve suture receive some notice, and the author seems to have been fortunate in his experience of the results of the latter operation.

Throughout this book it is that side of surgery concerned with cutting operations which receives nearly all the consideration. No apparatus is described, and little if any mention made of massage, manipulation, and gradual methods, although no doubt it is intended to be understood that these play their parts as adjuncts. A few pages on artificial hands and arms call for no comment. A short chapter on technique ends the book.

Anyone who is about to undertake one of these long and difficult cases will be well advised to consult this book, because it consists so largely of records of actual cases and because Dr. Beck is not afraid to record his unsatisfactory as well as his triumphant results.

### SURGERY OF CHILDREN'S DISEASES.

A BOOK by Professor L. OMBRÉDANNE has appeared in the well known French collection entitled *Précis Clinique et Opératoire de Chirurgie Infantile*.<sup>3</sup> The volume before us is written in a simple and straightforward style; it is addressed both to students and graduates, and gives a clear account of French opinion on surgical branches of pediatrics. It is divided into two parts: the first and shorter is concerned with general pathology, and the second with diseases of different regions of the body. Operative treatment is discussed in detail, and a good deal of space is given to orthopaedic work. One feature of this useful book to which we wish to call attention is that, in discussing congenital malformations, the author departs from the customary anatomical scheme and relies on the much more suitable and instructive embryological classification.

The surgery of children's diseases is recognized to be a special branch of surgery, and this book is a very useful introduction to it.

### A PRECIPITATION TEST FOR SYPHILIS.

A NEW modification of the precipitation test for syphilis is described by Dr. R. L. KAHN in his book *Serum Diagnosis of Syphilis by Precipitation*.<sup>4</sup> The procedure for carrying it out is a simplification of the ordinary Sachs-Georgi test which has been reached after a long period of study. In the earlier chapters of the book Dr. Kahn describes the experimental work which led him step by step to the perfection of what is now spoken of as the Kahn precipitation test.

The details of this experimental work are interesting from the theoretical point of view, but we must pass these by in order to give a short account of the distinctive features of Dr. Kahn's modification of the precipitin test. The ingredients of his test are serum, free from all visible particles, and antigen composed from an alcoholic extract of an ox's heart. The preparation of this antigen requires the extraction of definite amounts of powdered ox's heart in measured amounts of ether, after which the powder is extracted in alcohol and cholesterol added. The first step in the test is the titration of antigen to determine the minimum amount of salt solution which, when mixed with antigen, will produce a precipitate capable of readily dissolving on further addition of salt solution. In carrying out the routine test 1 c.cm. of antigen is added to a standard dilution tube and the amount of salt solution indicated by previous titration is added to a similar tube. This salt solution is poured into the antigen as rapidly as possible and thoroughly mixed, after which it is allowed to stand for ten minutes. Graded quantities of this diluted antigen are measured into three tubes, to each of which 0.15 c.cm. of clear inactivated serum is added. The serum and antigen must be well mixed and shaken vigorously for two minutes. Then 0.5 c.cm. of salt solution is added to each tube. The addition of the salt solution clears the negatives and disperses the precipitates in the positives, rendering the reading of results easier. After addition of salt solution to each the tubes are shaken for several seconds to permit thorough mixing and allowed to stand five minutes at room temperature before making the final reading of the results. Dr. Kahn says that fifteen minutes' incubation in the water-bath at 37° C. produces sufficient clumping of the precipitates to make the reading of the results easier, particularly in the case of weak reactions. Of course, antigen controls, serum controls, and positive and negative controls must be carried out at the same time.

These are the distinctive features of Dr. Kahn's technique. From the figures reported in this book it would seem that this modification agrees well with the orthodox Wassermann reaction, but judgement on such a proposition as this can only be given by further experimental work. The test sounds so simple that it certainly deserves a trial.

### MELLOR'S "CHEMISTRY."

WE are now in possession of Volume V of Mellor's *Chemistry*.<sup>5</sup> It deals with boron, aluminium, gallium, indium, thallium, scandium, the rare earths, and carbon (part 1). Notices of the preceding volumes which have appeared in this JOURNAL have expressed approbation of the completeness of the author's treatment, the clearness of his expression, and the comprehensive and connected form of his presentation. Those qualities are well maintained in the volume before us. There is not a great deal in the way of new discovery to be recorded in the chemistry of the elements dealt with, but the more modern methods of physical chemistry are used to enlarge the explanation of their chemical behaviour. Both these and the subject of their application have acquired enhanced clearness in the author's hands; instances of their association chosen for reciprocal illustration are well selected. An example of this appears in a discussion of the acid properties of boric acid where a diagram is given showing a comparison of the curve of the electrometric titration of boric acid, with, and without, mannitol, by the side of the

<sup>2</sup> *The Crippled Hand and Arm*. By Carl Beck, M.D. London: J. B. Lippincott Company. 1925. (Med. 8vo, pp. xi + 233; 362 figures, 30s. net.)  
<sup>3</sup> *Précis Clinique et Opératoire de Chirurgie Infantile*. Par L. Ombredanne. Paris: Masson et Cie. 1923. (Cr. 8vo, pp. xvi + 1133; 581 figures. Paper cover, 1r. 40; bound, fr. 45.)

<sup>4</sup> *Serum Diagnosis of Syphilis by Precipitation*. By R. L. Kahn, M.S., D.Sc. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1923. (Demy 8vo, pp. xii + 237; 5 plates, 15s. net.)  
<sup>5</sup> *A Comprehensive Treatise on Inorganic and Theoretical Chemistry*. Vol. V. By J. W. Mellor, D.Sc. London and New York: Longmans, Green and Co. 1923. (Roy. 8vo, pp. x + 1004; illustrated, 65s. net.)

corresponding curve for hydrochloric acid. On the same page is given a list of many indicators with the hydrogen ion concentrations shown by their respective changes of colour.

The article on boron contains a section of interest dealing with perborates, which are comparatively new articles of commerce. Sodium perborate is important as a compound containing a surplus of oxygen which it liberates in the same way as hydrogen peroxide under the action of the same chemical agents. The historical parts of the author's work are always entertaining. It appears that during a certain period of the Middle Ages the manufacture of alum was a jealously guarded monopoly of the Pope, to whom it was a rich source of revenue, alum being an important requisite of dyers. The claim in favour of cerium, a term proposed for the element discovered by Coster and Hevesy and named by them hafnium, is discussed. With a ready grasp of the evidence and with judicial fairness the author exposes the weakness of this claim.

The history of carbon monoxide as here related furnishes the speculative student with an excellent lesson in analytical logic and the constructive use of evidence. Priestley held it to be phlogisticated water, adducing in favour of his argument the fact that inflammable air is produced when steam is passed over red-hot charcoal. The opponents of the phlogiston theory were perplexed by the fact that they were confronted with a compound of carbon and oxygen which had not the incombustible property of the already known oxide of carbon, which later became distinguished as the dioxide. Even after Cruickshank had shown that it contained nothing but carbon and oxygen, Berthollet held to the objection that if it were true that it contained more carbon than there was in carbon dioxide it ought to be specifically heavier. Carbon monoxide has certain properties which may be called hypnotic. On this fact is founded an interesting discussion on the mode of action of chloral hydrate. It is known that chloral hydrate may disengage carbon monoxide under oxidizing agencies such as those existing in the circulation, and it is suggested that the effect of such disengagement affords a more acceptable explanation of its hypnotic action than the view that it is decomposed with generation of chloroform. This is an instance of the many items of curious interest which are scattered through the pages of the book in their proper context with regard to chemical phenomena, but are yet remote from where they would be expressly sought. For this reason we suggest that the finished work should be supplemented with a general index containing sufficient references to enable all such matters to be easily found.

### NAUTICAL COMPARATIVE ANATOMY.

SIR ALAN MOORE'S delightful book *Last Days of Mast and Sail*\* bears only two reminders that its author is a medical man. But for the confession in the preface a reader unfamiliar with the author's name would certainly guess him to be a professional sailor, and fail to notice the clue to his calling betrayed by the alternative title "An Essay in Nautical Comparative Anatomy." This is an intriguing book. It roams from square sails to lateen sails, spirit sails, gaff sails, and every type of rig. Sir Alan Moore says that as long as he can remember he has been fascinated by ships and boats, which throw on him a spell "like that which is cast on many by birds." Four years in the R.N.V.R. as midshipman and sublieutenant gave him a greater insight into naval ways, and during the war he served as a temporary surgeon in the navy. All his life, it seems, he has taken every opportunity to learn the ways of seafaring people, to study their craft, and to familiarize himself with every detail in the handling of a ship.

His motive for writing this unusual book had best be given in his own words: "The use of sails is so rapidly passing away that it behoves us, the last of the ancients, the last generation perhaps, to know and to use the sail, the oar, the beast-drawn cart, and wind-driven mill, to

record what we saw of a dying age, lest in the blaze of the new era which blinds the majority to the interest, nay the existence of so many beautiful and ingenious contrivances of immemorial use, they be utterly forgotten, and lest when, sated with inventions or because they have ceased to invent, men turn again to a time recent but remote, they find no record of vanished but familiar things that furnished much of the setting of their grandfathers' lives."

No one would dispute the likelihood of Sir Alan Moore's prophecy, for certainly the sailing ship is passing away, to be replaced by steam- and petrol-driven boats. But the beautiful ships and ingenious contrivances of seafaring life in bygone days will not vanish without record, for in this charmingly written and elegantly illustrated book an accurate record has been preserved. Its pages will be fingered affectionately by sailors who understand every familiar nautical phrase, and it will be a textbook of romance to all children who feel the irresistible call of the sea.

### NOTES ON BOOKS.

PROFESSOR ALEXANDER FINDLAY'S *Physical Chemistry for Students of Medicine*<sup>1</sup> is a pioneer piece of work. As the study of medicine rests on physiology, so is physiology raised on foundations furnished by physics, chemistry, and other academic divisions of learning. Chemistry in its modern development has become more and more identified with the physics of the molecule. For physiology this fact is of momentous consequence, since the functions of organic life are regulated by dynamic properties. Professor Findlay's treatment of the subject is suitable for any student of physical chemistry, but it is particularly adapted for students of medicine in that the facts dealt with are referred to their physiological bearings. How directly significant these facts are may be illustrated by the following passage: "In febrile conditions reduced viscosity is usually found owing to the rise of temperature, and since the temperature coefficient of viscosity of blood is high (in some cases as high as 3 per cent. per degree centigrade), the reduction in viscosity may be considerable, and the strain placed on the heart will be correspondingly reduced." The book is characterized by aptly chosen references to matters of medical interest touching on bacteriology, enzymes, antitoxins, and other subjects. It should have a foremost place in every student's scheme of work; its contents are the bed-rock of what he is to learn in the future.

The work on *Infection, Immunity, and Inflammation*,<sup>2</sup> by Dr. FRASER B. GURD, lecturer in applied immunology and in surgery at McGill University, Montreal, is, as its subtitle states, "a study of the phenomena of hypersensitiveness and tolerance, and their relations to the clinical study, prophylaxis, and treatment of diseases." After an introductory chapter dealing with the defensive and offensive reaction of the body against irritation, the author discusses the nature of infection and infective agents, immunity and immunization, and the reactions of animals and man. Special chapters deal with the application of immunity principles to the prevention and treatment of diseases, such as diphtheria, tetanus, pneumonia, dysentery, and hay fever. The laboratory worker and the clinician will find the volume a useful handbook.

The *Catalogue of Pathological Preparations in the Museum of the Royal Samaritan Hospital, Glasgow*,<sup>3</sup> has been arranged for publication by D. MCINTYRE and JOANNA T. RAE on the basis of a catalogue compiled by Dr. Mary Hannay. The 286 specimens in the museum are arranged in twenty-three series, classified on a basis that is partly anatomical, partly pathological. The various diseases of the female generative organs appear to be well represented; brief descriptions of the specimens are given and notes of the cases when available. Much care has evidently been bestowed on the microscopical preparations; a list of slides of special interest or of instructional value, available for the use of students, is given. A useful addition, which we do not remember to have seen in other museum catalogues, are the cross-references appended to each section. The authors are to be congratulated on the way in which they have accomplished their task.

SATURDAY, MAY 30TH, 1925.

## ARTIFICIAL PRODUCTION OF THE ANTIRACHITIC VITAMIN.

THE discovery that irradiation with ultra-violet light causes the antirachitic factor to appear in substances which previously were inert represents a very important advance in medical science. In the first place, this discovery solves the mystery of rickets being cured by two such divergent specifics as sunlight and cod-liver oil; secondly, it promises to throw much light on the origin and nature of vitamins; and thirdly, it renders possible the artificial production of at least one vitamin.

As long ago as 1919 Huldseinsky proved that ultra-violet light could cure rickets, but for some years attention was diverted from this fact by another discovery—namely, that substances rich in fat-soluble vitamins acted as specifics in rickets. At first the antirachitic vitamin was believed to be identical with the growth-promoting vitamin A, but it is now believed that these two factors are distinct, although they are both fat-soluble and are usually associated. The prolonged controversy concerning the relative influence of bad housing conditions and faulty diet in the production of rickets was finally set at rest in a general agreement that rickets could be cured either by exposure to ultra-violet light or by administration of the antirachitic factor. The connexion between these two specifics was, however, at first a complete mystery; but the problem has now been solved by work which has been conducted almost simultaneously in several laboratories both in this country and in the United States of America.

Steenbock<sup>1</sup> and Hess<sup>2</sup> both showed in 1924 that rats fed on a rachitic diet were benefited if their diet was exposed to ultra-violet light, and this explained previous work, which had suggested that rachitic rats gained, not only by direct exposure to ultra-violet light, but also if their environment alone was irradiated. Steenbock has since shown that a large number of foodstuffs, but not all, can be activated by exposure to ultra-violet light. Drummond and other workers<sup>3</sup> in this country had meanwhile brought forward evidence indicating that the active antirachitic substance in cod-liver oil was closely associated with cholesterol. Steenbock, Drummond, and Hess have all since shown that solutions of chemically pure cholesterol, which have no antirachitic action, acquire this property after exposure to ultra-violet light. The antirachitic factor can therefore be produced from a pure chemical substance by the action of ultra-violet light. This effect is remarkable and unexpected, for Zilva in 1920 had shown that prolonged exposure to ultra-violet light actually destroyed the vitamins in cod-liver oil. The nature of the change produced by the ultra-violet light is unknown, but it would appear that it is of a chemical nature, that only a minute fraction of the cholesterol acted upon is activated, and that this fraction is destroyed by prolonged exposure. It is

certain that other substances besides cholesterol can be activated, and these substances are probably sterols related to cholesterol.

This discovery should have immediate and important practical results, since it makes it possible to confer antirachitic properties on a large number of foodstuffs. In particular it appears to be possible to render vegetable oils antirachitic. Further, it is to be noted that experiments<sup>4</sup> have already shown that rickets can be treated successfully with irradiated milk. The antirachitic factor is relatively stable, and it seems probable that means will be discovered for producing the factor in a concentrated form. The discovery should therefore render the prevention of rickets a comparatively cheap and simple matter.

Steenbock suggests that the antirachitic factor may also prove beneficial in other diseases where the calcium metabolism is deranged, and in diseases such as infantile tuberculosis, where sunlight and ultra-violet light have already been proved to have beneficial effects. The discovery that the antirachitic factor can be produced from the sterols gives us reasonable grounds for hoping that before long its chemical nature will be elucidated, and that means of isolation and concentration will be found. The other fat-soluble vitamins which promote growth and reproduction appear not to be produced by irradiation; but the discovery of a means for the production of one vitamin naturally encourages the hope that before long similar discoveries will be made in the case of the other vitamins.

## SUBURBANIZATION.

URBANIZATION is an ugly word. Suburbanization is an uglier, and the manner in which the process is developing around London suggests that the thing itself may be as objectionable as the term. Even within the last three or four years a dweller in an extending suburb finds that tree-shaded roads which afforded pleasant walks are being disfigured by great stretches of wooden hoardings plastered over with staring advertisements, and that the hoardings are in their turn displaced by long rows of shops and dwelling-houses which effectually conceal the country itself from the wayfarer. Greater London must be allowed to grow: that is for the present inevitable, whether we desire it or not. Queen Elizabeth thought the town was quite large enough in her time, but she little knew what was to follow. The growth, however, ought to be controlled, not only to ensure that the new houses may be judiciously and hygienically distributed, but also in such manner as to save whatever may be saved of the beauty of the country when invaded by the town. During the first two-thirds of the nineteenth century the extension of London was rapid to the south, but very slow in the north. Forty years or so ago there were few houses beyond Hampstead Heath; Hendon, for instance, was a village with a pond, which still remains. Edgware also was a village, and even Cricklewood was only a handful of houses. Now all that is changed, and penetration northward proceeds apace. The Town Planning Act provides the means of regulation and control. Hitherto, so far as we have observed, the power to form advisory committees for regional schemes of planning has been used mainly or wholly in industrial areas. The outstanding case is that of Manchester and the places of which it is the centre. Over seventy authorities have combined in this part of Lancashire to constitute a committee to consider the lines which should be followed in the

further development of that already thickly populated region. Other places where similar action is being taken include North and South Tyneside, Tees-side, Rotherham, Doncaster, Deeside and the Wirral Peninsula. Nearer London, and less notably industrial, are North-east Surrey, West Middlesex, and the Thames Valley. The powers of such committees are advisory only, not executive, but on that very account local authorities need have less hesitation in appointing them; their work is, in fact, of the greatest value.

It is well, then, that the county authorities of Hertfordshire should be taking counsel together as to how to direct the distribution of new dwelling-houses in their pleasant land. At a meeting in London the other day they were addressed by Mr. Neville Chamberlain, the Minister of Health, who urged the adoption of a regional scheme of town planning. He pointed out that the proposals would not involve expenditure, but would, on the contrary, save the outlay in which many big cities had become involved in order to undo the mistakes of the past. There is risk of a new kind of mistake being committed on a huge scale, for, as he truly said, the development of motor traffic has rapidly altered the whole problem, and unless proper lines are preserved the authorities may have later on to buy out at enormous cost buildings at present being erected on new roads. In preparing a scheme, Mr. Chamberlain held, not merely the economic but the aesthetic had to be kept in view. Any scheme for Hertfordshire should cover the whole county, and should include extension of the garden cities already in existence. It might also be necessary to go outside the county boundaries, and the Town Planning Act places no limit on co-operation. The meeting, which was presided over by the chairman of the county council, adopted a motion, proposed by the Mayor of Hertford and seconded by the Mayor of St. Albans, for the appointment of a joint town planning committee. This particular proposal, therefore, has been launched under most favourable auspices, and it is to be desired that other of the home counties—Buckinghamshire, for instance—should follow the example of Hertfordshire. An arresting letter on the subject from Mr. Patrick Abercrombie, professor of civic design in the University of Liverpool, has been published (in the *Times*) since the meeting. His point is that the most important and difficult task of the joint committee will not be the provision and control or even the amenity of arterial roads, nor the spacing of industries, nor the preservation of open spaces; the vital problem is the regulation of normal residential development, as between two methods of growth—"the ribbon unrolled along the roadside, and the radiation emanating from a central nucleus." The former not only inflicts the maximum destruction of rural beauty and social life, but is the most extravagant in respect of sewers, water, light, and police. The garden cities illustrate the advantages of the other method, which is, indeed, unconsciously followed in the ordinary growth of existing towns. The principles enunciated by Professor Abercrombie should receive most careful consideration by all who are engaged in such work as that of the Hertfordshire joint committee.

But there are wider aspects. Would not a scheme of populations based on long arterial roads bordered mile after mile by villas and bungalows bordered by munity life? Even though some inexperienced individuals may think that they can be self-sufficing, and will never want to go to church or cinemas or lectures or concerts, or may not have children needing to be sent to a local day school, other people have these

desires and obligations, which need to be brought within their reach. Every village has its shopping centre, suitable for its own inhabitants, but on this crazy plan of house-edging "arterial" roads such centres would be few and far between. The similar should have prevented anyone possessed of an ordinary amount of common sense from falling into an error so egregious.

England is more alive to-day than ever before to the blunders committed in the uncontrolled growth of towns since the industrial revolution which owed its origin to Watt's invention of the steam engine and resulted in the substitution of mass production in factories in towns for the domestic and village industries of the eighteenth century. But this generation should be particularly careful that in remedying, so far as may be, the evil results of urban overcrowding, a new offence by so distributing the dwellings which will be erected throughout the country that they not only blot out from the view of travellers along the main roads the pleasant picturesque scenery which has always been so notable a feature of rural England, but substitute for villages, small or large, long straggling "ribbons" of population which would be alike impracticable for local government and destructive of communal life.

#### MISSING LINKS.

In the course of a lecture delivered at University College on May 22nd in aid of St. Christopher's Working Boys' Club (Guild of University College, London) Professor Elliot Smith sketched the history of the various claims made in the past for the discovery of links that were missing in the chain of man's connexion with the apes, and discussed the significance of the Taungs skull recently recovered by Professor Dart in Bechuanaland. Professor Elliot Smith observed that, as Professor Bolk has emphasized, profound changes occur in the structure of the anthropoid apes in their development from birth to maturity; and the newborn gorilla and chimpanzee exhibit many traits, not found in the adult, that closely resemble those of the human baby. Professor Dart was handicapped in not having access to collections of anthropoid skulls such as are available in London. Hence he fell into the not unnatural error of claiming certain of these infantile characters in his fossilized baby ape that are shared equally by four-year-old gorillas and chimpanzees as evidence of a nearer kinship to man. The peculiarities of posture and poise of the head, and several of the features of the jaw and face, upon which he relied in substantiation of these claims, are expressions, not of human affinities, but of characteristically simian infaney. The size of the brain and the sum of the characters of the skull and face reveal the fact that *Australopithecus* is most nearly akin to the known African anthropoids, the gorilla and chimpanzee. But it differs profoundly from both of these apes in several respects, and certainly belongs to a hitherto unknown genus. In the absence of salient eyebrow ridges it resembles the orang, from which, however, it differs in most other respects. The shape of the cranium is so much longer and narrower (that is, more man-like) than those of the other apes that the question arises whether there has not been a *post-mortem* distortion to explain the length and the peculiar lateral flattening. But the evidence at present available—especially the lack of any exceptional asymmetry in the face and the fact that the jaws are definitely less prominent than those of young gorillas and chimpanzees—suggests that no such distortion has occurred, or, at any rate, nothing in any way adequate to explain the profound contrast between the Taungs ape and all the

other known anthropoids. These cranial characters, as well as the form and proportions of the nasal bones, the jaws, and teeth, afford definite evidence of a closer affinity to man than any living ape reveals. None of them individually is sufficiently great to raise the Taungs ape above the level of the gorilla; but collectively they do constitute impressive evidence in substantiation of the close kinship of *Australopithecus* to man's ancestors, and even the possibility that an ape of this genus may have been in the direct line of human descent. If, as has been claimed, the geological conditions in Bechuanaland were essentially the same when the Taungs skull was deposited in the limestone cave where it was found as they are now, the problem arises, How did this anthropoid ape wander thousands of miles from the present habitat of its relatives? Had it already, like primitive men, emancipated itself from the necessity of forest life? Or, alternatively, had it become specialized, like the baboons, to live under such conditions as prevail on the edge of the Kalahari desert? The answers to these questions have a direct bearing upon the claims that *Australopithecus* had already attained, not only the first stage in the process of refinement of its features, but also in its adaptability to more complex conditions of life, such as primitive man displayed when he freed himself from an arboreal or semi-arboreal existence. In attempting to arrive at a just appreciation of Professor Dart's achievement it has been necessary to call attention to the fact that some of the criteria upon which he based his inferences are evidence of infancy rather than of close human kinship. But this (Professor Elliot Smith concluded) should not blind us to the considerations (a) that he has rescued the only face and endocranial cast of a fossil anthropoid so far recovered, and (b) that it represents a hitherto unknown genus with interesting suggestions of affinity to man's Miocene ancestors.

#### YEASTS.

Dr. CHASTON CHAPMAN's presidential address to the Royal Microscopical Society contained some interesting references to the classification, structure, and physiological behaviour of yeast cells. It is customary to include within the group of yeasts all the unicellular fungi which reproduce by budding, but more strictly the term would be limited to such budding cells as are capable of forming ascospores, and the remainder, which do not form spores, relegated to the group of torulae. Present systems of classification of the yeasts are based on that suggested by Hansen in 1904, but Dr. Chapman follows certain recent French systematists and distinguishes five main groups. The first group, the schizosaccharomycetes, reproduces by transverse division. Hansen excluded them from his original system, but it is convenient to include them though their method of reproduction has a close affinity to that of bacteria. The second group, the zygosaccharomycetes, consists of yeasts in which some sexual conjugation precedes or accompanies the formation or germination of the ascus. This interesting group tempts speculation as to whether the great experiment of sex conferred benefit or otherwise on the yeasts. The third group, the true saccharomycetes, includes all those yeasts which reproduce mainly by budding and in which the formation of the ascus is not, so far as is known, preceded by any form of conjugation. Here belong the familiar yeasts of the bakery and brewery. The fourth group of non-alcohol producers includes the genera *Pichia* and *Willia*, yeasts which do not betray any trace of sexuality, and which usually develop in the form of a film on the surface of the liquids in which they are growing. The fifth group, including two or three genera, consists of yeast-like cells whose connexion with the saccharomycetes is somewhat doubtful. Dr. Chapman does not concur with the views of Wager and Peniston, who

look upon the main vacuole as the nucleus, and speak of the deeply staining structure (generally regarded as the nucleus) as the nucleolus. About the other structures visible within the yeast cell he has nothing fresh to say, but he gives a brief account of the different forms which fermentation takes according to the conditions under which the yeast cell is compelled to carry out its activities. Thus, whilst the ordinary *Saccharomyces cerevisiae* normally decomposes sugar with the production of alcohol and carbon dioxide and only about 3 per cent. of glycerin, when the fermentation is conducted in the presence of a considerable quantity of sodium sulphite the main products are acetaldehyde and glycerin in roughly equal molecular proportions, and instead of the normal 3 per cent. as much as 36 per cent. of glycerin can be produced. This was made use of by the Germans during the war in order to obtain glycerin for making munitions. The reading of this stimulating paper by Dr. Chaston Chapman calls to mind the closing sentence of that masterly treatise by Dr. Arthur Harden on *Alcoholic Fermentation*: "In every direction," he said, "fresh problems present themselves, and it cannot be doubted that as in the past the investigation of the action of the yeast cell will still prove to be of fundamental importance for our knowledge of the mode in which chemical change is brought about by living organisms."

#### PATHOLOGICAL RESEARCH AND ROUTINE EXAMINATIONS.

THE department of pathology and bacteriology in Leeds University has made gratifying progress during 1924. In February of that year the Senate and Council of the University approved a new scheme for undertaking the pathological work of the Leeds Union Infirmary, and Professor M. J. Stewart was appointed consulting pathologist. Since 1918, when the original agreement was made with the Infirmary Board, there has been a steady increase in the amount of this work, resulting in some interference with research. In the annual report of the department for 1924 attention is drawn to the Medical Research Council's recent criticism of routine work in university laboratories, to which reference was made in the *JOURNAL* of February 14th, 1925 (p. 319). Professor Stewart does not agree with the suggested separation of routine work from research recommended by the Medical Research Council; he considers that the routine work only requires more adequate staffing and accommodation for it to provide good training for junior members of the university and prevent research work from becoming divorced from clinical practice. Professor J. W. McCleod, Brotherton professor of bacteriology and city bacteriologist, also commenting on the Medical Research Council's strictures, insists on the importance of providing an adequate stream of material through the department for research and teaching purposes. He agrees that the treatment of members of pathological and bacteriological departments of universities generally has not been altogether fair, and considers that the remuneration of the younger members of the staff should be higher. He believes that with a sufficiently large and well paid staff the system of combining routine work with research does not call for immediate change, and that so long as the financial position of the country is difficult this handicap of the university is not unreasonable. Research work undertaken during the year includes the study by Professor Stewart of the morbid anatomy of gastric and duodenal ulcer, with special reference to the question of the relation, if any, between simple chronic ulcer and cancer. A new method of estimating urea in blood, devised by the late Dr. Wyon, lecturer in pathology in Leeds University, has now been perfected and is in regular use. Dr. Forweather and Mr. G. A. Collinson are working on a new clinical method for the estimation of iodine in blood, in connexion

with the physiological distribution of thyroid secretion. The value of the Wassermann test as performed in Leeds has been compared with methods in use elsewhere, and the conclusion reached is that only slight modifications of technique are required to bring the Leeds Wassermann results to the highest possible degree of sensitiveness and accuracy. Dr. H. Ross and Dr. Gordon, who have been investigating respectively the bactericidal action of oils and fats on bacteria and the inhibition of bacterial growth of amino-acids, have received grants from the Medical Research Council and the British Medical Association; and grants have been made also to Professor Stewart and Mr. P. J. Moir. During the year a collection of x-ray apparatus has been installed, and valuable results have been obtained by radiological examination of pathological specimens. Many of the photographs have been used for teaching purposes.

#### SLEEPING SICKNESS CONFERENCE.

THE International Conference on Sleeping Sickness, the opening of which by the Under Secretary of State for the Colonies was recorded last week (p. 976), has made a series of recommendations. The most important of these is that an international commission should be set up to continue and promote in equatorial Africa the investigation of certain problems which at present await solution. Among these are the existence of any human immunity against trypanosomiasis and the comparative value both from the curative and prophylactic point of view of trypanocidal agents; the part played by wild and domestic animals as breeding places for the virus; the relations between trypanosomiasis due to *T. gambiense* and *T. rhodesiense* respectively; and the effect of precipitins applied to the blood in the alimentary canal of the tsetse fly. These subjects are already being investigated in various national institutes, and it is suggested that great advantages would flow from co-operation between them and the co-ordination of work now in progress. Uganda and the regions in the neighbourhood of Lake Victoria are thought to be the territory most suited for the study of the problems enumerated. The Conference has recommended that the local international commission should be presided over by Dr. H. L. Duke, bacteriologist to the Uganda Government, under whose guidance valuable researches have been carried out in the laboratories at Entebbe. Extensive field work has already been done by the medical services of Uganda and by the administrative officers of the adjoining territory of Tanganyika. The Conference has recommended that, in addition to a few workers from the institutes of African Powers, the commission should include a biochemist and entomologist with local knowledge, and that the collaboration of Dr. Kleine should be invited. It has suggested also that the commission should meet at Entebbe at the end of this year or in January, 1926, and twelve months later present a special report to the League of Nations expert committee. After studying the research methods at the Entebbe institute and its field laboratories, as well as the field work and measures taken against sickness in Uganda and Tanganyika, the commission would examine the methods for the control of the tsetse fly Mr. Swynnerton has instituted in the Tanganyika Territory. Other recommendations of the Conference laid stress on the need for periodic official conferences between the administrative and medical officers engaged in the campaign against sleeping sickness on both sides of the boundaries between infected countries. It advises also the institution of a system of sanitary passports for the native population in the infected areas, and wherever practicable the plan of establishing areas freed from population on both sides of the frontier in order to facilitate the control of native traffic. Special agreements, it considers, should be made

between local administrations to allow of rapid and regular interchange of all epidemiological intelligence and information, that the recommendations of the chief of the medical service in sleeping sickness areas should be binding on the local administrations, and that in such areas the medical officers should have magisterial powers regarding the application of measures in connexion with the campaign. The need is emphasized of providing a medical and health service, including medical officers and auxiliary staff proportionate to the number of the population infected and the extent of the district to be inspected, and of adequate administrative staffs, particularly in the neighbourhood of frontiers. Attention was drawn also to the necessity of uniform methods for recording statistics relating to the morbidity and mortality of sleeping sickness, and of preparing maps showing the prevalence of the disease, the sites of the sleeping sickness camps, the sectors of prophylaxis, and the distribution of the various species of glossinae. These subjects are to be studied and recommendations, including one for a uniform system of laboratory diagnosis, made to the Health Committee of the League of Nations for submission to the Governments concerned. It is estimated that £10,000 will be required, but this would include the salaries of local scientific personnel, the foreign members and laboratory assistants, as well as travelling and other general expenses. The delegates of the various Governments present at the Conference were asked to move their Governments to contribute to a common pool, but it is anticipated that the Governments will continue to pay the salaries of the medical officers and other workers who take part in the work of the commission. The Conference also strongly recommended that the Governments should obtain for 1926 a credit balance of at least £5,000 from the Health Organization of the League of Nations, and it is hoped that funds may also be provided by the scientific research organizations of certain countries.

#### BRITISH ASSOCIATION, SOUTHAMPTON, 1925.

THE preliminary programme for the annual meeting of the British Association, to be held at Southampton from August 26th to September 2nd inclusive, has been issued. The inaugural general meeting will take place in the Central Hall on Wednesday evening, August 26th, when Professor Horace Lamb, F.R.S., will assume the presidency of the association in succession to Sir David Bruce, and give the presidential address. The sections and their presidents this year are as follows: A, Mathematics and Physics, Dr. G. C. Simpson; B, Chemistry, Professor C. H. Desch; C, Geology, Professor W. Parks; D, Zoology, Mr. C. T. Regan; E, Geography, Mr. A. R. Hinks; F, Economic Science and Statistics, Miss Lynda Grier; G, Engineering, Sir Archibald Denny; H, Anthropology, Dr. T. Ashby; I, Physiology, Professor A. V. Hill; J, Psychology, Professor C. Spearman; K, Botany, Professor J. Lloyd Williams; L, Educational Science, Dr. W. W. Vaughan; M, Agriculture, Dr. J. B. Orr. Among the items in the provisional programme of addresses, discussions, etc., we may note the following: August 27th, discussion in the Educational Science Section on "Health in schools, epidemics and dietary"; conference of delegates of corresponding societies presided over by Sir Daniel Hall. August 28th, presidential address by Dr. Vaughan, headmaster of Rugby, on the warp and woof in education; lecture by Mr. J. E. Barnard on the observation of the infinitesimally small. August 31st, presidential address by Professor Desch on the chemistry of solids, Professor Hill on the physiological basis of athletic records, and Dr. J. B. Orr on the inorganic elements in animal nutrition; joint discussion by Educational and Zoological Sections on the teaching of biology in schools. September 1st, joint discussion by the Sections of Physiology and Psychology on

the acquisition of muscular skill. During the meeting a series of public lectures to citizens and their children will be given by members of the association. The annual meeting of 1926 will be held in Oxford under the presidency of H.R.H. the Prince of Wales.

#### THE "BRITISH MEDICAL JOURNAL": NEW ADDRESS.

Our present issue is the last to be printed at 429, Strand. During the Whitsun holidays the Editorial and Printing Departments of the *BRITISH MEDICAL JOURNAL* will be removed to the new headquarters building of the British Medical Association in Bloomsbury. Henceforward the postal address for all communications intended for the Editor will be "*BRITISH MEDICAL JOURNAL, British Medical Association House, Tavistock Square, W.C.1.*" the telephone number of the Editorial Department will be *Museum 9864*, and the telegraphic address "*Aitiology, Westcent, London.*" Until further notice is given in these columns, all communications with reference to advertisements, as well as orders for copies of the *JOURNAL*, should continue to be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2. It is expected that the Medical Department and the Library of the Association will be removed about June 17th, and the Finance Department about June 19th.

#### LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual general meeting of the London and Counties Medical Protection Society, Ltd., was held on May 20th, under the chairmanship of Sir JOHN ROSE BRADFORD.

The report of the council stated that the number of applications from members asking for advice and assistance in 1924 was 785; in the large majority of cases satisfactory results were obtained without litigation. The case of outstanding importance in which the society had been concerned was that of *Harnett v. Bond and Adam*, in which the society bore the whole of the expenses of the defence of its member, Dr. Adam. Hitherto provision by the society of an amount not exceeding £3,000 for defraying any damages awarded against a member, together with costs allowed to the other side, had been more than adequate; but it became evident that any such limit might be exceeded in exceptional cases such as this one, and the council therefore at once made provision by insurance for an unlimited amount, so that members could be completely indemnified in all circumstances. During the year the society was required to spend £8,244 on legal proceedings; of this amount, £6,331 represented the cost of actual defence of members, and £1,913 went in payment either of adverse costs and damages awarded in cases which were unsuccessful or in settlement of claims when this was thought advisable. Of the £6,331 spent in defence of members only £31 was actually recovered from the other side in cases in which the society, having been successful, was awarded costs, but in addition to this small sum an amount of £2,434, representing the costs recovered in the *Harnett* case on the favourable decision by the Court of Appeal, was held in suspense pending the result of the appeal to the House of Lords, and now about £1,867 of that amount would be brought into the society's account for the present year. A report by the society's solicitors (Messrs. Lo Brasseur and Oakley) was appended to the report of the council, and contained particulars of many interesting cases, including what has become known as the "*£1,000 fine*" case under the National Insurance Act.

Sir JOHN ROSE BRADFORD, in moving the adoption of the report, said that much of the work of the society was undertaken, over and above the defence of individuals, for the benefit of the profession as a whole. He had heard it objected against the society that it possessed a large amount of accumulated funds, and therefore could not have been so liberal in its expenditure on defence as it might have been.

But if it had not been for the fact that the society had these large accumulations an action such as the *Harnett* case could not have been successfully undertaken and carried through from the lowest court to the highest. He thought the society was to be congratulated on being able to meet this very large call out of its own hard cash; the expenses were not met in any indirect way by insurance, but were actually paid out of the society's assets. The society had had a larger accession of members than in previous years; the number who joined last year was 1,142, and of these 436 were men in the first year of their qualification. The number of medical practitioners in London, the provinces, and Wales was 28,400, and of these the society included in its membership slightly under one-third, and, of course, had many members of the dental profession in addition.

There was a scheme on foot, Sir John Rose Bradford continued, for starting another defence society. It would be premature for him to discuss that matter, but he did wish to say that it could not be seriously urged that there was any reason for the institution of a third society, connected directly or indirectly with the British Medical Association, on the ground that the existing societies did not perform their work efficiently. Every society had some members who were dissatisfied, but in the "*London and Counties*" there was extremely little evidence of such dissatisfaction. It was the exceptional thing to have any complaint, or even any criticism, of the way in which the affairs were conducted; and the same thing, he knew, applied to the other great defence society.

The report was unanimously adopted, and with many expressions of appreciation Sir John Rose Bradford was re-elected to the presidency, and Dr. C. M. Fegen to the treasurer'ship. Dr. Fegen said that it was worth while to recall the fact that the members of the society had never been compelled to appeal to the profession as a whole for contributions to pay for costs or damages in cases which had been won against them. They had never had to go to the larger circle of the medical profession or to the general public, cap in hand, for help in an unfortunate dilemma.

The vice-presidents, retiring members of council, and other officers were all re-elected.

#### ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

##### *Evidence of National Council for Mental Hygiene.*

At the sitting of the Royal Commission on Lunacy and Mental Disorder on May 22nd evidence was tendered by Dr. E. Farquhar Buzzard, Dr. H. Crichton Miller, and Dr. R. Worth, on behalf of the National Council for Mental Hygiene.

Dr. FARQUHAR BUZZARD explained that the council was of recent institution, and its purpose was the co-ordination of the various associations interested in mental hygiene, and the furtherance of the education of the public in this respect. The council, in a memorandum prepared for the Commission, urged that the treatment of mental disorder should be brought within the fold of general medicine. The segregation of mental cases in institutions divorced from general hospitals created an impression that mental illness was something quite different from bodily, and, on the other hand, owing to the conduct of some patients general hospitals were not suitable for the treatment of certain forms of mental disorder. Facilities for early treatment should in those cases be provided at local clinics separate from either mental or general hospitals. The council had attempted to arrive at some idea of the number of persons in the early stages of mental disease. From the report of the Prison Commissioners it appeared that in a recent year 1,842 prisoners were remanded for report on their mental condition, and, in addition to these, 134 were certified insane during sentence, 227 were found insane on remand, and 55 were found insane at the time of trial. These 416 persons who were definitely found insane had broken the law while in the incipient or early period of insanity, and they were people for whose treatment at present there was entirely inadequate provision. Suicides, again, in a recent year, numbered close upon 4,000, and mental instability entered to an unknown extent into the problems of illegitimacy, dependency, vagrancy, and alcoholism. Still another class of early mental sufferers had now to be reckoned with—the increasing number of those who had encephalitis lethargica. The council had recently sent out a questionnaire to 237 of the more important hospitals and

infirmaries in Great Britain asking what facilities were available for the treatment of mental disorder, and of the 159 institutions which replied 135 stated that they had no provision of any description, and of the 24 who had some form of provision only 5 afforded in-patient treatment. The recommendation of the council was that skilled treatment for mental disorders in general hospitals, or when the general hospital was unable or unwilling to undertake the work, in special institutions. The work, in association with a hospital, should be carried on in a completely separate building, but the organization should approximate as closely as possible to the voluntary hospital principle, and there should be no compulsory detention. Voluntary boarders should be allowed in all county and borough mental hospitals, and the council was in agreement with the British Medical Association as to the desirability of extending the voluntary boarder system to rate-aided institutions. With regard to the provision of early treatment for those who could pay, it was of opinion that medical practitioners should be allowed to treat willing and non-volitional patients without certificates in registered nursing homes or kindred institutions, but wherever non-volitional cases were received some form of notification to or supervision by the central authority was desirable. To protect patients and to maintain the principle of bringing this treatment into line with general medicine, the registration of all nursing homes was urged. The council deprecated any special registration of homes on the ground simply that the condition of the patients was thought to have a mental rather than a physical basis. If nursing homes of every type were registered abuses could be dealt with by the ordinary processes of law, and patients suffering from mental disorder could have the freest choice as to where they wished to be treated.

The suggestion that all nursing homes should be registered was questioned by members of the Commission. Lord Russell thought that any necessary supervision of nursing homes could be better undertaken by a medical body than by the State.

The CHAIRMAN (Mr. H. P. Macmillan, K.C.) asked for the views of the council on the medical superintendent and his duties. Dr. WORTH urged that a mental hospital must be under one head, and that head a medical man. He had known a case in which a medical superintendent had his responsibility shared by a director of administration, but there was inevitable collision. The one medical head was necessary because the whole régime of the institution was part of the treatment. Dr. WORTH also favoured a system whereby the patient's medical practitioner could follow the patient after he had entered the institution; this would furnish another of the desirable points of contact between the institutional patient and the outside world.

Dr. CRICHTON MILLER urged that the Board of Control should be empowered to act in a consultative capacity in doubtful cases. At present the members of the Board were personally helpful in such cases, but this did not come within the terms of the legal constitution of the Board. If the Board were allowed to advise, it would free the practitioner's mind from certain doubts as to legality, and enable him better to concentrate on treatment.

#### *Mental Hospital Chaplains.*

The Bishop of CHELMSFORD and the Rev. W. E. BARNES (chaplain at Hanwell and Cane Hill) gave evidence as to the functions and status of the mental hospital chaplain. Mr. Barnes said that at Hanwell there were about 100 communicants. He felt that his ministrations were specially helpful to sufferers from religious mania. In his experience he had never seen any instance of punitive or vicious ill usage, though he had seen patients suddenly become violent and require prompt restraint.

#### *Offences against the Act.*

Sir ARCHIBALD BODKIN, K.C., indicated certain desirable amendments of Section 315 of the Lunacy Act, which deals with the offence of receiving or retaining a lunatic or alleged lunatic otherwise than in accordance with the Act, and with taking charge of such persons for payment in an unlicensed house. He indicated how the distinct offences and the appropriate penalties might be more clearly set out, and said that a more precise wording of the clause relating to detention would be, "Any person who permits, or is party to, the continued residence of a lunatic or alleged lunatic," etc. The present legal provisions did not cover the voluntary patient, who did not go as a lunatic or an alleged lunatic.

#### *London County Council's Evidence.*

The London County Council is proposing to give evidence to the Royal Commission to the effect that if power is given on the lines of the Mental Treatment Bill for temporary treatment in approved institutions to uncertified persons suffering from mental disorder, it is desirable that the provision of this accommodation should be the work of the same branch of the local authority's

administration as that which has to do with the administration of the mental hospitals. To remove from the Mental Hospitals Committee the making of the necessary arrangements for the care and treatment of incipient cases would tend, in the Council's opinion, to lower the status of the mental hospitals, and would result in much inconvenience in administration. It is also to be urged that in every case in which an order for compulsory detention of a person of unsound mind is made it should be necessary for two medical certificates to be presented to the judicial authority for the order, one of these certificates to be given by a practitioner who has been approved specially for that purpose. It was reported to the last meeting of the London County Council that the total number of insane patients for whose accommodation in ordinary mental hospitals the Council was responsible on January 1st was 19,060 (7,779 males, 11,281 females), as compared with 18,918 a year previously. In addition there were 213 insane persons in Poor Law institutions, 81 boarded out with relatives or friends, and 4,976 of the chronic, harmless kind, in the institutions of the Metropolitan Asylums Board. In these last categories there was a total decrease of 190 as compared with the previous year.

## Scotland.

### LORD HIGH COMMISSIONER AND EDINBURGH HOSPITALS.

THE High Commissioner, Lord Elgin, who was accompanied by Lady Elgin, paid a series of visits last week, as representative of the King, to Edinburgh hospitals. On May 21st the Deaconess Hospital of the Church of Scotland was visited. Lord Sands, Chairman of the Board, in receiving their Graces, said that the hospital, which had now existed more than thirty years, had been supported by the whole Church of Scotland, and in a special degree by the Women's Guild of the Church, and during this period it had been continuously successful. On the same day their Graces visited the Royal Blind Asylum, where they were received by the chairman, the Rev. Dr. Burns. They visited the workshops, where, in particular, the operations of basket making, knitting with modern knitting machines, and piano tuning are carried out by the blind. In this connexion it was mentioned by the chairman that they were received by the chairman, the Rev. Dr. Burns. In the preceding year seven pupils of the Blind Asylum had passed the examination of the Incorporated Society of Musicians with honours, and two with distinction. Several of the pupils had taken degrees in different Scottish universities. Lord Elgin impressed on those present the necessity for making the very best possible use of the gifts they had, since so many blind workers were doing splendid work despite loss of sight. On May 20th their Graces visited the Royal Infirmary and distributed prizes to the nurses. Lord Elgin, in expressing the pleasure it gave him to visit the Infirmary and to see the useful work which was being done by the aid of the nurses, remarked that the profession of nursing was probably one of the highest ideals that a woman could have. His Grace announced that out of a trust founded by the late Sir James Affleck, an annual scholarship of £30 was to be offered for a course of training in midwifery to be awarded to a nurse by competitive examination.

### AFTER-CARE OF MENTAL DEFECTIVES.

The first annual conference of the Scottish Association for Mental Welfare was held in Glasgow on May 8th. Lord Murray, president of the association, who was in the chair, congratulated the members of the association on having established an institution which had already obtained the approval of the statutory bodies and authorities with whom it co-operated. The Board of Control and the Secretary for Scotland had recently given an assurance that the extension of institutional accommodation for mental defectives in Scotland would receive early consideration, and that the expenditure of further capital by local authorities would be favourably considered. A paper was read by Dr. Hamilton C. Marr, one of the Commissioners of the General Board of Control for Scotland, on how continuity of care for the mental defective could best be secured. The association would be greatly helped by an enactment which would enable it to prepare a list of mentally defective persons who were no longer attending special classes and schools under the education authorities, and for whom, on account of financial circumstances or objections by parents and relatives, parish councils undertook no further respon-

sibility. The problem of the mentally defective child presented the greatest difficulties at the age of 16 and when the defective person was approaching the age of 21; for, apart from a few cases requiring temporary or permanent hospital care, the system of education must be continued, and this could only be done in industrial colonies of the closed or open type. Dr. Robert Hughes, school medical officer, Stoke-on-Trent, said that the most difficult cases for adequate supervision were the feeble-minded of higher grades of intelligence but of pronounced temperamental instability. It was an extraordinary paradox that the type of defective who tended to become an intolerable nuisance to society was the one whose training had been least neglected. He did not think that the stabilizing of unstable characters could be carried out with success in any type of day school; some form of residential institution was essential. Dr. Cruickshank, medical officer of the Scottish Board of Health, said that the fundamental requisite in any scheme for continuity of care of mental defectives was first of all completeness of ascertainment followed by accuracy of classification. It might be worth while to consider whether school medical officers could not be induced to take up these questions of ascertainment of mental deficiency and its classification. Sir H. Arthur Rose, D.S.O., chairman of the General Board of Control for Scotland, who presided at the afternoon session of the conference, said that a short time ago, in giving evidence before the Royal Commission on Lunacy and Mental Disorder, which was considering English lunacy administration, he was asked what steps had been taken in Scotland to develop an association on the same lines as the English Association for Mental Welfare, and he had been very glad to be able to reply that this association had been started. Lord Ashmore, president of the Scottish Justices' and Magistrates' Association, said that the feeble-minded were contributing in an ever-increasing degree to the social deterioration of the community. The Legislature had made an effort to minimize the evils by the Mental Deficiency Act of 1913 and by certain education Acts, but, unfortunately, owing to financial considerations legislation had not been carried into operation. Legislation, however, had fallen far short of meeting the demand, because it had not yet recognized the fact that feeble-mindedness endured through life, that it could never be cured, and that from birth till death the feeble-minded required to be looked after and protected. It was urgently necessary in the interests of the feeble-minded and of the public that there should be industrial colonies in which the feeble-minded would be segregated except those cases which were suitable for boarding out.

#### VOLUNTARY ADMISSION OF THE INSANE TO ASYLUMS.

At a meeting of the Edinburgh Women Citizens' Association in Edinburgh on May 15th, an address was given by Dr. W. M. McAlister, deputy physician-superintendent of the Royal Asylum, Morningside. Sir John R. Findlay, K.B.E., presided, and said that not very long ago insanity was generally regarded as a sort of affliction arising no one knew how and to be treated only by restraint in some form or other. As long as that was the only method of dealing with insanity it was necessary to safeguard the rights of the subject, and he was afraid that at the present time the legal position was distinctly behind the medical position. Dr. McAlister referred first to the treatment of mental defectives. Life-long care of the mental defective was necessary, not only for his own sake but for the sake of society as a whole; it was a great mistake to turn defectives loose on the community at the very time when their capacity for injuring the social fabric was about to reach its zenith. Public opinion, he said, must be shaken out of this short-sighted policy, and he commended the Women Citizens' scheme for establishing a colony for the permanent care of the feeble-minded. Apart from mental defectives, a large percentage of mentally diseased people were amenable to treatment, and it was a fallacy to presume that mental disorder must necessarily be permanent or must recur. In Scotland practically all the asylums were under disinterested management, and no individual secured any financial advantage by the detention of a patient. Due care was now taken to see

that a patient was really desirous of being admitted to an asylum; and the physician-superintendent regarded his relations with the voluntary patient as being in the nature of a contract between two parties, and satisfied himself that the patient accepted the conditions imposed upon him in his capacity as a voluntary patient. At the Royal Asylum, Morningside, the voluntary admissions had in recent years always been over 50 per cent. of the total admissions. Unfortunately, at present this privilege of voluntary admission was denied to patients supported by the rates; there ought to be one arrangement only, whether the patient were rich or poor. In conclusion, he said that all who were engaged in this type of work welcomed the spirit of public interest which had been so obvious of late.

#### POST-GRADUATE TEACHING IN GLASGOW.

The Glasgow Post-Graduate Medical Association has arranged a general medical and surgical course to be held during the last two weeks of August and the first two weeks of September. In the mornings general medicine, surgical diagnosis, and minor surgery will be taught in the Royal Infirmary and in the Victoria Infirmary, and in the afternoons special subjects will be dealt with in the various special hospitals, or in the special departments of the general hospitals, two subjects being treated each afternoon. On the four Saturday mornings there will be classes in tuberculosis and infectious diseases at Ruthill Fever Hospital. The inclusive fee for this course is £10 10s., or alternatively £6 6s. for either the first or second fortnight. Besides this course certain special classes have been arranged in several hospitals to suit the requirements of general practitioners who have but little time to spare for hospital work. In June morning classes in clinical surgery and dermatology will be held, in June and July classes in clinical gynaecology and dermatology, and from the middle of September to the middle of October classes in diseases of the throat and nose, radiology, and venereal diseases have been arranged. Intensive courses are also announced at the Royal Hospital for Sick Children, the Glasgow Eye Infirmary, the Glasgow Royal Maternity and Women's Hospital, the Royal Samaritan Hospital for Women, and the Ear, Nose, and Throat Hospital. Clinical assistantships will be available at various hospitals during the summer months; candidates for these are expected to enrol for a period of three months, and be prepared to devote to the work either the whole or part of the day, according to the terms of the particular assistantship. Further information may be obtained from the Secretary, Glasgow Post-Graduate Medical Association, the University, Glasgow.

#### DUNDEE INFIRMARY EXTENSION.

An extension of the Caird Pavilion of Dundee Royal Infirmary was formally opened on May 15th by Mrs. Marryat, who gave £25,000 for its cost. The extension consists of two operating theatres and a medico-electrical and radiological department of the most modern kind. Mr. Drummond Taylor, chairman of directors, presided. Sir John W. Thomson-Walker, F.R.C.S., said that it was now thirty years since he had been a resident in Dundee Infirmary, and at that time there was only one operating theatre, which had been constructed by walling off the end of a corridor. That theatre had served 176 beds, and he did not think anyone who had not gone through such an experience could tell how exhausting it was to stand four or five hours operating in an inadequate theatre. The extension provided for the surgeons all the means by which they could produce the best work for the patient. Within the past thirty years surgery had become greatly specialized, and in some ways this had been of enormous advantage, for the surgeon could observe the same kind of cases time after time, and could learn more about one special type than before. There was, however, a disadvantage in specialization in that the surgeon was a little apt to go along one narrow line and to forget that the whole body was an interchanging mass. No specialist in surgery could, therefore, do without the general surgeon, just as the medical specialist could not do without the general physician.

## Ireland.

### HEALTH INSURANCE AND THE MEDICAL SERVICES.

#### *Proposed Amalgamation of Approved Societies.*

THE Committee on Health Insurance and Medical Services in its interim report, to which reference was made last week (p. 981), recommends that county insurance committees be abolished and that the approved societies should be amalgamated. From this view, Dr. Rowlette, the representative on the Committee of the Irish profession, dissents, and puts forward a counter-proposal that the whole system of insurance should be nationalized, and should be administered by a State department. He sees in the proposal for a unified society certain dangers:

(1) A society comprising in its membership all the insured persons in the Saorstát would be a formidable commercial combine, so large and so powerful that it would be beyond the control of either the official supervising authority or of the Oireachtas. It would be to the interest of such a combine to gain a power over each of the parties of the State, and to attempt to pervert Government at its source. So far from the diversity of elements in the society tending to prevent its exercising a political power, the fact that it contained very diverse elements would give it all the greater power in the underworld of politics.

(2) The farming out of health insurance to a society created for the purpose appears to be a mere shelving of the responsibility belonging to the State itself. In the words of one of the most experienced witnesses who appeared before us, "Unification would be nationalization without responsibility."

(3) All the evidence put before us by, or on behalf of, insured persons was definitely against the scheme of a unified society, though some witnesses were willing to accept it as a step towards nationalization. The opposition to the latter was much less than to unification, even on the part of those who opposed any change in the present system.

Among some minor reforms as regards national health insurance, a majority of the Committee recommends the abolition of insurance committees and the transference of the care of the tuberculous insured to the local authority.

In regard to the second term of reference, the question of the provision of a system of medical treatment for the insured, the Committee (Mr. McElligott dissenting) accepts the views expressed by the Committee on Medical Benefit (1913) and by the Irish Public Health Council, that medical treatment on a contributory basis should form part of national health insurance. No scheme is put forward, but the Committee goes on to say:

"The provision of medical benefit is mainly a problem of finance. The Committee, in the absence of fuller information as to the funds that may become available from insurance sources (in addition to those at present devoted from various sources to purposes of medical treatment), and as to the position which such arrangements would occupy in relation to the medical charities system, is unable in this interim report to formulate a scheme for the provision of medical treatment. It is hoped, however, that the valuation of the approved societies, the preliminary operations of which are at present proceeding, will be sufficiently advanced by the autumn of this year to enable us to make definite recommendations on the second—as well as on the third—of our terms of reference. Meanwhile we have appointed five of our members as a subcommittee to pursue investigations as to the lines on which schemes for medical treatment might be appropriately laid, due regard being had to the system obtaining at present for the medical relief of the poor. With the outcome of these inquiries before us, the consideration of the financing of it in the light of the valuation results will, it is hoped, be expedited. Under the third term of reference the Committee reviews the present condition of the public services, preventive and curative."

In regard to the salaries paid to dispensary medical officers, the Committee (Mr. McElligott dissenting) states that it accepts the following criticism:

"The salaries of dispensary medical officers, first fixed in the middle of the last century, remained almost unchanged up to the beginning of the present century, in spite of greatly increased cost of living and of the longer course of education required in order to become a medical practitioner. In 1904 the average salary of a medical officer in Ireland was £109. There was a slight gradual increase during the following ten years, and in 1914 the average had become £130. The average salary in the Saorstát is now £251, a sum which does not show much, if any, advance as regards purchasing power on the salary paid in 1904."

The Committee also recommends that "study leave" for a period not less than three months should be granted at least as often as once in every five years, and that evidence of having taken advantage of such opportunities should receive consideration where promotion is in question. During "study leave" the medical officer should, subject

to regulations, receive full salary without deduction for payment of a locum-tenent: a grant might be provided to cover fees for study. The Committee quotes with approval the recommendations of the Majority and Minority of the 1913 Committee regarding a national medical service, and also the similar recommendations of the Irish Public Health Council. It defers any definite recommendation on this point pending the result of the valuation of the approved societies now in progress. It however expresses the hope that the subcommittee will consider the entire matter in the light of both past reports and of existing conditions, and thus, it is hoped, will enable the Committee to frame a comprehensive scheme which, under some form of national medical service, will combine the medical treatment of the insured with the medical treatment of the poor.

### MENTAL HOSPITALS IN NORTHERN IRELAND.

The second report of the inspectors of lunatics (Northern Ireland) covers the year 1923, and contains several statistical appendices. No marked change in the numbers of patients under treatment occurred during the year; the total number at the end of the year was 4,291, as compared with 4,277 in the previous year; the males increased by 42, but the females decreased by 28. The general arrangements for treatment of mental disorders in Northern Ireland were described in our issue of May 24th, 1924 (p. 931), and no change has been made in them since. The number of insane inmates of workhouses in Northern Ireland has decreased from 222 in 1922 to 204 in the year under review: in a few instances patients were found for whom asylum treatment was required.

## England and Wales.

### LEICESTER PRIVATE HOSPITAL.

THE new Leicester private hospital, which has been presented by Mr. T. Fielding Johnson, J.P., late chairman of the Royal Infirmary, was opened on May 20th. The hospital at present contains fifty beds, and when more accommodation is needed it will be possible to increase the number to sixty, or even sixty-five. In addition to beds reserved for medical and surgical cases, eight beds on the top floor are provided for maternity cases. A few rooms contain two beds, the majority one only. The general equipment is of the most modern kind: a large electric lift serves each floor; hot and cold water is laid on in every bedroom, and alternative heating by hot water radiators and electric heaters is available. Certain rooms, such as the operating theatre, are specially equipped in order to obtain higher temperatures than the average when required, and heated racks have been installed on each floor for keeping various utensils warm. Special departments, including a good x-ray room and a pathological laboratory, are provided. A nurses' duty room is placed on each floor, and contains an electric stove to enable hot food to be prepared at any hour. The patients will be attended by their own medical practitioners, and full telephone facilities have been established. There are two operating theatres, one equipped for eye work. The institution was originally three separate residences, which have been combined. Leicester has thus obtained a private paying hospital quite independent of the Infirmary. It will be administered on hospital lines by a representative committee, affording as far as possible the advantages of a voluntary hospital, and enabling any medical practitioner to treat his own patients under the most modern hospital conditions, with the aid of any consultant whom he may desire. After the opening ceremony a reception was held by Dr. T. V. Crosby, president of the Leicester Medical Society.

### INFECTIOUS DISEASES IN SWINDON.

During the twelve months ending March 31st, 1925, the incidence of scarlet fever in the Swindon district was extremely low, only seventeen cases of this disease, together with three cases of scarlet fever complicated with

diphtheria, requiring treatment. This represents the lowest number of patients with scarlet fever ever treated in one year at the Swindon and District Isolation Hospital, being less than a quarter of the next lowest figure, and less than one-tenth of the average; the type of disease was, however, severe. The number of diphtheria patients treated was considerably higher than usual, but the disease was mild. The proportion of patients received from the borough of Swindon was unusually low. The new administrative arrangements at the hospital enabled a large number of diseases to be treated other than those previously considered suitable for accommodation in an infectious hospital, and in this way considerable economies were possible. These diseases included pneumonia, puerperal fever, erysipelas, and nerve diseases. No case of cross-infection of any kind occurred during the year among the patients, and no return case had to be investigated. In his annual report the medical superintendent, Dr. Dunstan Brewer, suggests that it may be advisable in future to deal with other diseases, such as rheumatic fever, influenza, or with infantile diarrhoea. The old idea of reserving wards for a single infection, and leaving them empty when not required for this particular infection, has now been abandoned.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

In the House of Lords on May 21st, in the course of a debate on land and labour in Kenya, the Earl of Balfour, Lord President of the Council, said that the Government proposed to set up a body resembling the Committee of Imperial Defence to investigate civilian problems, which were becoming more and more insistent in connexion with imperial development. The problems which were arising must be dealt with in a wider spirit and with a greater command of scientific methods than were now at disposal. Such a body would have an immense use as a clearing house of the nation as well as an instrument for acquiring new knowledge.

The House of Commons adjourned on May 28th till June 9th, having read the Finance Bill a second time by 331 to 139 and having discussed the Ministry of Pensions Vote and the claims of ex-ranker officers. Members of Parliament who favour the claim of the osteopaths to statutory registration met on May 26th to arrange for a deputation to the Minister of Health, who will probably see them on June 9th. On May 25th the Minister of Health conferred with the Unionist Health and Housing Group at the House of Commons. Dr. Fremantle presiding.

The Government is understood to desire that Mr. H. A. L. Fisher should become chairman of the promised Committee on Nurses' Registration, and in view of his other engagements the appointment of this Committee may be postponed. On May 25th, on the motion of Sir Leslie Scott, the House of Commons passed the Mental Deficiency (Amendment) Bill through committee and third reading without debate. It now goes to the Lords, and has a good prospect of becoming law this session.

**The Powers of the General Medical Council.**—Mr. Basil Peto asked the Minister of Health whether he would consider amendment of the Medical Act, 1858, to give a right of appeal to medical practitioners struck off the Register by decisions of the General Medical Council holding them guilty of infamous conduct. Mr. Chamberlain replied that he was not aware there was any general demand among the medical profession for the amendment of the Medical Acts in the direction suggested, and in the absence of general agreement he was not prepared to introduce legislation. In a supplementary question Mr. Peto asked whether the Minister thought that the absolutely autocratic power over the lives and careers of the whole of the medical profession given to the General Medical Council by the Medical Act of 1858 required some revision. Sir Henry Craik intervened to ask whether it was not the experience of the Ministry of Health that the action of the General Medical Council had been highly expedient in the interests of health and of the community generally. Answering Mr. Peto, Mr. Chamberlain said that if there were any general feeling among the members of the profession that the powers of the General Medical Council were excessive, he would have no difficulty in ascertaining it. Medical men had not generally been backward in putting forward any grievance they might have.

**"Manipulative Surgery."**—Mr. Basil Peto asked Mr. Neville Chamberlain whether, in the interest of public health, he would consider legislative action to ensure that persons qualified to give practical instruction in manipulative surgery should have the opportunity of giving it and also of obtaining degrees in this

branch of surgery. Mr. Chamberlain said that under the revised medical curriculum adopted by the General Medical Council in 1922 practical instruction in manipulative surgery could be and was given by persons holding registrable medical qualifications. As at present advised, he was not prepared to recommend legislation for the purpose of establishing degrees or diplomas for persons who had not satisfied the statutory requirements of the General Medical Council.

**Small-pox and Vaccination.**—In reply to Mr. Broad, Mr. Neville Chamberlain gave the ages of the thirteen persons registered in 1924 as dying from small-pox, with the other diseases, if any, mentioned on the death certificates. These deaths were: 10 months, small-pox, marasmus; 15 months, whooping-cough, broncho-pneumonia, small-pox; 9 months, small-pox, convulsions; 15 years, small-pox; 2 months, variola; 24 days, small-pox; 22 months, small-pox, measles, convulsions during convalescence; 14 years, eretism from birth, valvular heart disease, dropsy, small-pox; 28 days, congenital debility, variola; 36 years, haemorrhagic small-pox; 7 years, haemorrhagic small-pox, cardiac failure; 39 years, the same; 52 years, pelvic abscess, small-pox. Mr. Whiteley asked the Minister of Health whether modern methods of vaccination tended to produce faint marks which sometimes disappeared. Mr. Chamberlain said he was advised that the marks produced by modern methods of successful primary vaccination seldom disappeared. Mr. Whiteley asked whether the medical officers of the Ministry based their classification of the vaccinal condition of small-pox cases on the presence or absence of the vaccination marks. Mr. Chamberlain, in reply, gave the five headings under which the chief medical officer of the Ministry classified small-pox cases. One heading was "stated to have been successfully vaccinated, but no vaccination cicatrix present." In reply to Mr. Lee, Mr. Neville Chamberlain said that there were approximately 3,514 public vaccinators in England and Wales; 15 were paid by salary and the rest by fees. Separate information was not available on the number or cost of vaccinations performed by them. Medical officers of Poor Law institutions who were also public vaccinators for such institutions numbered 692, of whom 11 received salaries for this work.

**Deaths from Infectious Diseases.**—In reply to Mr. Rhys Davies, Mr. Neville Chamberlain supplied the following table:

Year.	Influenza.	Scarlet Fever.	Measles.	Whooping-cough.	Cholera-pox.	Epidemic typhus.	Small-pox.
1915	10,481	2,406	16,445	8,143	92	—	13
1916	8,791	1,381	5,413	6,075	65	—	18
1917	7,229	758	10,538	4,502	49	—	3
1918	112,339	1,020	9,787	9,858	54	15	2
1919	44,801	1,221	3,534	2,105	55	291	23
1920	10,665	1,430	7,190	4,401	71	480	20
1921	8,995	1,305	2,241	4,576	57	129	5
1922	21,493	1,382	5,691	6,370	40	339	27
1923	8,461	993	5,316	4,162	52	531	7
1924	18,935	838	4,834	3,933	59	1,407	13

**Tuberculosis.**—In answer to Colonel Day, Mr. Neville Chamberlain said the gross expenditure on tuberculosis treatment by local authorities of England and Wales in 1922-23 was £348,718 capital expenditure and £2,749,073 other expenditure. For 1923-24 the capital expenditure was not known, but the other expenditure was £2,766,131. Answering Colonel Heneage, Mr. Chamberlain regretted that the number of persons in Great Britain suffering from tuberculosis in 1924 was not available. He had issued special regulations which would provide reliable data next year of the number of tuberculous persons whose cases had at any time been notified and who were still suffering from the disease at the end of 1925. In England and Wales in 1924, 41,103 persons died from tuberculosis. In England and Wales 72 persons under 15 years of age died from tuberculosis of the glands and bones. He could not say in how many of these cases milk infection was traced. The Medical Research Council's investigations indicated that in 20 per cent. of cases of bone and joint tuberculosis in children which were investigated the infection was of bovine origin. In cases of gland tuberculosis the percentage was considerably higher.

**Pensions.**—Captain Gee asked the Minister of Pensions whether awards made by medical boards were subject to revision by officials of the Pensions Department. Major Tryon said every award made under the Royal Warrant was in accordance with an assessment by a medical board which had seen and examined the man. The assessment could be referred to a board, but in every case a board which had seen the man made the final assessment. The officials had no power to alter assessments, but the assessors could point out that in their opinion the medical board had assessed a man too high or too low. In reply to a further question by Captain Gee, Major Tryon said that for years there had been arrangements with local institutions whereby the Ministry obtained electro-cardiograms when they were considered medically necessary. As medical examination was carried out at centres throughout the kingdom it was impracticable to provide an instrument at the Ministry. Captain Gee asked whether, through the absence of an electro-cardiograph at the Pensions Department, many ex-service men failed to establish their claim for cardiac disability, though, in private hospitals which possessed an electro-cardiograph, they were found to suffer from heart trouble. Major Tryon repeated that the Ministry found it best to use instruments which were locally

available. In reply to questions by other members, the Minister of Pensions said: (1) That he saw no ground for setting up a special committee of medical and other advisers on hardships occurring through the time limit on appeals against final awards where a man's condition had become materially worse or a second or third disability had arisen. (2) That so long as the clinic at Broad Street, Holborn, was in operation, and the Ministry of Pensions had cases which could usefully be sent to it, the department would continue to use it. The clinic belonged to the British Red Cross Society, and the question of closing it was not a matter for the Ministry. (3) That the records of the Ministry of Pensions did not show how many widows, children, or dependants of dead ex-service men were receiving pensions when the cause of death was general paralysis of the insane.

**Maternity.**—Mr. Groves asked the Minister of Health to urge local authorities to arrange, where the prospective mother was too poor to engage the services of a qualified medical man, that this service should be provided freely. Mr. Chamberlain said that under the Midwives Acts the services of a doctor were available in emergencies without cost to the patient if she was unable by reason of poverty to pay the doctor's fee. The circular of June 30th, 1924, also urged the provision of maternity beds, and in individual cases local authorities were recommended to make good any deficiencies in this respect discovered on inspections by the medical officers of the Ministry of Health. Sir Kingsley Wood said that on May 1st the number of maternity and child welfare centres in operation in England and Wales was 2,368.

**Poisoning by Hydrochloric Acid.**—Colonel Day asked the Minister of Health the number of deaths caused by drinking spirits of salts during 1924. Mr. Chamberlain said the figure for 1924 was not available. In 1923 the deaths from hydrochloric acid poisoning were 73 suicidal and 7 accidental. These figures did not differ appreciably from those of the two previous years. On the information available there did not seem any ground for increasing the restrictions on the sale of hydrochloric acid, which were already imposed by the Poisons and Pharmacy Act, 1908.

**Hospitals.**—The Minister of Health hopes to receive the report of the Voluntary Hospitals Commission before the end of June; 963 approved societies with a membership of about 5,000,000 persons include payments to hospitals or convalescent homes in their existing schemes of additional benefit. About £210,000 was spent on this additional benefit during 1924, the greater part being paid in respect of the treatment of members in hospitals.

**Silicosis.**—The Home Secretary informed Mr. J. Hudson that the Home Office was investigating the incidence of silicosis in the potteries industry. An inquiry into silicosis in the stone industry would be taken in hand next. These inquiries were necessary before a scheme could be framed under the Workmen's Compensation (Silicosis) Acts, 1916 and 1924. Silicosis could not suitably be scheduled under the Workmen's Compensation Act. He was aware of the occurrence of silicosis among men working certain kinds of stone.

#### Notes in Brief.

The number of accidents resulting in death or personal injury caused by vehicles in Great Britain during 1924 was: Fatal, 3,631; non-fatal, 94,584; total, 98,215. Of the fatal accidents, 3,019, and of the non-fatal, 64,318 were due to mechanically propelled vehicles other than trams and trackless trolley vehicles. In London, during 1924, there were 59,122 street accidents in which motor vehicles were concerned.

The Home Secretary hopes to introduce the Coroners Bill very shortly.

Government expenditure for scientific research in 1925-26 is estimated to exceed £4,000,000.

The Minister of Health is not aware that chrysamine is used by hawkers to colour unripe oranges, but his attention has been called to a case where chrysoidine was used. There is no evidence of toxicity which would justify prohibition of the use of these colouring matters.

## Correspondence.

### WIDAL'S HAEMOCLASIC CRISIS TEST FOR LIVER FUNCTION.

SIR,—As I was working in Professor Widal's clinic in Paris during the winter of 1923-24, and had, therefore, opportunities for seeing the French technique of this test at its source and for discussing the results with the originators of the method, I may perhaps be excused for making a few comments on Dr. A. F. Bernard Shaw's article in the BRITISH MEDICAL JOURNAL of May 16th (p. 914).

The haemoclastic crisis was discovered many years before any attempt was made to apply it as a test for liver function. In investigating anaphylaxis in its various clinical manifestations it was established that certain phenomena occurred with, or just preceded, the onset of the anaphylactic symptoms. The most important of these phenomena were: a fall in the leucocyte count and in the arterial blood

pressure, an increase of the clotting time of the blood, and a lowering of the refractive index of the blood serum. The presence of this haemoclastic "shock", or "crisis" was demonstrated in such varying conditions as oedema, asthma, and paroxysmal

has propounded an hypothesis, which is admittedly purely speculative, to explain the phenomena of haemoclastic. He suggests that the colloidal constituents of the body fluids are normally in a condition of equilibrium. In a sensitized individual minute quantities of an incompatible colloid (or even, it is claimed, of a crystalloid) may disturb this equilibrium to a more or less profound degree. This "colloidal crisis" is accompanied by those changes in the blood described as the haemoclastic crisis. Haemoclastic, therefore, is, according to this hypothesis, an indication of some disturbance of "colloidal equilibrium" in the body fluids—a disturbance which becomes clinically evident by the appearance of the symptoms of the various diseases and conditions which are generally recognized as being due to anaphylaxis or "protein shock."

The test for liver function arose out of the foregoing theory. It was argued that an impaired liver would be likely to let imperfectly metabolized protein products pass into the systemic circulation, that these would be likely to produce a mild colloidal crisis, and that this latter could be recognized by the appearance of a haemoclastic crisis. This argument was confirmed by animal experiments. In animals with an Eck's fistula a protein meal produced a haemoclastic crisis, and a similar result was obtained by injecting portal blood from an animal digesting a protein meal into a healthy animal. For the purposes of a clinical test it was therefore proposed to give a fasting subject a protein meal and to watch for the occurrence of a haemoclastic crisis. Furthermore, Widal suggested that for clinical purposes the leucocyte count and arterial blood pressure, being the simplest investigations to perform, would be sufficient to reveal the presence or absence of a haemoclastic crisis.

Dr. Bernard Shaw's main criticism of the test is that there is a normal and physiological variation in the leucocyte count which vitiates the results however careful the technique. In this he is supported by other recent writers, and I think there can be little doubt that the criticism is sound. But this does not necessarily mean that the test is useless. It is peculiarly unfortunate that Widal should have selected as the criteria of a haemoclastic crisis two things which appear to be profoundly influenced by outside factors. Both the leucocyte count and the blood pressure seem to vary from moment to moment in healthy subjects, and there is evidence to show that both may be affected by psychic and emotional disturbances. But we are not, I think, justified in denying that a haemoclastic crisis follows a protein meal in a subject with an impaired liver until the refractive index and the coagulability of the blood have been investigated. Neither of these investigations is very complicated to perform, and it would seem, on the face of it, that they might provide a more reliable indication of the occurrence of a haemoclastic crisis. At any rate, I do not think that Dr. Bernard Shaw is justified in stating that the test "lacks a theoretical basis." Its basis, if anything, suffers from being too theoretical.—I am, etc.,

London, S.W.1, May 24th.

MAURICE E. SHAW.

### SLEEP AND SLEEPLESSNESS.

SIR,—In Dr. C. P. Symonds's interesting paper on this subject in the JOURNAL of May 9th (p. 869), I note that there is no reference to the use of high-frequency currents as an important method of combating sleeplessness. So far back as 1905 I read a paper in London, before the Electro-Therapeutic Society on the benefit obtained in cases of pure insomnia, when pain was not the cause, through the use of high-frequency currents. At the same time I gave notes of the results of this form of treatment.

Drugs, of course, can produce sleep, but they are all more or less poisonous, and the sleep produced by them is not as a rule refreshing. On the other hand, the sleep which follows the application of high-frequency currents is dreamless and childlike; on waking the patient has none of the unpleasant sensations so often caused by the use of drugs, but is refreshed both in mind and body. I have employed

these currents for almost a quarter of a century, and can therefore speak of their value with the utmost confidence. Never have I seen any deleterious results, and the failures have been scarcely worth mentioning.

The method employed has been the condenser couch, 250-800 milliamperes being passed through the patient daily. Sometimes high-frequency massage, principally over the skin of the back, was employed, the patient holding an electrode connected with one of the poles, whilst the operator, in direct connexion with the other terminal, completed the circuit by laying his hand on the patient's skin.

It is a common occurrence for patients undergoing high-frequency treatment for some other complaint—for example, neuritis—to offer the unsolicited remark that they are now sleeping much better, and that as a consequence the lethargy and listlessness previously complained of have disappeared.

To the May number (1906) of *Medical Electricity and Radiology* I contributed a paper, illustrated by charts, showing how the surface temperature of the body was raised, even as much as  $17^{\circ}$  F., by passage of high-frequency currents. With this rise on the surface of the body it is reasonable to conclude that a certain amount of cerebral anaemia occurs, and this may well account for the sleep produced. As a rule also pulse rate and the blood pressure are reduced. Whatever be the explanation, the fact remains that insomnia may be safely, confidently, and successfully treated by the use of high-frequency currents, and this is true of severe as well as of slight cases.—I am, etc.,

Glasgow, May 19th.

W. F. SOMERVILLE, M.D.

#### RELAPSE IN MEASLES.

SIR,—Sir John W. Moore's interesting and informative letter in the *Journal* of May 16th (p. 946), in reply to the question, Is there such a thing as relapse in measles? prompts me to relate the following: On April 8th last I was called to see a little girl of 5 with all the signs of measles; temperature  $103^{\circ}$ . The next day the rash was unmistakable and the conjunctivitis severe. There was also much cough and bronchitic signs in the chest. At the end of eight days the child was apparently quite well, except that there was still some swelling of the eyelids.

On the twelfth day I was summoned again, the mother stating that the child's eyes were much worse. The temperature was now  $102^{\circ}$  and the eye symptoms much more severe. There was also sneezing, recrudescence of the cough, and, to my surprise, a copious rash, which the next day was again absolutely typical of measles. The second attack ran almost as severe a course as the first, but the child is now recovering, although much debilitated.

At no time was there any resemblance to either German measles or scarlet fever.

As a matter of interest, I might add that I have seen two or three cases of measles in children under 3 months during this last epidemic.—I am, etc.,

Llanelli, May 19th.

OSCAR WILLIAMS, M.B., B.S.Lond.

#### CLEAN MILK.

SIR,—I think that Dr. Chalmers Watson is mistaken in imagining that Scottish local authorities are unaware of the value of graded milk, or that Paisley is a pioneer in the matter.

The Anderson Sanatorium for Tuberculosis at Hawick has been supplied with Grade A tuberculin-tested milk since last August, and the South-Eastern Counties Joint Sanatorium at East Fortune, under my friend Dr. Cameron, has been similarly supplied for a considerable time. The East Fortune institution serves the counties of Midlothian, Peebles, West Lothian, East Lothian, Roxburgh, Selkirk, and Berwickshire. It may be worth stating that the Burgh of Hawick (about 16,000 inhabitants) has two sources of supply, and that there are four in this county, with a fifth about to start. One dairy company draws its supply from without the county—namely, from Cumberland. The tuberculosis authority of the county of Roxburgh is keenly interested in the matter of clean milk, and draws attention to milk dangers in its domiciliary pamphlet.

While writing of milk, I would like to add that milk is not necessarily clean because it is distributed in bottles. The

public should know that graded milk and milk in bottles are not always the same thing. Experience has led me to believe that this point is not appreciated by everyone.—I am, etc.,

Newtown St. Boswells, May 23rd.

G. B. PAGE, M.D.

#### INDIVIDUAL MEDICAL DEFENCE.

SIR,—Dr. Henry Robinson states (May 9th, p. 804) that in my letter (May 2nd, p. 861) I glozed over the issue of "the overwhelming importance of a large reserve fund to a medical defence society," and then reiterates that the present societies have large reserves, while the proposed British Medical Association society will have none. Why does he harp so much on one string? The chorus in which he is joined by Dr. Tracy Lydall will get rather monotonous.

It is obvious that a reserve fund is important to an insurance society, especially if it is to carry the whole of its liabilities. But in these days of re-insurance reserve funds are of less importance, especially to a medical defence society, than a sure steady premium adequate to meet the risks. Dr. Robinson's society insures with the Yorkshire Insurance Company: a wise course, and I cannot understand why he wishes me to "withdraw unreservedly" the paragraph in my letter of May 2nd dealing with this relationship. I am willing to do so if he will point out where I am in error. I have no wish to create a wrong impression, and, to avoid this, perhaps I should explain that some years ago the Medical Defence Union issued separate policies of the Yorkshire Insurance Company to its members. For each of these policies a premium of 7s. 6d. was charged, and the insured was covered, subject to the conditions of the Union, up to £2,000. Now these separate policies have been discarded and the Union pays a lump sum to the company. In 1922 it paid £1,280 3s. 9d. for 9,375 members, which works out at 2s. 9d. a member. These figures are taken from the balance sheet of the Union. Since the Harnett case the Medical Defence Union and the London and Counties Medical Protection Society have given unlimited cover without increase of subscription. This does not mean that their reserve funds have increased to an unlimited extent; it means that the premium for re-insurance has been increased proportionately to meet the increased liability; or it may even mean that, owing to increased membership, the premium per capita is not increased, although there is increase in the total sum. As regards the new company, I have every confidence that the Council of the Association will be able to work out a sound scheme of finance, and if it should require a guarantee fund for a short period to allow the company to get established, an appeal from it would not go unanswered.

I come now to the much more difficult question of the relationship of a defence society to serious professional misconduct involving the honour of the profession, and only indirectly affecting the public. I must thank Dr. Robinson for so promptly answering my question whether his society would prosecute one of its own members before the General Medical Council for a grave professional offence. Dr. Gillbard thinks this a naive query, but why should he assert that it settles the case against the Association taking up medical defence, when an experienced manager like Dr. Robinson states that such action would be *ultra vires*? In illustration of the difficulty, allow me to quote an instance.

In 1923 a defence society, at the instance of Dr. X, one of its members, prosecuted Dr. Y, a member of another society, before the General Medical Council for alleged advertising and canvassing. This was quite a legitimate case of one defence society against another. But what would the position have been had Dr. X and Dr. Y both been members of the same society? (I suppose it was merely a matter of chance that they were not). In such a case, according to Dr. Robinson, Dr. X could not have gone forward with his charge through the defence society against Dr. Y. He would have had to do it privately at his own expense, and Dr. Y would have been defended by the society of which Dr. X was also a member. It seems a curious position.

When the question of indirect advertising came into prominence the General Medical Council was very loth to issue a Warning Notice (which it eventually did) without a case being brought before it. Of course, no one would

undertake, nor was there any organization willing to undertake, the heavy expense and worry of bringing a case to the seat of judgement.

All this goes to show that the organization of the profession is very incomplete, and those who think that the proposed Association company would be at a disadvantage with regard to G.M.C. cases as compared with the existing defence societies should realize that these societies are equally tied in respect of their own members. The proposed society will have one advantage that the other societies lack, and that is the help of the ethical machinery of the Association for adjudication of professional differences. Those interested in this topic will find in Section V of the Association's *Handbook* a lucid and comprehensive statement on medical ethics, and they will appreciate how naturally and logically the objects and rules of the proposed society will fit in and follow para. 128 in future issues of the *Handbook*. Dr. Bolam has done much to improve medical organization by co-operation with the Society of Medical Officers of Health, and I trust that with the capable assistance of Dr. Morton Mackenzie (whom I must thank for the information in his letter published on May 9th), he will be able to make another advance after the Representative Meeting at Bath.—I am, etc.,

Warrington, May 10th.

J. S. MANSON.

### Medico-Legal.

#### REX v. BATEMAN.

##### CONSIDERED JUDGEMENT OF COURT OF CRIMINAL APPEAL.

In the Court of Criminal Appeal, on May 25th, the Lord Chief Justice of England (Lord Hewart) delivered the considered judgement in the appeal of Dr. Percy Bateman of New Cross Road, London, against his conviction and sentence at the Central Criminal Court for manslaughter. The appeal was heard on February 9th, and the proceedings on the previous application for leave to appeal and on the appeal itself were fully reported in the *BRITISH MEDICAL JOURNAL*, February 7th (p. 285) and February 14th (p. 334). It will be remembered that the appeal was allowed and the conviction quashed, but the Lord Chief Justice, in announcing this decision, stated that in view of the importance of some, at any rate, of the questions raised the court proposed to consider its judgement and deliver it on a later date.

At the delivery of the considered judgement the Lord Chief Justice was accompanied by Mr. Justice Salter; Mr. Justice Fraser, who also heard the appeal, was absent.

##### The Facts of the Case.

The Lord Chief Justice began by summarizing the facts of the case. The appellant, Percy Bateman, was convicted at the Central Criminal Court, before Mr. Justice Shearman, for manslaughter, and was sentenced to six months' imprisonment in the second division. He appealed, by leave, against that conviction and sentence. The court, after hearing arguments of counsel, quashed the conviction and intimated that a considered judgement would be delivered at a later date.

The appellant, who was a qualified medical practitioner, was indicted for having, on July 30th, 1924, unlawfully killed one Mary Ann Harding, whom he had attended in childbirth. He was called in by the midwife to attend the woman on July 23rd, and found an unusual and difficult presentation. He administered chloroform and attempted, unsuccessfully, to effect delivery by instruments. No blame was imputed to him on that account. He then proceeded, by using his hands, to perform the operation known as version, employing, of necessity, considerable force. He worked at this operation for an hour, and then delivered the child dead. By mistake he removed, along with the placenta, a portion of the uterus. The patient was much exhausted, and the appellant did not expect her to live. He visited her twice daily until the 28th. Although requested by her husband and the midwife to have her removed to the infirmary, he did not have her so removed until the 28th. On admission to the infirmary she was found unfit to undergo an operation, and she grew gradually weaker and died on the 30th. At the *post-mortem* examination the bladder was found ruptured, the colon was crushed against the sacral promontory, there was a small rupture of the rectum, and the uterus was almost entirely gone.

The charges of negligence made against the appellant were in substance three: (1) causing the internal ruptures on performing the operation of version; (2) removing part of the uterus along with the placenta; (3) delay in sending the patient to the infirmary. For the defence it was contended that (1) and (2), in the difficult circumstances of the case, were not inconsistent with a fair degree of care and competence, and as regards (3), that he had removed the patient at an earlier date would have accelerated her death. At the hearing of the appeal counsel for the appellant urged misdirection on law, misdirection and non-direction on the facts, and that the verdict was against the weight

##### The State of the Law.

Before dealing with the directions of the learned judge to the jury it was desirable to consider generally the state of the law on this subject. In expounding the law to juries, judges had often referred to the distinction between civil and criminal liability. The law of criminal liability was conveniently explained in that way. If A had caused the death of B by alleged negligence, then, in order to establish civil liability, the plaintiff must prove, in addition to the pecuniary loss, that A owed a duty to B to take care, that that duty was not discharged, and that such default caused the death of B. To convict A of manslaughter it was necessary, in addition to these three things, to satisfy the jury that A's negligence amounted to a crime. In a civil action, if it was proved that A fell short of the standard of reasonable care, the extent of the liability depended, not on the degree of negligence, but on the amount of the damage done. In the criminal court, on the contrary, the amount and degree of negligence were material questions. The difference between "negligence" and "gross negligence" was illustrated by the case of *Cashill v. Wright* (as reported in *Ellis and Blackburn*, vol. 6). This was an action against an innkeeper by a traveller for the loss of certain goods stolen from him while putting up at the inn. The defendant contended that the loss had been occasioned or contributed to by the negligence of the plaintiff. At the trial the jury were directed that the defence failed unless they thought the plaintiff had been guilty of gross negligence, and the verdict was for the plaintiff. The case was carried to appeal before Lord Chief Justice Campbell, Mr. Justice Woodman, Mr. Justice Erle, and Mr. Justice Crompton, and Mr. Justice Erle (as he then was), in delivering the judgement of the Court, said:

"The other question was as to the alleged misdirection in the direction to the jury that there must be gross negligence, to maintain the defence. It does not appear that there was any information given to the jury as to what they were to understand by gross negligence. If they were told to understand by gross negligence the absence of that ordinary care which, under the circumstances, the prudent man ought to have taken, as seems to have been the meaning given to gross negligence in some of the modern cases cited before us, the direction as to the degree of negligence might not have been objectionable; but the legal meaning of gross negligence is greater negligence than the absence of such ordinary care. It is such a degree of negligence as excludes the lowest degree of care and is said to amount to *dolus*."

The rule was made absolute.<sup>2</sup>

The Lord Chief Justice continued:

In the directions to juries on the test to apply in order to determine whether or not negligence amounted to a crime judges have used many epithets, such as "culpable," "criminal," "gross," "wicked," "clear," "complete." But whatever epithet is used, and whether an epithet is used or not, to establish criminal liability the facts must be such that, in the opinion of the jury, the negligence of the prisoner goes beyond a mere matter of compensation between subjects, and shows such disregard for the life and safety of others as to amount to a crime against the State and conduct deserving of punishment. It remains to consider the application of this principle to cases like the present in which there is alleged negligence on the part of a person possessing special knowledge and skill against whom a charge of manslaughter is preferred.

##### The Possession of Special Knowledge and Skill.

The Lord Chief Justice here mentioned the titles and references in the legal case-books of some eighteen cases which, he said, illustrated this point. They included several of the cases mentioned in the arguments during the hearing of the appeal. He continued:

The law as laid down in these cases may be thus summarized. If a person holds himself out as possessing special skill and knowledge, and he is consulted as possessing such skill and knowledge by or on behalf of a patient, he owes a duty to his patient to use due caution in undertaking the treatment. If he accepts the responsibility and undertakes the treatment, the patient submits to his direction and owes a duty to the patient to use skill, and caution in administering the treatment. The relationship is necessary, nor is it necessary that the service shall be rendered for reward. It is for the judge to direct the jury what standard to apply, and for the jury to say whether that standard has been reached. The jury should not exact the highest or a very high standard, nor should they be content with a very low standard. The law requires a fair and reasonable standard of care and competence. This standard must be reached in all the matters above mentioned. If the patient's death occurs it will not avail for the defendant to show that he had sufficient knowledge, nor that he was diligent in attendance, if the patient was killed by his unskillfulness and carelessness. As regards cases where incompetence is alleged, it is only necessary to say that there an unqualified practitioner cannot claim to be measured by any lower standard than that which is applied to the qualified man. As regards cases of recklessness juries are likely to distinguish between the qualified and the unqualified man. There may be recklessness in undertaking the treatment and recklessness in the conduct of it. It is conceivable that a qualified man may be held liable for undertaking a case which he knew or should have known was beyond his powers. In the case of a quack, where the treatment has been proved to have been incompetent, and to have caused the patient's death, juries are not likely to hesitate in finding liability on the ground that the defendant undertook and continued to treat his case involving the gravest

<sup>1</sup> "Dolus" in civil law means malicious or criminal intent.

<sup>2</sup> This case of *Cashill v. Wright* was decided in 1856.

risk to his patient when he knew he was not competent to deal with it.

The foregoing observations deal with civil liability. To support an indictment for manslaughter the prosecution must prove all the matters necessary to establish civil liability (except pecuniary loss) and, in addition, must satisfy the jury that the negligence and incompetence went beyond a mere matter of compensation between subjects, and showed such disregard for the life and safety of the patient as to amount to a crime against the State and conduct deserving of punishment.

#### *The Summing up of Mr. Justice Shearman.*

The Lord Chief Justice next addressed himself to the summing up of Mr. Justice Shearman at the Central Criminal Court, and read several lengthy passages. At the outset of the summing up the learned judge had said:

"The law is that anybody who causes the death of anybody else—it does not only apply to a doctor, it applies to motor drivers, railwaymen, or signalmen, it applies to a number of people—anybody causing the death of anybody else is criminally responsible. It is equally clear law that no one is criminally responsible for what I call making a mere mistake, and it is really for the jury to draw the line between what is called making a mere mistake, an error of judgement, and doing something which is grossly and palpably wrong. I have only one objection to make to the law as put before you by the counsel for the defence: that a man is bound to do [?] act to the best of such skill as he has. That is not quite accurate. A medical man who practises for profit the medical profession professes skill: he does not come and say, 'I am an unskilled person'—he is engaged and professes skill. Of course, you will understand it is not for every humble man of the profession to have all that great skill of the great men in Harley Street; but on the other hand, they are not allowed to practise medicine in this country unless they have acquired a certain amount of skill: they are bound to show a reasonable amount of skill according to the circumstances of the case, and you have to judge them on the basis that they are skilled men, but not necessarily so skilled as more skillful men in the profession, and you can only convict them criminally if in your judgement they fall below the standard of skill which is the least qualification which any doctor should have. You should only convict a doctor of causing a death by negligence if you think he did something which no reasonably skilled doctor should have done."

The learned judge had continued:

"You have got to consider if this man in anything he did fell below the level which you expect of a doctor—below that degree of skill which you think you have a right to expect of a doctor—by no means the extreme skill which everybody knows of, but that degree of skill which you expect from a doctor who attends an accouchement and who is taken to know his business."

In the course of his review of the evidence the learned judge referred to the law in the following passages:

"It is said that this man so treated her that by his treatment he committed all these injuries: he ruptured the womb, he ruptured her bladder in pushing about, and he caused the injuries to her intestines; and in the same way it is said that when he came to pull out the placenta, instead of pulling the placenta out of the womb he caught hold, not of the placenta, but of some tear or slit in the torn womb, and with a tug—the expression was a 'sharp pull'—he pulled it away. It is said by the Crown that that shows that in doing this, and in pulling out the womb, he was guilty of gross negligence. It is said on behalf of the defence—and they called eminent surgeons—'Well, the nurse saw nothing wrong with the way he treated her, although the force was used, and was necessary, and it was unfortunate.' It is said that there was no gross negligence, and it is for you, if you feel any doubt, to see that the prisoner gets the benefit of the doubt, but are you satisfied on that that there was gross negligence? The doctors called for the defence say this: they say, 'Oh, it is quite reasonable to mistake a tear in the womb for the placenta.' That is entirely a matter for you, and it is a view not entirely accepted by the doctors called for the prosecution, although they agree in cross-examination that after all this working a portion of the womb might be torn, but a reasonably skilful man might note the difference between pulling the womb and something that might be adherent to the inside, and the prosecution call attention to the fact of the steady outflow of the blood, and say that in pulling out the womb he was guilty of gross negligence, and the defence was, a very natural mistake, in the circumstances of the case."

Again, to continue the quotation:

"The Crown first of all say there was gross negligence, and you will not find it unless you are quite satisfied of it, in pulling away the womb at all—in what he did before and in pulling it away. It is suggested by the defence, nothing of the sort; at most and at worst it was a mistake, and we say it was not negligence; it was the sort of thing that might happen in this remarkable case."

And again:

"Passing away from that and summing up the first case, if you think and are satisfied that it was his treatment in tearing away the womb—previous to and up to tearing away the womb—you will convict him; if you are not satisfied and think there was no negligence at all, or if you have a reasonable doubt whether there was gross and culpable negligence, up to that point you will acquit him."

Again:

"That, substantially, is the case for the Crown on the second part of the case, and they say substantially he was guilty of grave, wicked negligence and culpable neglect of duty in not taking some steps to remedy what had been done by his own fault; or if you do not think it was gross negligence they say he ought to have done something to try and save this woman's life, but he did not do anything because he wished to save his own reputation."

Again:

"Those are the historical facts. Do you think, assuming you are satisfied by the prosecution that in pulling away the womb at all and the acts preceding, that he was guilty of gross negligence and culpable negligence in causing her death?"

"Then you come to the second head. Was he guilty of gross or culpable negligence in accelerating this woman's death by so neglecting her from the time that he knew her uterus had been removed? If you are quite satisfied that the woman wanted treat-

ment and, from the history of the case, that if she had had some treatment her life would have been prolonged, you will find him guilty; if you have any doubt about it you will find him not guilty. I would remind you of what I said to you at the outset that you have to be satisfied, not only that he was guilty of gross and culpable negligence, but that he caused or accelerated her death. . . . That is the whole case. If you are satisfied that either in the way he delivered the child or in the way he acted afterwards he acted with gross negligence and thereby caused her death, you will find him guilty; if you are not satisfied you must acquit him on that part of the case. If you think that after the womb had come away his conduct and neglect of her substantially accelerated the date of her death—if you are satisfied of that, you will convict him on that part of the case. If you feel any reasonable doubt on either theory you will give him the benefit of the doubt and acquit him."

The Lord Chief Justice went on:

"So far the passages from the summing up. If the words 'gross,' 'wicked,' and 'culpable' are put aside, this summing up amounts to a direction to the jury that they must draw the line between mistake or error of judgement on the one hand and carelessness and incompetence on the other. If there was only mistake or error of judgement there was no liability, but if there was anything short of the average degree of care and competence then there was liability. Such a direction would be complete and adequate on a trial of an action for damages; it was not adequate for trial for manslaughter. There is a frequent use of the adjectives which have always been used in these cases, and for this reason this court as a whole is of opinion that there was no misdirection. It is, nevertheless, most desirable that in trials for manslaughter by negligence it should be pressed on the jury that the issue is, not negligence or no negligence, but felony or no felony. It is desirable that as far as possible the explanation of criminal negligence to a jury should not be a mere question of epithets. It is in a sense a question of degree, and it is for the jury to consider the degree; there is a difference in amount between the negligence which gives a right to compensation and the negligence which constitutes a crime."

The learned judge was invited to withdraw the first and second charges from the jury. He declined to do so. The learned judge left all three charges to the jury. The jury returned a general verdict of "Guilty." In the opinion of this court there was no evidence to support the first charge (that based on the manner in which the accused performed the operation of version). A strong defence was presented on the third charge, and it might well be that the jury relied largely on the first and second charges. If the first charge had been withdrawn from them it is impossible to say they would certainly have convicted. For this reason the conviction could not stand.

#### THE "E.R.A." CULT.

##### NEW ZEALAND PRACTITIONER STRUCK OFF THE REGISTER.

On the motion of the New Zealand Medical Board, the name of Henry Dundas Mackenzie, medical practitioner of Auckland, was ordered by Mr. Justice Herdman, sitting in the Supreme Court of New Zealand, on March 30th, 1925, to be removed from the *Medical Register of New Zealand*, two years being fixed as the time after which he may apply for re-registration. The hearing of the action lasted nine days.

Dr. Mackenzie is a graduate of the Homeopathic Medical College, Missouri, U.S.A.—not now existing—and commenced practice in New Zealand in 1896. In 1920 he spent a few months in the clinic of Abrams at San Francisco, studying electronic reactions alleged to be obtained by the use of the Abrams box, and upon his return to Auckland with a diagnostic outfit, and an oscilloclast, or treatment machine, set up as a specialist in cancer, the words "Cancer and chronic diseases" being inscribed upon his door-plate. On August 16th, 1924, Mrs. Lawrence, of Hamilton, New Zealand, was awarded £2,000 damages against Dr. Mackenzie for negligence in the diagnosis and treatment of a cancerous growth of the breast.

On the motion for the removal of Dr. Mackenzie's name from the *Medical Register*, the New Zealand Medical Board alleged that he had been guilty of infamous conduct in a professional respect in practising the Abrams method of diagnosis and treatment in such a manner as to show that he could not honestly have believed it was a reliable or useful method in the cases in which he employed it.

#### *Judgement of the Supreme Court.*

Mr. Justice Herdman, in his judgment, admitted that he held himself out as a medical practitioner in this title. It was well justified this title. It was well there was a substantial percentage of error with the Abrams machine might be from 50 to 60 per cent. Evidence called went to prove that in certain instances, at any rate, Dr. Mackenzie relied for his diagnosis upon the Abrams machine alone, and never attempted to get corroboration of his finding by employing common clinical diagnosis methods. The contention of the Medical Board was that his actions and his methods proved that he had no honest belief in the Abrams system or the apparatus, and that he used it not so much for the purpose of discovering and treating disease as for the purpose of enriching himself. It was difficult to understand why in one case Dr. Mackenzie, possessing as he did expert knowledge which

enabled him to find the ulcer, and knowing that two other practitioners had diagnosed cancer, should not have attempted to consult the other men, or get some independent opinion, before accepting the final responsibility of finding a verdict against cancer. Time was of supreme importance in such a case as this. Every day that passed lessened the patient's chances of living. Unfortunately, in this instance (the judge continued) the Abrams machine in the hands of Dr. Mackenzie failed to detect a cancer which, in the opinion of other practitioners, was discoverable with ease.

In another case Dr. Mackenzie had announced after a machine test that the patient had cancer, whereas upon the evidence it seemed plain that the lady had not, and never had, cancer, and that there was no shadow of justification for suddenly making the startling announcement that she was the victim of a deadly disease. There was no evidence of any kind that Dr. Mackenzie endeavoured to fortify the opinion that he had formed from the machine by any clinical examination or by suggesting that any other opinion should be obtained. If he (the judge) accepted the patient's statement, then Dr. Mackenzie deliberately terrified the woman and strove to keep her out of the hands of legitimate practitioners. In the judge's opinion the inference that Dr. Mackenzie's conduct throughout that case indicated that he had any honest belief in the merits of the Abrams machine could not reasonably be drawn. The boggy of cancer had been raised in so many of the cases investigated during the hearing of that motion, and raised without any justification, and the advantages of Dr. Mackenzie's special treatment were so consistently stated, that one was forced to conclude that it was all done deliberately, and with a purpose, the purpose being to keep patients away from the practitioner who practised the sciences of medicine and surgery in accordance with principles that were generally recognized as being sound, and to force them into accepting treatment which brought substantial remuneration to the practitioner who raised the cry "cancer." Dr. Mackenzie's definitions of the disease he described as "carcinosis" were a medley of contradictory and unsatisfactory statements, altered as the circumstances of the case changed, whilst his rough announcement to a woman who was afterwards successfully operated upon for fibroid tumour, that she had cancer, was conduct which could not be described in language of moderation. It was with regret that he found himself driven to infer from the facts proved that with Dr. Mackenzie the Abrams system was only a means to an end. It was a means used primarily, not for the purpose of discovering disease and treating disease, but it was a means by which credulous people were attracted to the surgery where false hopes were raised and money easily gained. The judge referred to the refusal of Dr. Mackenzie to allow an impartial test of the system of diagnosis from blood, or from handwriting. If Dr. Mackenzie wished the truth told, why did he burke an investigation? The personnel of the proposed committee could not be objected to. It was ridiculous to suggest that any one of the gentlemen proposed to make the test would be guilty of dishonesty and fraud. As to the witnesses produced by the defence, to his mind there was no conclusive and convincing proof that cure or improvement spoken to by them was traceable to the Abrams method. The trial of the system was refused, and he could only conclude that those who refused such trial had no confidence in it. If there existed this lack of confidence—and it did exist—then this fact went a long way to prove that Dr. Mackenzie in his own mind must have doubted the soundness of the system. It seemed to him that one inference only could possibly be drawn from the accumulation of fact and circumstance before him—that Dr. Mackenzie had no honest belief in the usefulness and reliability of the system that he practised.

If a practitioner, in the practice of his profession, adopted and used a system in which he had no belief, then he accepted reward for services rendered by him which he must believe to be of no value. If he led the public to believe that the system in which he had no faith could detect disease and could be used to check or cure disease, then he was not acting honestly and in good faith, and he brought himself within the words of the statute and was guilty of "infamous conduct in a professional respect." It was not enough for Dr. Mackenzie to say that he believed in the system. That bare statement standing alone would not justify him when the facts were against him, when those upon whom the onus rested had shown that his acts and conduct had set at defiance the principles of professional honour and credit. In these proceedings that onus had been discharged, and Mr. Justice Herdman found himself obliged to come to the conclusion that the charge against Dr. Mackenzie had been proved.

Notice of appeal has been lodged.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

At a congregation held on May 23rd the degree of doctor of medicine (D.M.) was conferred on H. E. A. Boldero.

### UNIVERSITY OF LONDON.

Dr. E. C. Dodds has been appointed to the University Chair of Biochemistry tenable at Middlesex Hospital Medical School. The title of Emeritus Professor of Bacteriology in the University has been conferred upon Professor R. T. Hewlett as from August 1st, 1925, on his retirement from the University Chair of Bacteriology, and public health in the closing of the department of bacteriology. The degree of D.Sc. in Physiology has been conferred upon Mr. B. Babkin, an internal student of University College.

Dr. R. A. Young has been appointed to represent the University at the annual conference of the National Association for the Prevention of Tuberculosis to be held in London in July next.

Sir Holburt Waring will represent the University at the Imperial Social Hygiene Congress to be held at the British Empire Exhibition at Wembley in October next.

The semi-general election of members of the Senate for 1925-29 has resulted in the appointment of the following representatives by the bodies indicated:

Dr. B. Graham Little, M.P.; Royal London, Sir Wilmot Herringham, K.C.; City and Guilds of London Institute, Dr. G. Newton Pitt; Faculty of Medicine, Sir Holburt Waring.

### LONDON HOSPITAL MEDICAL COLLEGE.

The prize distribution at the London Hospital Medical College will take place on Tuesday next, June 2nd, at 3 p.m., when Dr. Charles H. Mayo of Rochester, U.S.A., will present the certificates.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

At a meeting of the College held on May 20th, Sir Harold J. Stiles (President) in the chair, the following twenty-four successful candidates, out of fifty-five entered, who had passed the requisite examinations, were admitted Fellows:

Robert Findlay Allan, Captain Billeddra Dasa, I.M.S., Edward Jocelyn Billeffe, James Wares Brobauer, Russell Exon Butchart, Edwin Clark, Harold Keith Corkill, Daniel de Bruyn, John Alexander Docton, Francis Henry Edward

Dr. Sidney Scott Sumner, Theobald, John Maurice

The Bathgate Memorial Prize, consisting of bronze medal, set of books, and instruments, was, after a competitive examination in materia medica, awarded to Sydney Whyte Cruickshank, and the Ivison Macadam Memorial Prize in chemistry, consisting of bronze medal and set of books, was awarded, after competitive examination, to Frank Kerr Fenton.

### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SENORARY.—F. T. Birkinshaw, M. R. Burke, T. G. L. Davies, N. H. Ibrahim, J. H. Clapp, J. Herbert, J. H. Rutherford, B. Temple-Raston, I. Waynik, M. E. G. Wilkinson, F. T. Birkinshaw, F. T. Birkinshaw, J. H. Clapp, D. T. Jenkins, I. H. Mackay, J. Maingard, C. J. Rozario, J. Shutt, B. Temple-Raston, M. R. Burke, F. T. Birkinshaw, A. F. Brigmea, D. T. Jenkins, E. W. D. Long, M. E. G. Wilkinson.

The diploma of the Society has been granted to Messrs. M. R. Burke, T. G. L. Davies, D. T. Jenkins, J. Maingard, O. W. Percival, R. J. Rutherford, and B. Temple-Raston.

## Obituary.

### THE MALARIA COMMISSION IN PALESTINE.

A TERRIBLE accident befell the members of the League of Nations Malaria Commission in Palestine. A party of five were returning from Beit Meri, a summer resort ten miles from Beyrout, when their car overturned and three members were killed—Major N. V. C. Lothian, R.A.M.C.(ret.), Dr. Samuel Darling, a representative of the Pan-American Health Committee of Washington, and Mlle Besson. Mme Delmas, wife of the chief medical officer of the French Army of the Levant, was seriously injured. Dr. Schwellegrebel, a Dutch representative, and the driver, a Frenchman, were slightly injured.

Major Lothian was nearly 38 years of age, having been born on July 31st, 1887. He was educated at Glasgow University, where he graduated M.A. and B.Sc. in 1909 and M.B. and Ch.B. in 1912. He took the D.P.H. and D.T.M. at Cambridge in 1919, and also held the certificate of the Medico-Psychological Association. After graduation he filled the posts of house-physician of the Glasgow Western Infirmary, house-surgeon of the Glasgow Royal Infirmary, and medical officer of the Stirling District Asylum at Larbert. He took a commission as lieutenant in the Special Reserve of the R.A.M.C. on May 8th, 1913, and transferred to the regular army in the same rank in January, 1914. He became captain in the great war promotion list of March 30th, 1915, and was given a brevet majority in June, 1919; he retired in April, 1923. He served during the war in charge of a divisional sanitary section, and for three years as a D.A.D.M.S. in the Near East, mainly on epidemiological work. He was mentioned in dispatches in the *London Gazette* of January 1st, 1916, December 6th, 1916, and November 28th, 1917, received the Military Cross on January 1st, 1918, and was also awarded the French Croix de Guerre.

## Medical News.

ON May 25th, at the Royal Society of Medicine, Sir William Collins presented the Chadwick gold medal and prize to Wing-Commander Whittingham, R.A.F. Professor Emilio Brumpt, of the Paris Faculty of Medicine, delivered a Chadwick public lecture on the conduct of an antimalarial campaign, illustrating his remarks with more than a hundred epidiascopes illustrating to demonstrate the breeding places of mosquitos in all parts of the world, and various researches into the life-history of the parasite and preventive measures. Professor Brumpt's next lecture will be on May 29th, at 5.15 p.m., in the lecture hall of the Royal Society of Arts, on the prophylaxis of sleeping sickness. Further particulars of the Chadwick lectures may be obtained from the secretary at the offices of the Chadwick Trust, 13, Great George Street, Westminster.

THE next meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine will be held at Cambridge on June 20th in the biochemical laboratory. At 2.30 p.m. a paper will be read by Dr. Kay and Dr. Vines on bone formation and experimental rickets. After tea Dr. J. F. Gaskell will contribute a paper on the relation of experimental pneumonia in rabbits to the pneumonias of childhood. The members will dine together at 7 p.m.

THE annual prize-giving at St. Thomas's Hospital Medical School will take place on Tuesday, June 23rd, at 3 p.m., in the Governors' Hall. The prizes will be distributed by H.R.H. the Duke of Connaught, and tea and music will be provided on the terrace.

THE Fellowship of Medicine announces that the first of the new series of lectures will be given on June 9th, when Sir Thomas Horder will speak on "Some cases of fever without physical signs." The lectures are to be delivered at No. 1, Wimpole Street, at 5.30 p.m. A four weeks' course (from June 2nd to 27th) in venereal diseases will be given at the London Lock Hospital (Dean Street), and a course in dermatology at St. John's Hospital for Diseases of the Skin. From June 3rd to 25th, eight clinical demonstrations on the more important diseases of tropical countries will be given at the London School of Hygiene and Tropical Medicine, by Dr. Low and Dr. Maunson-Bahr. The Chelsea Hospital for Women will hold a course from June 8th to 27th; the Victoria Park Hospital a two weeks' course in diseases of the heart and lungs, from June 8th to 20th; and St. Peter's Hospital a course in urology from June 15th to July 11th. An intensive course in medicine, surgery, and the special departments has been arranged by the London Temperance Hospital from June 22nd to July 4th. Copies of the syllabus for the above courses may be obtained from the Secretary to the Fellowship of Medicine, No. 1, Wimpole Street, W.1.

THE Council of Epsom College is about to select candidates for a Gerald Stanley Medical Scholarship, which is open to the necessitous son of a medical man. Candidates must be fully 12 years of age, and be intended for the medical profession. The scholarship is of the value of about £130 a year, and is payable in advance to the Bursar of Epsom College. It will not be continued beyond the scholar's 17th birthday, by which time he should have passed the matriculation examination of the University of London, or its equivalent. On joining a medical school the holder of the scholarship will be required to attach himself to that of St. Bartholomew's Hospital, where, under certain conditions, a further scholarship will await him. Full particulars and forms of application can be obtained from the secretary at the office of Epsom College, 49, Bedford Square, W.C.1.

AN International Industrial Welfare Congress will be held in Flushing from June 20th to 26th. By this means it is hoped that a permanent link will be established between the countries through the formation of an international association for the study and promotion of satisfactory human relations in industry. An interim committee has drawn up a draft constitution for presentation at the Congress. Those wishing to attend are requested to send their names to the Secretariat, c/o Miss M. L. Fledderus, Glassworks, Leerdam, Holland.

DURING the recent German elections six medical practitioners, including one woman, Dr. Moses of Berlin, were elected to the Reichstag.

A CHAIR of epidemiology is to be established at the Collège de France, with Professor H. Vincent as its first occupant.

INVITATIONS have been issued to visit the National Physical Laboratory at Teddington on the afternoon of Tuesday, June 23rd.

THE annual meeting of the French Association for the Advancement of Science will be held at Grenoble from July 17th to August 9th.

THE sixteenth Italian Congress of Hydrology, Climatology, and Physical Therapy will be held at Montecatini, under the presidency of Professor G. D. Quelrolo, from July 11th to 14th. The principal subject for discussion will be the hydrological treatment of cholera-biasis. Further information can be obtained from the general secretary, Professor Carreras, Clinica Medica, Pisa.

IT is proposed to erect a monument to the late Professor Guido Baati in the University of Florence. Subscriptions should be sent to the rector of the University, Professor G. Chiarugi.

THERE are 57 lepers in Finland, mostly suffering from the maculo-anæsthetic form of the disease. They are all natives of the south-western part of the country, and the majority are being treated in the State sanatorium for lepers at Orivesi. In Sweden there were 37 lepers in 1923.

THE Institute for the Study of Tuberculosis and the Effects of High Altitudes at Davos has arranged to hold a climatological congress there next August (17th to 22nd). Particulars can be obtained from the secretary, Dr. Vogel-Eysen, Davos-Dorf, Switzerland.

ACCORDING to the *Journal of the American Medical Association*, only five of the sixty-nine cities in the United States with a population of more than 100,000 had a diphtheria mortality rate greater than 20 in 1924, as contrasted with 17 in the preceding four years' average, and thirty-seven had rates less than 10, as contrasted with 16 in 1920-23. Fourteen cities had rates under 5, while none averaged so low in 1920-23.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Those who wish notice to be taken of their communications should sign them with their names, not pseudonyms.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2.

THE TELEPHONE NUMBER of the **BRITISH MEDICAL JOURNAL** is **MUSEUM 9864**. The telephone number of the **British Medical Association** remains, until further notice, **Gerrard 2630** (internal exchange).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London*.

FINANCIAL, SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London*.

MEDICAL SECRETARY, *Mediscera Westrand, London*.

The address of the Irish Office of the **British Medical Association** is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin); and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

DR. R. M. RUSSELL (Forest Gate) writes in reply to "X" (May 9th, p. 908): With reference to the patient whose nerves are upset by thunderstorms, it would be well if he could live where thunderstorms are rare. I lived in the North of Ireland for four years and during that time there were no thunderstorms. Donaghadee is the place most free from rain there. I have read that St. Leonards-on-Sea is fairly free from thunderstorms.

## RELIEF OF PAIN IN BURNS AND SCALDS.

DR. E. E. LLEWELLYN (Ramsey, Hunts) writes to express a doubt whether a remedy for burns and scalds which must be a hundred years or more old has been superseded for common use. Some ordinary whitening is mixed with fresh milk and spread on lint. It gives immediate relief in superficial lesions, and children stop crying soon after its application.

## SLOW HEART.

DR. D. A. DIAS (Preston) writes: Dr. Rickard W. Lloyd may like to hear of another case of slow heart. The pulse rate of a woman, aged 75, at present under my care with uræmia, was for two days 24; on one occasion the pulse and apex beat were 24 and the respirations 26 a minute. The blood pressure was (systolic) 210 mm. She improved and was removed to more comfortable quarters; her pulse is now 33 a minute, counted at different intervals of the day.

**VACANCIES.**  
NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39.  
A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 24.

## An Address

ON

## INFUNDIBULIN:

THE INDICATIONS FOR ITS USE IN SURGICAL  
AND OBSTETRICAL PRACTICE.\*

BY

W. BLAIR BELL, B.S., M.D. LOND.,

PROFESSOR OF GYNAECOLOGY AND OBSTETRICS IN THE UNIVERSITY OF  
LIVERPOOL; GYNAECOLOGICAL AND OBSTETRICAL SURGEON,  
ROYAL INFIRMARY, LIVERPOOL.

I WAS much pleased to receive an invitation to address this society on the active principle of the posterior lobe of the pituitary body, for it is now sixteen years since I was responsible for the introduction into clinical practice of this preparation, to which I gave the name "infundibulin."<sup>1</sup> Almost immediately it came into general use throughout the civilized world. Watson, then professor of obstetrics in the University of Toronto, writing in 1913, said:

"It seldom happens that a new drug or remedy comes into universal use in such a short space of time as has been the case with pituitary extract in obstetrical practice. Since it was first used . . . in 1909 it has been employed in practically every obstetrical clinic throughout this continent and in Britain and Europe."<sup>2</sup>

In these circumstances we may assume that the interval of sixteen years which has elapsed since infundibulin was first employed has been long enough to enable us, not only correctly to appraise the value of this remedial agent in clinical practice, but also to establish the indications for, and contraindications to, its use. During this period the practical applications have been so considerably extended that I was not surprised to be asked to confirm or refute the prevalent belief that the potent properties of this extract are frequently, and quite unconsciously, abused in obstetrical difficulties. I shall deal with this important matter in due course, and shall endeavour to be as definite as possible in the opinions expressed, for it may be that some guidance on the matter is desired by the conscientious practitioner in view of the very general employment of infundibulin, and, possibly, the inaccessibility of the literature in which the chief indications and contraindications have been specifically stated.

## HISTORICAL.

The observation by Oliver and Schafer<sup>3</sup> in 1885 that an extract of the whole pituitary had a pressor effect upon the blood pressure for some time escaped further recognition and investigation, being overshadowed by the coincidental statement of these investigators that the extract made from the suprarenals was more powerful in this respect. In 1898 Howell<sup>4</sup> demonstrated the fact that it is the extract of the pars posterior (pars intermedia and pars nervosa) alone that has a pressor action; that prepared from the pars anterior has no such characteristic. Subsequently to 1898 occasional papers appeared in physiological journals dealing for the most part with the action of infundibulin on the cardio-vascular and renal systems.

During the years 1907 and 1908 Hick and I<sup>5</sup> conducted a series of experiments, an account of which was published early in 1909. Later in the same year the clinical paper, to which reference has already been made, was published. From 1910 onwards there was a deluge of Continental communications on the subject, but practically no new ground was broken. To-day infundibulin is an established agent for the relief of many serious conditions; but before we consider these a brief survey of our physiological knowledge concerning the substance itself may not be out of place.

## THE ORIGIN, NATURE, AND DESTINATION OF INFUNDIBULIN.

It will be remembered that all the epithelial elements of the pituitary arise from the ectodermal cells of that upward prolongation of the angle made by the roof of the stomodeum and the pharyngeal membrane, which has come

to be known as Rathke's pouch. The hollow neural process of the diencephalon—the infundibulum—descends to meet this pouch, and is closely applied to the epithelium without the intervention of connective tissue.

The original cavity of Rathke's pouch forms the cleft of the pituitary body, and from the anterior side gland-like diverticula are developed. In this way the pars anterior is formed. The cells on the posterior aspect of the pouch, adjacent and adherent to the pars nervosa, or infundibulum, constitute the pars intermedia. The cells of the pars intermedia have therefore the same origin as those of the pars anterior. This is important; and it is probable that the secretion of the cells of the pars intermedia, like that of the cells of the pars anterior, has no pressor action. The pars posterior, as we have seen, consists of the pars intermedia and pars nervosa; and since separation at the cleft is a simple matter the whole posterior lobe is used as the material from which infundibulin is extracted commercially.

Nevertheless, one of the most interesting problems connected with infundibulin is its origin and destination. Several observers<sup>6, 7</sup> have stated that it is possible in the laboratory more or less completely to separate the pars intermedia from the pars nervosa, and that an extract made from the nervous portion gives all the typical reactions of infundibulin, whereas one made from the cells of the pars intermedia is comparatively inert. Other observers<sup>8</sup> have obtained exactly contrary results; but most investigators have confirmed the work of Osborne and Vincent. This subject and the inherent difficulties surrounding the complete separation of the two parts are discussed in my work on the pituitary.<sup>9</sup>

It may, however, be accepted that although the pars intermedia has a definite secretion of its own, which is sometimes granular, sometimes colloid, and about which we know very little, yet, on the other hand, some of the adjacent cells of the pars intermedia and their secretion pass into the pars nervosa—which is structurally composed of neuroglial cells and fibres—and there undergo alteration: the nuclei disappear from the cells, the cytoplasm forms a mass of granular substance, resembling the aggregations of granular secretion formed from the cells in the pars intermedia, and infundibulin is produced.

According to Herring<sup>10</sup> and others, the pars intermedia cells and the granular secretion pass through the pars nervosa to the central cavity, if there be one,<sup>11</sup> but in any case reach the third ventricle. I have never been able, on the evidence adduced, to satisfy myself of this as an inevitable or even usual sequence. The fact that pressor substances have been found in the cerebro-spinal fluid is not conclusive. My own view is that the secretion from the pars intermedia which passes into the pars nervosa is altered there; and normally is taken up as fully formed infundibulin by the numerous thin-walled vessels present in the pars nervosa. The chemical nature of infundibulin has not been established.

## Pressor Action of Infundibulin.

Infundibulin has a most characteristic pressor action on all involuntary muscle, including the heart muscle; moreover, it affects the involuntary muscle fibres that may be scattered through such organs as the spleen and mammary glands. The effects with which we are immediately concerned are those produced on the cardio-vascular system, the alimentary tract, the uterus, and the bladder. A feature common to all is that the result obtained is more pronounced when there is atony of the muscle. Further, it is an interesting fact that the pressor action of infundibulin is maintained for a longer period of time than is the case with suprarenalin.

## METHODS OF ADMINISTRATION.

The mode of administration of any drug or extract is a matter of considerable moment, yet it is surprising how thoughtless many are in regard to this matter. The method of election is based on a knowledge of certain fundamental particulars; for example, it is useless to give suprarenalin by the mouth, for it is destroyed by the gastric juices; on

\* The central cavity of the infundibulum persists in some mammals—for example, the cat—but is completely obliterated in many, including the primates.

\* Delivered to the Northern Counties Medical Society, Newcastle-on-Tyne.

the other hand, we believe that those digestive secretions have no destructive action on infundibulin. Nevertheless, in surgical and obstetrical conditions in which an immediate pressor effect is required it would be absurd to administer pituitary extract by the mouth, although such a procedure may be useful in the treatment of metabolic disorders coming under the care of a physician.

Again, how frequently is the practice adopted of administering infundibulin hypodermically, in spite of the fact that it has been demonstrated repeatedly that the effect obtained by this method is much slower and much less pronounced than that which follows intramuscular and intravenous injections. It is probable that all the unsatisfactory results that have been reported in regard to the pressor action of infundibulin have been due to a wrong method of introduction, generally hypodermic, and to the use of badly prepared products. The former source of dissatisfaction is easily remedied in surgical and obstetrical work: the extract must always be given intramuscularly or intravenously. I find the triceps the most convenient muscle for the purpose.

#### *Standardization of Infundibulin.*

In respect of the efficiency of the preparations used therapeutically we are entirely in the hands of the manufacturing chemists, some of whom, no doubt, may shelter themselves behind the recognized difficulties of exact standardization of organic extracts of unknown composition. Still, it is certain that some preparations are comparatively inert, and others more active than the average. The liquid extract, as usually prepared, is stated to be of a strength of 20 per cent.—that is to say, 0.2 gram of fresh pars posterior is extracted with 1 c.cm. of saline solution. The albuminous matter is removed, and the preparation is sterilized by filtration through unglazed porcelain.

In the past the method usually adopted for standardization, if so it can be called, has been the reaction to the preparation of infundibulin of a strip of uterine muscle from one of the lower animals. As there are generic and seasonal variations in the reactivity of this muscle, the results obtained are not likely to be delicate or conclusive.

The chromatophore reaction in amphibia, described by Hogben and Winton in a series of papers, is hardly likely to prove more than an extremely sensitive qualitative indication of the presence of infundibulin, if, indeed, it prove to be a specific reaction. A quantitative method of standardization is required, and this cannot readily be obtained until we know the chemical formula of infundibulin. Accurate dosage will then be a simple matter.

It appears possible that some persons are more susceptible to the action of infundibulin than others; yet it is difficult to estimate such an idiosyncrasy, which may be nothing more than a local expression of the degree of the involuntary muscle paresis for which the preparation has been administered.

I propose here to confine my attention entirely to the use of infundibulin in surgical and obstetrical practice, and to say nothing of the many conditions in which its properties have been utilized by the gynaecologist and physician.

#### GENERAL CONTRAINDICATIONS TO THE USE OF INFUNDIBULIN.

Infundibulin should not be administered during an operation if there be respiratory failure, for the normal amplitude of respiratory movements is diminished by the extract.

When there is myocardial or valvular disease of the heart without complete compensation infundibulin is absolutely contraindicated. A fatal issue may follow the exhibition of a small dose. Even in the presence of compensation it is a dangerous drug to employ.

In renal disease associated with a high blood pressure the use of infundibulin is inadvisable.

The special contraindications which apply to the stimulation of intestinal and uterine muscle will be specified in the appropriate places.

#### INDICATIONS FOR AND CONTRAINDICATIONS TO THE USE OF INFUNDIBULIN IN SURGICAL PRACTICE.

##### *The Prevention and Treatment of Shock.*

Shock, as is well known, may be caused by trauma and loss of blood, alone or together; by toxæmias, bacterial and chemical; and by violent psychical disturbances. It is generally agreed that in this state the systolic blood pressure is reduced—that is, there is loss of tone in the unstriated muscle tissue. As indicated, the production of a low blood pressure by one of the causes mentioned, although insufficient, perhaps, to produce a definite degree of shock, may, when associated with another of the causes, also acting in a minor degree, lead to the establishment of this state by a summation of effects.

Now, in the prevention of shock much can be done by the use of infundibulin in debilitated patients with low blood pressure. The administration of this extract several times each day for several days before a serious operation, undertaken in septic or cachectic cases, often enables the patient to withstand the traumatic effects of operation and the toxæmic effects of the anaesthetic.

Many surgeons at the present time adopt the precaution during an operation of any magnitude of having the blood pressure recorded every few minutes. For a number of years my anaesthetist has made a routine practice of this procedure, and I am sure he would bear me out when I say that it has often given him warning that the patient's condition is deteriorating many minutes before any other evidence was available. In such circumstances an injection of infundibulin may save the situation.

In a city so near the Scottish border I am perhaps on dangerous ground when I say that chloroform is not only more hæmolytic, and more conducive to acidosis, than ether, but also has a more immediate and serious effect on the blood pressure. Infundibulin will do much to mitigate the last, but intelligent co-operation to simplify the work demanded of it is not to be despised. So, too, in regard to shock associated with loss of blood: it is clear that to raise the tone of muscle in empty vessels is a futile procedure, but that the maintenance of tone after the transfusion of blood or other colloid preparation is of the utmost importance. As stated, infundibulin raises the tone of hypotonic unstriated muscle to a far greater degree than is the case when the tone is normal.

Infundibulin, then, is of inestimable value in the treatment of shock, provided it is used with an intelligent appreciation of the nature of the condition, and of the factors concerned in the production of it.

##### *The Prevention and Treatment of Post-operative Gastric and Intestinal Atony.*

Few surgeons have not been faced with the problem of intestinal atony following abdominal operations. So common has been this complication that in some clinics the routine injection of infundibulin at stated intervals after operation is practised, in order to prevent ileus supervening. I do not think this should be necessary in "clean" cases; but much depends on the way in which the intestines and peritoneum are protected from injury and are treated during the operation. It will be generally agreed that to-day the technique of intra-abdominal interference in such patients has reduced the appearance of this distressing complication almost to vanishing point.

In septic cases, and in those in which there has been a certain amount of trauma in the separation of adhesions, which should be divided with sharp scissors or a knife whenever possible, paralytic distension is not infrequently encountered; and in them the preventive use of infundibulin, by means of intramuscular injections of 0.5 c.cm. every few hours, should form a regular part of the after-treatment of the patient. Should distension be already present when the matter is taken in hand, it is advisable that, ten minutes after an intramuscular injection of infundibulin, which sensitizes the intestinal musculature, a turpentine enema should be given slowly by means of a catheter and funnel.

In order to obtain a certain pressor effect on the intestinal muscle it is essential that a large dose be administered—namely, 1 c.cm. This dose followed by a turpentine enema

often gives a dramatic result. Similarly, in the rare condition of acute dilatation of the stomach, this organ should be washed out ten minutes after infundibulin has been injected.

The use of infundibulin in these complications is contra-indicated if an operation involving repair or anastomosis of the stomach or intestines has been performed, and, of course, if unrelieved obstruction be present.

#### Vesical Atony.

When there is atony of the musculature of the bladder with distension in pressor effect and evacuation may follow an injection of infundibulin, but this result is somewhat uncertain.

After some gynaecological operations, and after parturition, it is not unusual for a patient to be unable to evacuate the bladder unaided. With good nursing and a proper use of the catheter it is rare for any protracted disability to occur. If, however, the patient be not carefully watched, there is always the possibility of an "overflow bladder"—paralytic distension, with overflow.

The inability voluntarily to empty the bladder can generally be overcome by the judicious use of infundibulin and a catheter. The bladder is allowed to become full to the normal extent, an injection of 1 c.cm. of the liquid extract is then given, and ten minutes later a small catheter is passed. When the flow commences the catheter is withdrawn, and in many cases micturition will continue naturally. Although this by no means always happens, and it may be necessary to repeat the procedure a number of times, I think it should be tried, for the long-continued invalidism that may follow vesical paresis cannot be lightly regarded.

#### INDICATIONS FOR AND CONTRAINDICATIONS TO THE USE OF INFUNDIBULIN IN OBSTETRICAL PRACTICE.

I do not propose to discuss the stimulation of uterine contractions in relation to abortion beyond saying that pituitary extract is not an abortifacient in the presence of a live foetus. When that period of gestation at which the foetus is viable has been reached, this extract becomes a most potent agent which may be used to the advantage or disadvantage of the patient.

#### Induction of Labour.

So far as the use of infundibulin is concerned for the termination of pregnancy, the indications may be classified as follows:

- (a) For the expulsion of a dead child.
- (b) In order to obviate the possibility of disproportion between the maternal and foetal parts.
- (c) In the treatment of ante-partum haemorrhage.

In the first and second groups there is usually no urgency, and induction can be planned to suit the circumstances of the case. Infundibulin administered every four hours for several days in doses represented by 0.5 c.cm. of the liquid extract occasionally precipitates labour; but such an event is comparatively rare unless the patient be at term or the child is dead.

In those cases in which the dates and examination of the uterus and foetus reveal full-term pregnancy, and in which there is a strong probability of post-maturity, it is a very wise procedure to administer the extract as indicated. Labour in these circumstances often follows. If it does not, and in all ordinary cases in which induction at the thirty-sixth or thirty-seventh week is desired, the administration of infundibulin four or more times in each twenty-four hours for three days should be followed by the insertion of bougies, and after this the injections should be continued if labour does not supervene before the next dose is due. The uterus has been rendered so sensitive by the extract that the mechanical irritation of the bougies is greatly enhanced, and labour usually supervenes within a few hours.<sup>11</sup>

In the treatment of ante-partum haemorrhage infundibulin plays an important role. It is recognized by all obstetricians that the first method of treatment in cases of accidental haemorrhage in which the bleeding is not entirely

concealed, and in which there are indications for interference, consists of rupture of the membranes and an intramuscular injection of infundibulin. Whether the foetus be at full term or premature does not matter, provided there are no general contra-indications to the use of infundibulin. With regard to accidental haemorrhage which is entirely concealed, infundibulin should not be employed until the uterus has been emptied. Even then the response will depend on the state of the uterine musculature.

In placenta praevia, especially when the implantation is not central, infundibulin may form a valuable adjunct to other methods of treatment, such as rupture of the membranes. There is no specific danger whatsoever in the judicious use of infundibulin before labour has started, for, although subsequently labour pains may be strong, in my experience there has never been any evidence of excessive expulsive force.

#### Caesarean Section.

The question now naturally arises as to the use of infundibulin after Caesarean section. In ordinary cases an injection of 0.5 c.cm. of the liquid extract should be made into the triceps of the patient *after the uterine wound has been sutured*, if retraction appears then to be incomplete. When an injection is given before the uterus has been sutured, especially if it be given into the uterine muscle, it may be almost impossible properly to approximate the incised muscle wall of the uterus.

When, however, Caesarean section has been performed for concealed accidental haemorrhage and the uterus has been preserved, infundibulin should be injected directly into that organ. In these circumstances numerous injections of a few cubic millimetres should be made in various parts of the uterine wall. As already indicated, the result will, however, depend in a great measure on the damage sustained by the muscle bundles, among which scattered effusions of blood are often found.

#### Uterine Inertia.

A glance through standard textbooks is sufficient to indicate how limited has been the study, and consequently how incomplete is our knowledge, of uterine inertia. Some authors show an inclination to consider "primary" and "secondary" inertia as dissimilar phenomena, and not, as they really are, similar phenomena relative to time and space.

Until such time as the whole question has been made clear by the closer consideration of the chemical stimuli and reflex inhibitions involved, and in order to avoid complicating matters, it may be advisable to adhere to the classification universally adopted and to consider uterine inertia under the usual headings.

#### "Primary" Uterine Inertia.

"Primary uterine inertia" is the term applied to uterine inertia occurring before the second stage of labour. In order properly to explain the most useful role played by infundibulin in primary uterine inertia of a pathological type, it is important that I should make a few remarks on primary inertia in general.

Primary uterine inertia is of two kinds—physiological and pathological.

*Physiological primary uterine inertia* is a merciful and advantageous natural phenomenon. I believe it to be of a reflex and inhibitional character—that is to say, owing to some unusual and generally more or less obstructive condition, such as occipito-posterior presentation in a primigravida, for a long time the uterine contractions are feeble. I would, indeed, go further, and say that the inherent factor responsible for the weak pains of the normal first stage, especially in the primigravida, is the relatively obstructive condition of the incompletely dilated cervix. It is not, in fact, the weak contractions that are responsible for the slow dilatation of the os, but rather it is that the undilated os reflexly inhibits the uterine contractions. This may, by those who do not follow my reasoning closely, be regarded as splitting straws, but it is not so in reality, as that which follows will demonstrate.

In the first place, the blood pressure may be high. Secondly, if an injection of infundibulin be given in such

circumstances, this is not always followed by an increase in the expulsive contractions, although the tone of the uterine muscle is raised; but once the cervix is fully dilated, or almost fully dilated, the contractions may become in these circumstances dangerously violent. Nevertheless, in primary uterine inertia of the physiological type, although Nature will do her best to thwart our evil designs, we should never administer infundibulin, for it is not required, and, unless the diagnosis be accurate, serious trouble may follow.

*Pathological primary uterine inertia*, as is well known, may be due to inherent pathological conditions of the uterine musculature caused by multiparity, overdistension of the uterus from various causes, fibromyomata, and the rest; but with these I am not at the moment concerned. I refer rather to that form of primary uterine inertia which is associated with a normal uterine musculature; I mean the inertia that is due to an insufficiency of pressor substances in the blood. It is commonly believed that in these circumstances the output of infundibulin is insufficient.

This is a subject in which I have been much interested since I first drew attention to the importance of the diagnosis and treatment.<sup>1</sup> A bad obstetrical history of patients, who have quite evidently suffered with primary uterine inertia in previous labours, is frequently forthcoming, and I have seen more than one patient on whom Caesarean section has been performed for this condition. It is, however, most important that it should be recognized, if present, as it often is, during the first pregnancy, for not infrequently primary uterine inertia due to the cause under consideration dogs a woman throughout her obstetrical career.

*Pathological primary uterine inertia* of this type is diagnosed before labour commences, and should therefore be excluded, or its presence proved, in every pregnant woman during the last two weeks of gestation. When the patient is examined at this period, in normal circumstances palpation of the uterus through the abdominal wall and traction on the nipples excite painless but very definite contractions; during the period of relaxation the tone of the uterus is found to be good. If now the systolic blood pressure be recorded, it will be found to be above the average for non-pregnant normal women of the same age as that of the patient. When labour is due the blood pressure is often considerably raised.

On the other hand, in women in whom there is impending uterine inertia, it will be observed either that it is impossible to elicit uterine contractions at all, or that, when aroused, they are feeble and fleeting. Moreover, in quiescence the uterus feels flabby and atonic on abdominal palpation. The systolic blood pressure in these circumstances is found to be reduced to the equivalent of 110 mm. of mercury, or even less. I have therefore treated cases of primary pathological inertia of this type with infundibulin whenever the condition has been recognized and checked by a blood pressure reading—a method of corroboration that is always essential. The success of this treatment has been most encouraging. I regret that time will not allow me to record in detail some of the cases I have had under my care.

In such circumstances 0.5 c.cm. of the liquid extract is administered intramuscularly two or three times every day, according to the interval before labour is due. When a patient has been treated in this way before the onset of labour, it is usually quite unnecessary to administer any more of the extract during subsequent parturition, for the pains are then strong and forcible. If, however, the uterine contractions should become weak, there is no reason why infundibulin should not again be employed, provided the patient is multiparous and there are no contraindications, general or local.

In those other, not uncommon, instances to which reference has been made, of pathological primary inertia due to local anomalies, rather than to insufficiency of pressor substances in the blood, we are concerned with an abnormal condition of the muscular tissue due to various causes. I do not propose to consider the rarer of these; it will be enough to refer only to the effects produced by multiparity, and by overstretching of the muscle fibres by hydramnios

and multiple pregnancy. In such circumstances the muscle does not respond to stimuli so forcibly as the normal tissue; consequently stimulation must be greater. In the absence of contraindications, and although the blood pressure be normal, the fluid extract may therefore be administered in small doses under careful observation, after labour has started.

#### "Secondary" Uterine Inertia.

"Secondary uterine inertia" is the term employed to denote an absence, or diminution in the efficiency, during labour of the uterine contractions, which previously had been normal. Secondary inertia may be due to the same causes as those responsible for primary inertia.

It is clear that in those cases in which the musculature is abnormal owing to multiparity, and other causes the inertia is primary in origin, although possibly the contractions may have been strong enough to carry labour unaided through the first stage. It is unnecessary further to consider the treatment in such cases.

Strictly speaking, as I have indicated in my definition, the term "secondary inertia" implies a temporary failure of the uterine muscle to continue contracting normally. Now, it is usually stated that this is due to exhaustion of the uterine muscle. Can we be satisfied with this explanation, which, after all, had its origin in the distant past? I do not think there are inherent structural quantitative differences in the musculature of the uterus in different women of the same age, such as may be seen, for instance, in the skeletal muscles. Any differences that obtain are the result of local lesions, to which I have referred, or to constitutional conditions, which no doubt also influence the availability of pressor substances.

I believe that the usual form of secondary inertia is that which supervenes during a protracted labour: gradually the uterine contractions diminish in frequency and force as the result of exhaustion of the pressor substance in the blood. The condition is probably not due to exhaustion of muscle fibres in the uterus, for with muscle fatigue further stimulation creates no response, whereas in these cases a response is always obtainable by means of infundibulin. Confirmatory evidence of this view is found in the lowered blood pressure associated with secondary uterine inertia. In the presence of a sufficiency of pressor substances, if the labour be obstructed, an irritable condition of the muscle supervenes, and this may terminate in tonic contraction, especially when mechanical stimulation, in the form of operative interference, is superadded.

I have gone at some length into this matter because it is the realization of these points that makes it possible for us to state definitely the indication for the use of infundibulin during labour, and to emphasize the serious contraindications the neglect of which has led to many grave disasters. Before infundibulin is given during labour the accoucheur must have informed himself quite clearly that the contraindications to the use of this preparation are absent, and that the indication for it is beyond reasonable doubt.

#### Indication for the Use of Infundibulin during Labour.

The only scientific indication for the use of infundibulin during labour is the evidence, readily obtainable, of insufficiency of this substance in the blood. This evidence consists of a history of protracted labour, during which the previously normal contractions gradually diminished in force and frequency, and the state of the blood pressure. I have nothing to say against the practice of administering soporifics and of allowing the patient to recuperate. In many cases this is advisable. During the period of rest the pressor substances reaccumulate in the blood, and labour may terminate naturally. When, however, the head is low in the pelvis, and the pains cease for a long period of time, then, all else being equal, the best interests of the patient and child are served by the administration of infundibulin. So, too, when there has been inertia throughout the whole course of labour, this disability may be successfully treated by occasional injections of infundibular extract.

The question of dosage is of some moment. It is advisable during labour never to administer as an initial dose a greater quantity than 0.25 c.cm. intramuscularly. In a majority of

cases it will be found that this dose is quite effectual. It may, however, safely be repeated after an interval of two hours. If this small dose appears to have but little effect, then 0.5 c.cm. may be injected on the next occasion, but this quantity should not be exceeded.

#### Contraindications to the Use of Infundibulin during Labour.

The contraindications to the use of infundibulin extract during labour are very clearly defined. In the first place, any disproportion between the foetal and maternal parts absolutely prohibits the exhibition of this preparation. Even though there be inertia due to prolonged labour, and a low blood pressure, indicating the exhaustion of pressor substances from the blood, infundibulin should not be given. To do so in the presence of recognizable disproportion is to run the grave risk of rupture of the uterus.

With respect to the statement made concerning arrest of the head when low in the pelvis, the frequency of such an occurrence due to contraction of the pelvic outlet must be remembered, otherwise a disaster may follow the use of infundibulin. The fact, too, that there is always relative disproportion in primigravidae, owing to the rigidity of the soft parts, must be borne in mind, and grave consideration must always be given to the question of employing infundibulin, which may lead to precipitate delivery with extensive lacerations of the maternal tissues, if not to rupture of the uterus.

Secondly, the presence of efficient uterine contractions is an absolute contraindication to the employment of infundibulin, for if in these circumstances no progress is made, obstruction, relative or absolute, exists.

It will be evident, then, that infundibulin must be used with extreme caution during labour. The scientific indication must be established, and the contraindications excluded with certainty. Moreover, it is a very sound rule that when forceps are indicated infundibulin is contraindicated, and this in spite of the invitation to us, published in press advertisements, to leave forceps at home and try somebody's specially potent brand of extract.

I have heard of so many cases in which the uterus has been ruptured as the result of the injudicious use of infundibulin—cases of this kind are rarely published—that sometimes I feel inclined to revert to the declaration made in my first paper, that infundibulin should not be used during labour. Yet to do so would be wrong; properly used, infundibulin, with its power of producing regular, rhythmic, and forcible uterine contractions in the absence of a sufficiency of pressor substances, and when the uterine musculature is deficient, may be a most valuable and beneficent agent in the hands of a careful accoucheur.

There is no one, I take it, who seriously doubts that the general use of infundibulin to terminate labour is as culpable as the indiscriminate application of forceps for the same time-saving purpose.

#### Third Stage of Labour.

The routine use of infundibulin as soon as the second stage of labour is over, to promote expulsion of the placenta, and to hasten the third stage, has been advocated.<sup>12</sup> I do not, however, regard such a procedure as either scientific or expedient when the labour up to this point has been normal, especially when there has been no inertia. If the placenta has been retained in these circumstances it is generally adherent, and the administration of infundibulin may cause the uterus to contract down upon it, rendering subsequent removal difficult. I have seen such cases myself, and I believe that this is what has happened in those instances that have been recorded of so-called hour-glass contraction of the uterus after delivery of the child. If, however, there has been inertia, or a long anaesthesia with the abolition of efficient contractions of the uterus, it is often wise to give infundibulin after the birth of the child, if it has not been given as an aid to delivery.

Infundibulin may be most advantageously employed after expulsion of the placenta, when uterine inertia has permitted post-partum haemorrhage. In these circumstances it is advisable to follow the intramuscular injection of 0.5 c.cm., or the intravenous injection of 0.25 c.cm. of the liquid extract in a little saline, by an intramuscular injection

of ergotin, the efficacy of which is increased by the previous administration of infundibulin.

#### Subinvolution of the Uterus.

During the puerperium and in the subsequent weeks subinvolution of the uterus may be effectually treated by the administration of infundibulin. It is obvious that the sooner intramuscular injections are given, once the condition has been recognized, the better will be the result.

In conclusion, I would urge that infundibulin must always be employed with care, and with a due regard to the scientific indications in every case. The greatest harm and the gravest disasters have occurred in obstetrical practice from the injudicious use of this potent substance during labour.

## THE TREATMENT OF CONGENITAL CLUB-FOOT.

BY

B. WHITCHURCH HOWELL, F.R.C.S.,

SURGEON, QUEEN'S HOSPITAL FOR CHILDREN, LONDON; SURGEON TO BROOKFIELD ORTHOPAEDIC HOSPITAL; LATE ORTHOPAEDIC SURGEON TO THE MINISTRY OF PENSIONS.

The treatment of congenital club-foot must commence from the moment of birth, when the structures in the foot are soft and pliable, and little pain or shock is experienced by the infant.

There are four principal varieties of congenital club-foot: talipes equino-varus, equino-valgus, calcaneo-valgus, and calcaneo-varus; a less common deformity which sometimes requires treatment is mid-tarsal varus.

The principles of treatment are to stretch the contracted structures causing the deformity, and to relax and then educate those muscles which will restore the muscle balance of the foot. The usual methods are by splinting with malleable iron, by adhesive strapping, by plaster-of-Paris, by club-foot tin shoe, and by operation (Thomas wrench, etc.).

To simplify description it will be assumed that the deformity is talipes equino-varus. The objective is to untwist each part of the deformity in turn—first the varus and then the equinus deformity. The correction of the deformity is not, however, sufficient. The overstretched muscles, which probably have never functioned correctly, must be stimulated and trained to contract along their proper lines of action—for example, the peronei must be made (by tickling the sole) to evert the foot. Later, as the child grows, it can be taught to evert and dorsiflex the foot voluntarily. From this moment it is allowed to walk.

The exact method of splinting employed is immaterial. The important thing is attention to the detail of its application by the same operator throughout the treatment.

#### 1. Malleable Iron.

This material is five-eighths of an inch wide and No. 18 gauge. Each splint should extend from above the knee to below the toes, be well padded on one side, and covered with jaconet.

The varus deformity is manipulated with the fingers until, if possible, only the equinus deformity is left. The limb is then covered with cotton-wool from above the knee to well below the toes, and the upper part of this secured in position with a few turns of special linen bandage. The foot is then held plantar-flexed and everted as much as possible, the malleable iron splint shaped to this deformity, and then placed along the outside of the leg and foot, and banded on with the same linen bandage from above downwards and from within outwards. The circulation is watched, and after twenty minutes the infant may be sent home, provided the colour of the toes is pink. This treatment is repeated daily until full eversion, voluntary and sustained, is produced.

Treatment of the equinus deformity then commences. A malleable splint consisting of a sole-plate and calf-piece, made out of one sheet of metal, with no twist at the junction of the two parts, is then applied. It is padded in the usual way, and is adjusted first to the sole in the equinus position, and then to the calf—that is, the splint is moulded to the equinus deformity. Each time the splint is removed the sole of the foot is tickled, in order to increase the power of eversion and dorsiflexion of the foot. Day by day the sole-plate is gradually dorsiflexed, thereby stretching the tendo Achillis, until full, sustained, active dorsiflexion is obtained. From this moment the child, if old enough, is encouraged to walk, adhesive strapping being applied occasionally to help in the eversion of the foot. When old enough to wear boots, these are wedged on the outer side of the sole and heel to maintain the correction of the deformity and encourage active eversion of the foot.

It is, however, seldom possible to carry out this ideal line of treatment without tenotomy of the tendo Achillis, which is performed under a general anaesthetic at the ninth month; the foot is kept dorsiflexed in plaster-of-Paris for at least six weeks. The knee is generally flexed and incorporated in the plaster to prevent the infant kicking it off. When the plaster is removed the usual muscle education follows.

### 2. Correction by Adhesive Strapping.

Only the very best strapping should be employed, as the infant's skin is exceptionally delicate;\* it should be about one inch wide. The foot is manipulated and held everted. A strip of adhesive plaster is then applied to the *centro* of the sole, well in front of the mid-tarsal joint, passing round the outer side of the dorsum of the foot, under the sole, and then up along the fibular side of the leg to above the knee, which is held flexed. This strip is kept in position by a band of strapping passed twice round the leg just below the knee, and another above it. Should further eversion be desired, a linen bandage applied from above downwards will suffice. As its action is cumulative, the circulation should be watched with great care.

This line of treatment is continued daily (with tenotomy of the tendo Achillis later if necessary) until full over-correction of the deformity is produced, and can be maintained by strong muscular action. The rest of the procedure is as already described under treatment with the malleable iron splint.

### 3. Correction by Plaster-of-Paris.

The foot is manipulated as before, and special cotton-wool applied from below the toes to above the knee. Plaster-of-Paris is then put on, to above the knee, the foot being held in a position just short of the maximum correction obtained. The knee-joint is of course flexed to prevent the plaster slipping off the limb in the course of the next few days. This method of attack is repeated at frequent intervals until the foot is completely corrected, or division of the tendo Achillis becomes necessary.

There are certain distinct disadvantages about this method—it is exceedingly difficult to apply to small children, so that it really acts as a corrective plaster. Moreover, it is apt to get soiled, and comes off the limb very easily. Further, minute attention has to be paid to the circulation, as the plaster may easily compress the limb, and even retard its growth. In older children the following modification gives excellent results:

The foot is corrected, and held everted; the knee is flexed to 90 degrees and cotton-wool applied. A plaster-of-Paris bandage is placed round the knee. Whilst this is setting another bandage is applied from within outwards across the sole at the level of the transverse arch so as to evert the foot; when this band is several layers thick the bandage is then passed from the sole along the outside of the foot and leg to above the knee, where it is held taut, everting and dorsiflexing the foot, and is then incorporated in the knee-piece. Another plaster bandage is then applied from above downwards so as to include the leg and remainder of the foot, and at the same time increase the eversion.

This is an excellent method, but difficult, and accused of causing knock-knee, a complication which the writer has never seen.

\*The "Zo" brand, manufactured by Johnson and Johnson, is very good.

### 4. Treatment by the Club-foot Tin Shoe.

As a rule this is used as a retentive, rather than a corrective, splint. It consists of a sole-piece and a calf-piece, united by a stem which projects slightly backwards to avoid pressure on the heel.

The foot is manipulated and everted, the sole-piece of the splint being moulded to just less than the amount of eversion obtained. A strip of adhesive strapping is then passed from the sole round the outside of the foot, across the dorsum and then underneath the sole again to the outside of the foot, which is then placed firmly on the sole-plate of the splint, and secured there by the free end of adhesive plaster. The rest of the limb is then bandaged or strapped in position.

At each manipulation the sole-plate is everted farther, and even dorsiflexed, though it is unwise to attempt the correction of more than one deformity at a time. When overcorrection has been obtained the child is allowed to walk. Should it be too young, then the splint is kept on until it can start to walk. In the former case the club-foot shoe may be used as a retentive splint for night wear.

### 5. Operations.

Operations should seldom be necessary, and then only in older children in whom the ordinary treatment by simple manipulation and splintage has failed; or in cases of neglect, or so-called "relapse." It may, however, be necessary to employ one of the following operations: (a) manipulation with the Thomas wrench, (b) tenotomies, etc., (c) bone operations.

(a) *Manipulation with the Thomas Wrench.*—In infants and small children the hands and fingers are sufficient to correct a club-foot. In older children the Thomas wrench must be employed—first the adduction, then the varus, and finally the equinus deformity being thoroughly overcome. A retentive splint, or better, plaster-of-Paris, with plenty of cotton-wool, is then applied.

(b) *Tenotomies, etc.*—The tendons of the tibiales muscels (antieni and postieni) need never be divided; the tendo Achillis, however, generally needs division or elongation. The plantar fascia may require division in moderate degrees of pes cavus; in advanced cases Steindler's operation is the best—unless, of course, the deformity is so great as to require a cuneiform tarsectomy. An x-ray film will decide if the latter be necessary. Open division of soft structures should be advocated before operations on bone are undertaken—for example, division of the deltoid and posterior ligaments of the ankle, and the scaphoid ligaments.

(c) *Bone Operations.*—These should only be undertaken in children over 8 to 10 years of age, in whom the ordinary routine measures have failed and x-ray films prove the presence of a bony block or blocks. In such cases cuneiform resection should be performed, with the base of the wedge upwards and outwards, the various joints being as far as possible left intact. Retention in plaster-of-Paris for several months is essential, and the after-treatment even more important than the operation. Astraglectomy is seldom necessary, and then only in the adult, due care being taken to ensure backward displacement of the foot. Internal rotation of the tibia is generally corrected *pari passu* with the manual correction of the foot, but in cases of neglect or relapse simple manual osteoclasis of the tibia will cure this deformity. Open operation is unnecessary, and to be avoided, as cases of non-union have been recorded.

Throughout this article talipes equino-varus has been taken as the type. The other deformities are treated along similar lines, the various methods of splintage being adapted accordingly.

The prognosis is excellent in those cases seen early, and fair in neglected and "relapsed" cases, and in those children who have already been operated upon. Treatment is more difficult, and the results not so satisfactory, in children with "stubby" heels, talipes calcaneo-valgus, or simple mid-tarsal varus.

The keynote of success in the treatment of congenital club-foot is immediate splintage by simple means by the same operator throughout.

## DIABETIC TREATMENT SIMPLIFIED.

BY

FRANK C. EVE, B.A., M.D.CAMB.,

F.R.C.P. LOND.,

PHYSICIAN, ROYAL INFIRMARY, AND TO CHILDREN'S HOSPITAL, HULL.

Few will deny, least of all general practitioners, that the treatment of diabetes has now become very complicated, and, in my opinion, there is a real danger of the main issues becoming fogged in a cloud of bewildering details. The main issues are: (1) the quantity of sugar excreted day by day; (2) the presence or absence of ketones; (3) treatment by regulating the quantity and quality of the diet, or by giving insulin if dietetics prove inadequate; (4) the blood sugar (in special cases).

The ground can be cleared by distinguishing clinically between cases of simple glycosuria, which are common and usually unimportant, and stubborn diabetes, which is uncommon and serious. This paper deals with genuine diabetics who are living at home.

*Measurement of the Daily Excretion of Sugar.*

Obviously it is a cardinal necessity that both doctor and patient should have daily knowledge of this over prolonged periods. Without this knowledge treatment cannot be either intelligent or effective. Yet, in private practice, even at the present day, this indispensable minimum of knowledge is

CHART 1.—Diabetes and acute phthisis in a woman, aged 21. Showing the effect of insulin in plotting the curves together when diet was powerless to do so. A, 20 units of insulin injected; B, 15 units of insulin injected; C, 10 units of insulin injected; D, strict diabetic diet. The patient's appetite was poor from August 22nd till September 14th, after which it improved, needing more insulin.

lacking, or rather is available to doctor and patient only at rare or occasional intervals. The daily variations in sugar excretion—which I know to be very wide—are hidden: only the occasional testing days are illuminated.

This deficiency, during the last four years, I have remedied by a very simple method whereby the patient himself is able to measure and record on a chart the daily variations in the excretion of his sugar. I have yet to meet the private patient who was not able and willing to do this, usually with enthusiasm. The method is described at the end of this paper.

Now what does this daily chart of sugar excretion enable us to do?

1. The doctor can see at a glance whether in his absence the patient has been going on well and has been obeying instructions. In the green-pea season a patient who was too fond of them was detected by his chart. A paint manufacturer's sugar was seen to increase owing to worry when the price of oil jumped. A small boy in hospital crept from his cot at 3 a.m. and devoured a box of chocolates. Chart 3 reveals this and his other falls from grace. Further, the patient himself can see when he makes mistakes. He takes pride in producing a chart without such blemishes, and hence is more careful in his diet. Also he is rewarded visibly for his starvation days if they are imposed (Chart 4).

2. If insulin is being given in private practice one has to leave a little sugar (1 or 2 grains per ounce) in the urine as a safeguard against hypoglycaemia. By the help of the daily chart (see Chart 1) this can easily be done by adjusting the amount of insulin or bread. Without a daily chart the steering must be very wild—and dangerous, I would think.

3. The daily chart enables the practitioner to send calories to the devil, where they belong. Calories are well enough in a research laboratory, but human patients are not engineering propositions. Each man varies in his efficiency,

both digestive and metabolic; he varies in respect of the calories he has to spend in exercise or in keeping up his body heat in variance with his house, his clothes, and the weather. Then there are the varying hosts of bacilli which we feed in our intestinal canal and which form so large a proportion of our faeces.

For reasons of this kind it is, I fancy, a pseudo-scientific presumptuousness to pretend to be able to work out by arithmetic a cast-iron table of a man's food requirements. On the other hand, Nature does give a man an appetite varying roughly with his daily needs (bulimia is quite exceptional in diabetes and at any rate laughs at calories). And if restrictions of the quality of his diet are shown by the sugar chart to be inadequate, the patient's quantity of food must be restricted, especially if he weighs too much.

What I do is to put the diabetic gradually on to a diet free from carbohydrate. If sugar persists and no ketones appear, diminish the quantity. If ketones appear, 1 to 3 ounces of bread (weighed) is added, and enough insulin injected to bring the sugar almost to zero. Or weekly "starvation days" on greens, bouillon, and coffee may obviate the necessity for insulin.

I do not claim that the daily chart of sugar excretion is a perfect method, but I have found it reliable, adequate, and most helpful. A daily chart of the blood sugar would in some ways be more perfect. But this fluctuates violently from hour to hour; it yields no summative measurement as the urine does; and, at any rate, daily blood sugar tests are impracticable in private practice.

4. Another point of interest (and perhaps of novelty)

CHART 2.—Simple glycosuria easily cured by diet; no ketones. Diet makes the two curves coincide.

shown by the daily charts is that occasionally the urine, when fermented, has the same specific gravity as water. At the beginning of the little boy's chart (3) this occurred for two consecutive days, and also in Chart 4. Weak sugar and water does the same when fermented. If this be verified by more accurate methods it would mean that the kidneys secrete no other solids than sugar on those brief occasions, although the patient's health does not seem affected.

*Insulin.*

The main practical points are:

1. Insulin is something which somehow enables a diabetic to burn up sugar like a normal person, but does not enable him to store it as glycogen.

2. Insulin can in this way cause the blood sugar to sink to a dangerously low level (hypoglycaemia). This danger can be guarded against if the patient always carries about with him eight large lumps of sugar (1 or 2 ounces of barley sugar—Macleans) and promptly eats them all if he feels queer after an injection of insulin. Two grams of glucose are supposed to keep busy one unit of insulin; from which I reckon that eight average lumps of sugar would act as antidote to 15 units of insulin.

3. Insulin is given two or three times a day, just before a chief meal, which if possible should contain 1 ounce of bread; 10 to 50 units daily is the usual range of dose; more is seldom useful.

4. The patient can be taught to inject it into the pinched-up skin of the thigh, under weekly supervision. A trained nurse is better, but a doctor cannot be at hand three times a day before meals.

5. Insulin has to be acid; in a few subjects this causes painful lumps. It is said that neutralization in the syringe by sterile sodium bicarbonate solution of proper strength prevents this irritation and does not impair the action of the insulin.

6. As to blood tests with insulin, I have rarely found them helpful (see "Coma in diabetes"), for it is unattainable

in private practice to keep the blood sugar normal. You dare not even keep the urine quite free of sugar in insulin cases.

7. The risk of giving insulin in unsuitable cases will be practically eliminated without blood tests (a) if you first try to cure all cases by diet alone; (b) if ketones are present, and abundant sugar, insulin is surely needed; (c) leaky kidneys (renal glycosuria) are a real but uncommon danger. These cases may be recognized by their uncanny failure to improve with diet, by their good health, by the absence of ketones, and by the absence of glycosuria three hours after a good starchy meal. A blood sugar will decide the matter by showing a low renal threshold for sugar. So also, I imagine, would the absence of rhythmic oscillation in a weekly starvation chart (as Chart 4); but

venously nowadays). We must certainly give insulin freely; but the terrible question is, how much? Either timidity or rashness may kill. If you can have a blood sugar test every hour or so, then you are on sure ground. But this must not entail delay. Failing this, it seems to me you must guard your big doses of insulin with glucose. This will ensure against hypoglycaemia, and by its combustion it should destroy the poisonous ketones. However, some authorities are opposed strongly to injecting sugar, though their reasons seem weak to me. Agreement is not yet reached, but if you can inject sugar you do not require blood tests.

There is no time in coma to trifle with half-measures. Hence intravenous injections are needed, starting with 20 to 40 units of insulin, 40 to 80 grams of glucose in

Chart 3.—Diabetic boy aged 8. The shaded area between the curves is the quantity of sugar in the urine day by day. Sugar reappears after Christmas indiscretions.

I have seen no such case in the last four years. To insist that we should test the blood of every glycosuric patient before giving insulin so as to avoid this fairly obvious bugbear seems to me absurd.

8. I do not recollect seeing a single ill effect attributable to insulin, while the benefits are notorious. But if in an emergency you are nervous of causing hypoglycaemia you can guard the insulin with sugar, as above.

#### Ketones.

Ketones, such as acetone and diacetic acid, are half-oxidized fats. Their presence in the urine is revealed by the nitro-prusside test or the ferric chloride test; I prefer the latter, as the former is too sensitive and becomes a scaremonger.

If the addition of two drops of liq. ferri perchlor. fort. to the urine produces a dark-brown colour then ketones are present in dangerous amount, and must be got rid of, lest coma supervene. Ketones are far more pregnant with danger than sugar, and are often produced by too strict a dietary. They indicate that the fats in the system are not being properly burnt up. Now how can these poisonous half-oxidized ketones be thoroughly and harmlessly burnt up? By giving more carbohydrate food, for the fats are combusted in the furnace of brightly burning carbohydrates. But the special weakness of the diabetic is that he cannot burn up his carbohydrates properly. Hence, to get rid of ketones, it is often useful not only to give extra carbohydrate, but also to give insulin, which has the mysterious property of enabling the diabetic to burn up sugar like an ordinary person. So that if ketones appear, watch for coma, ignore the sugar in the urine, and treat the much greater danger by giving alkalis freely and more bread. And if you find that large doses of alkali fail to make the urine alkaline, then the peril of coma is menacing indeed. Ten grains of sodium bicarbonate should alkalize a normal urine; so try your ketosis patient with 20 grains. An hour afterwards boil and cool the urine in a test tube and test with blue litmus paper.

#### Coma in Diabetics.

Here I can only touch upon the main principles. Since the coma is probably due to poisoning by the "acid" bodies formed by the imperfect combustion of fats, we are told to give alkalis freely by mouth or rectum (not intra-

800 to 1,600 c.cm. of water. Then you must feel your way by results, but 80 to 100 units or even more may be needed in the first day. Croton oil, strychnine, and camphor will also probably be indicated. I have seen nothing in medicine more dramatic than the swift escape from the very jaws of death into the enjoyment of apparent health which usually follows this treatment.

Persistent vomiting, with coma, is a very fatal complication. Although albuminuria may be slight, I have wondered if the real poison was uraemic in nature; but I have not yet had a chance of measuring the blood urea. Certainly, after long periods of diabetic overwork and irritation, the kidneys frequently show signs of wear and injury. Thus, numerous casts, albumin, and diminished sugar are often found in the urine in coma.

#### Exercise.

Exercise in moderation is important in diabetes to help the combustion of sugar to carbonic acid which takes place in the muscles. Gardening is an excellent hobby for diabetic patients, and often makes them look the picture of bronzed and ruddy health. Bed should be prescribed only during starvation or illness.

#### Method of Domestic Estimation of Urinary Sugar.

The apparatus required is: (1) A urinometer with a long stem indicating clearly specific gravities 1000 to 1050. This, and its glass cylinder, should have a case for travelling. (2) An engineering student's exercise book of squared paper. Its left-hand margin is also graduated 1000 to 1050.

(3) A thermos flask, pint size. (4) A pennyworth of yeast, fresh twice a week.

#### Method.

Every night the specific gravity of the urine is taken when warm. The thermos flask, which has been warmed and cleansed with hot water, is filled with the warm urine; a piece of yeast the size of a small walnut is added and shaken up. The flask is corked loosely (or with cotton-wool) and wrapped in blanket. Next morning the specific gravity is again taken. It will be less, because all the sugar has been converted by the yeast into carbonic acid gas (mainly). Let us suppose the gravities before and after fermentation were 1040 and 1020. A red dot and a black dot will be placed at their proper heights in the first column of the squared page. Next day another pair of dots will appear in the next column. Thus will be spun out an upper and a lower curve, one red and the other black. The space between these curves represents the excretion of sugar in grains per ounce. The object of treatment is to pinch these two curves together. When they coincide there is no sugar,

Chart 4.—Showing effect on sugar excretion of Sundays on greens only. The two curves approximate at the week-ends (no sugar). From a case of diabetes with myxoedema.

and it is well to mark these days by a red dot within a circle.

If the morning urine alone is recorded the results will be more constant, more flattering, and less useful. The night specimen is best for a patient who does not always urinate at once. A twenty-four hours specimen is not much better; it is a nuisance to warm, and is only available for the home-keeping patient.

**Ketone Test.**—Every morning the patient watches two drops of liquor ferri perchlor. trickle down the near side of the urine glass. If it changes from yellow to dark brown the doctor must be informed that day.

## THE SCHICK TEST AND ACTIVE IMMUNIZATION AGAINST DIPHTHERIA.

BY

JAMES P. WATT, M.A., M.D., D.P.H.,

CONSULTING MEDICAL OFFICER OF HEALTH FOR ABERDEENSHIRE.

THE burgh of Fraserburgh has, according to the Registrar-General's estimate for 1923, a population of 10,367. The births in that year numbered 257, and the average for the preceding five years was 287.

### *Incidence of Diphtheria in the Burgh.*

Since 1900 there has been in Fraserburgh, as in other towns in the kingdom, an increasing incidence of diphtheria, as the following total notifications indicate:

1900-04	...	...	...	...	48
1905-09	...	...	...	...	127
1910-14	...	...	...	...	164
1915-19	...	...	...	...	61
1920-23	...	...	...	...	401

In view of this increased incidence and the cost of hospital isolation, the Public Health Committee, on my recommendation, decided to try the newer measures of prevention by toxin-antitoxin inoculation, and accordingly, on March 25th, 1924, decided to open a series of clinics, free of charge, for the inoculation of children under 5. The clinics were to be held once a week in the Town House, and to be conducted by the local medical practitioners in rotation, who had cordially agreed to give their assistance.

In recommending that children under 5 should be dealt with first, I was influenced by the fact that at this age reactions either do not occur or, as Dr. Park says, are "slight or negligible." The susceptibility at this age to diphtheria (70 to 80 per cent.), and the fact that half of the diphtheria deaths are among children under 5, were also reasons for trying to get as many of them as possible inoculated. It seemed likely also that the absence or slight nature of the reactions in young children would lead parents more readily to give their consent for the inoculation of the older children when the schools were dealt with, and this proved to be the case.

The first step in the way of propaganda was the distribution through the schools of a leaflet to all parents or guardians having children attending school, explaining the purpose of the clinic and the value of toxin-antitoxin inoculation, while the same leaflet was shown in large posters in shop windows and other places throughout the town.

The following is a copy of the leaflet.

### DIPHTHERIA PREVENTION.

#### To Parents or Guardians:

Diphtheria is a most dangerous disease, and is particularly fatal to young children. Of a hundred deaths from diphtheria, 80 are under 10 years of age, the larger proportion being under 5.

Your children need not have diphtheria. It can be prevented.

Some people are able to resist the germs of diphtheria, others are not.

A simple method—painless and harmless—has been discovered to find this out. It is called the Schick test.

If this shows that your child does not resist diphtheria germs, it can be inoculated and protected against diphtheria.

As almost all children over 6 months and under 5 years of age are liable to contract the disease, it is not necessary to apply the Schick test to them. They should all be inoculated and protected. The inoculations are followed by no constitutional reactions and very little local irritation.

This method has been used for several years, and so far almost no one who has been so protected has got diphtheria.

Diphtheria can be stamped out and many lives saved every year if mothers will have this done and protect their children.

The Town Council of Fraserburgh have resolved as a first step to give parents an opportunity of having all children under 5 years of age and over 6 months protected free of charge. They have accordingly arranged to open a clinic in the Town House to which children under 5 may be brought. The clinic will commence on Wednesday, the 11th June, and will continue for six weeks, a meeting being held each Wednesday at 2.30 in the Town House. This clinic will be conducted by Dr. Beddie.

Subsequent clinics will be conducted by the other doctors in rotation.

To obtain complete protection each child will have to be brought to the clinic three times, at a week apart.

Articles giving a more complete explanation of the Schick test and toxin-antitoxin inoculation were published in the Aberdeen and Fraserburgh newspapers, and we were greatly indebted to the press for the strong support they gave us in the work. I carried out also, as far as time permitted, a personal visitation of the homes, more especially in the poorer parts of the town where diphtheria had been most prevalent.

**Clinics.**—The first clinic was opened on June 11th, but there was no attendance on the first three occasions. To the fourth clinic, however (July 2nd), 5 children were brought, and to the fifth 10. To the next three clinics 4, 3, and 0 came forward—the total attendances being 19, 17, and 6. To the eight clinics, therefore (June 11th to July 30th), only 22 children had been brought. This was largely due to the fact that, owing to absence on holiday in July, I was unable to continue the visitation of the homes which I had begun in June. On my return this visitation was energetically resumed, and the numbers coming to the clinics began to increase. On August 6th, 15 fresh children, and on August 13th 41, came, making the total at this latter clinic 57. With the consent of the Public Health Committee a second weekly clinic was opened on August 18th, and as the numbers continued to grow a third clinic was commenced on September 5th. These three clinics were carried on throughout September, October, and November, while one of them was continued into December. Apart from school children, there was a total attendance of 596 children under 5, 92 per cent. of whom were inoculated thrice, while of the remaining 47, 25 had two inoculations and 22 had one; 780 children from the schools were also inoculated at these clinics.

**Schools.**—On September 4th, by which date 183 children had attended the clinic, the town council resolved unanimously to take measures to deal with the schools, and authorized me, with the assent of the education authority, to ask for the consent of parents to inoculate those under 7 without Schick testing, to use the Schick test for those over 7 and inoculate those found Schick-positive, and to obtain such assistance as might be necessary. I did not think it desirable to apply the Schick test to children under 7, and the experience of applying the Schick test in the schools has confirmed me in this view. The head masters and mistresses of the schools were approached, and they most kindly promised their hearty co-operation. With their assistance consent forms were distributed to all parents and guardians; the forms were of two kinds, according as the children were under or over 7. Class sheets were provided, and these were very kindly filled in by the teachers of each class from the consent forms returned. No propaganda was employed further in connexion with the schools, other than had already been carried out for the children under 5. There are five schools in Fraserburgh, of which three are attended by children under 7—namely, the Infant, the North, and St. Peter's Episcopal. St. Peter's and the North School have children also up to 14, and the Infant School to 11. The Central is attended by children from 8½ to 14 years; the Academy pupils are over 12 years.

*Children under 7.*—For children under 7 consent was obtained for the inoculation of 324—namely:

St. Peter's Episcopal ...	29=93% of children under 7
Infant ...	222=87% " "
North ...	73=61% " "
	324=80%

*Children over 7.*—For children from 7 to 14 consent was obtained for 1,239. These belonged to the following schools:

Central ...	608=90% of children over 7
Academy ...	202=88% " "
St. Peter's ...	100=86% " "
Infant ...	143=85% " "
North ...	184=61.5% " "
	1,237=82.2%

The percentages of consents are very high. Dr. Park, speaking of the New York schools, says that these varied "from one-fourth to three-fourths, depending upon whether the teachers were enthusiastic or not in their co-operation," while the average for sixteen Edinburgh schools, as given by Dr. Benson,<sup>1</sup> was 42.3 per cent.

#### Schick Testing and Results.

The testing was carried out by a medical staff of seven, under the able supervision of Dr. Anderson, superintendent of the City Hospital, Aberdeen, who had been kindly allowed to assist in the work. In all cases a control test was carried out on the right arm. The Schick testing occupied two and a half days (October 13th to 15th), and the results were read on October 17th and 24th.

Of the 1,239 children, 456 were found to be Schick-positive and 783 Schick-negative. The following table gives the results:

Total Schick-positive (including 43 pseudo-positive) ...	456=36.8%
Total Schick-negative (including 130 pseudo-negative) ...	783=63.2%

The percentage of Schick-positives for each school was as follows: Infant, 49.6; Central, 48; Academy, 43; North, 39; and St. Peter's, 24. It is interesting to note that the average of Schick-positives among 83,000 children in the New York schools, as given by Dr. Park in 1922, was 35.7.

The inoculation of the school children was carried out at the clinics in the Town House along with the children under 5; the total number of inoculations done at these from June 11th to December 24th was 4,039. The highest numbers attending a clinic were 198, 188, 186, and 175.

The total number of children from 6 months to 14 years of age inoculated was 1,376. Of these, 1,290 (94 per cent.) completed the three inoculations. In addition, 12 teachers were inoculated (2 male and 10 female).

The numbers inoculated at the age of 7 and under were: from 6 months to 1 year, 61; second year, 142; third year, 141; fourth year, 150; fifth year, 166; sixth year, 153; and seventh year, 123.

One of the most gratifying features of the work was the entire absence or the comparatively slight character of the reactions following the inoculations of the children under 5. In the case of children over 5 also we were fortunate in having no reactions of a serious character.

#### Effect on School Attendance.

That the reactions in those over 5 were either absent or not serious is shown by the reports as to the amount of absenteeism in the schools following upon the inoculations, with which the headmasters and headmistresses very kindly supplied me, and which show that the inoculations had no noticeable effect on the school attendance. One may be given as an example:

In the Central School the percentage attendances from October 17th, the week of the Schick test, to December 5th, a week after the third inoculation, were as follows: 93.4; 91.3; 88.1; 92.1; 90.3; 90.4; 90; and 90.5. The inoculations were done in the three weeks from November 14th to November 28th. "The change

in percentage attendance," the headmaster points out, "is not noticeable."

The reports for the other schools were in similar terms.

#### Incidence of Diphtheria amongst those Inoculated.

Amongst the children who were inoculated, three cases of diphtheria occurred down to February 14th. The first was a boy, aged 6, inoculated on October 12th, 20th, and 29th, who developed diphtheria on November 30th. His attack was so slight that he recovered without the administration of antitoxin. The second was a girl, aged 4½ years, who developed diphtheria on December 13th, forty-five days after the date of the third inoculation, which was on October 28th. There was hardly time, therefore, for her to have developed protection. The third case was a child, aged 2½ years, who was notified on January 21st, 1925. She had been inoculated on August 13th, 20th, and 27th, 1924, so that there was time for protection to have developed. Two points, however, have to be kept in view: first, that protection may not be complete for a year; and secondly, that a certain percentage of cases are not protected by the first series of inoculations. All three cases made a good recovery. I may add that during 1924, 43 cases of diphtheria were notified in Fraserburgh, 19 being under 14 years of age. This year (1925) 5 cases in all have been notified, all under 14. One of these was the third case referred to above as occurring amongst those who had been inoculated. The other 4 cases had not been inoculated. One of them had had diphtheria four years ago. Last year two girls, 9 and 12 years of age respectively, who had been tested and found Schick-positive, developed diphtheria before the inoculations could be carried out.

#### Suggestions.

As the result of my experience in Fraserburgh, I have formed the opinion:

1. That, for the reasons mentioned in the earlier part of the paper, it is better to commence the work with children under 5, and that even in an area where antivaccinators are numerous (and in Fraserburgh the percentage of unvaccinated children is from 30 to 40) the work may be successful if carried out with energy and perseverance.

2. That the most successful form of propaganda is the visitation of the homes, and in this latter work the fathers, as well as the mothers must be approached and persuaded. I frequently found that the rather sharp reactions which had sometimes followed inoculations, such as those against typhoid, paratyphoid A, and paratyphoid B, in the late war, had made many of the men who had experienced them averse to inoculations generally, and they had to be convinced that the inoculations of the children with toxin-antitoxin would not be followed by similar reactions.

3. That if prejudice against it amongst the working class is to be avoided, the work should be carried out simultaneously among the better class.

4. That it is very important that medical practitioners be asked to co-operate to the utmost extent. In the support I received from the medical men in Fraserburgh I was singularly fortunate, and to their help the success of the work was largely due. I should like to add also that the district nurse rendered me the greatest assistance, and that she was present at all the clinics and helped most effectively in the propaganda work.

I think there can be no doubt that if toxin-antitoxin inoculation against diphtheria were adopted generally, it would lead to a great diminution in the incidence of the disease and to a still greater diminution in the case-mortality. Sir George Newman admits that diphtheria remains "one of the most baffling diseases from the point of view of the public health administrator, and that the mortality from it has not shown any decline during the past ten years." It was the failure of the usual administrative measures accompanied by a high case mortality that led Dr. Park and his coadjutors to introduce these measures in New York. They found that the number of "carriers" in times of epidemic made the control of diphtheria by the ordinary methods of little or no avail.

The Town Council of Fraserburgh and its Public Health Committee have supported wholeheartedly the various measures recommended, and faced the rather heavy expenditure involved without hesitation and in a highly public-spirited manner, seeing that they were about the first authority in this country to adopt these new measures on a large scale.

## JEJUNO-COLOSTOMY IN THE TREATMENT OF ACUTE SPREADING PERITONITIS.

BY

A. J. BLAXLAND, M.S.LOND., F.R.C.S.,  
 SURGEON, NORFOLK AND NORWICH HOSPITAL.

THE prognosis of acute spreading peritonitis has improved very greatly since the universal recognition of the importance of removal of the focus of the infection (commonly the appendix), drainage, rectal salines, and Fowler's position. Unfortunately cases occasionally occur in which the application of these methods fails, and hitherto the outlook in such circumstances has been almost hopeless.

Mr. Sampson Handley's work on this subject cannot be too widely known. It is of great value, and his line of treatment offers a hope in truly desperate cases. He embodied his views in a Hunterian Lecture, which is published in a finely illustrated article in the *British Journal of Surgery* (January, 1925). The chief points in this lecture may be summarized as follows:

1. The importance of intestinal paralysis in severe forms of peritonitis.
2. In some cases the infection itself, and the toxæmia resulting, are so intense that no treatment is of avail.
3. In others, less severe, but progressing more slowly to a fatal issue (in spite of removal of the septic focus, drainage, Fowler's position, etc.), the main feature is failure to produce an action of the bowels. Death in these cases is due not so much to absorption from the peritoneum as to paralysis of the bowel wall.
4. This paralysis does not usually affect the whole of the bowel, as is often thought to be the case.
5. The paralysis affects, at first, the pelvic coils of the ileum and the pelvic colon (hence the name of "ileus duplex" given some years ago to this condition by Mr. Handley). Later, the peritonitis spreads upwards to the hypogastric region, and a large amount of small intestine becomes involved, but the inflammation does not often reach the upper abdomen. "General" peritonitis is rare.
6. The signs of spreading "hypogastric peritonitis" are tenderness, rigidity, distension, and immobility of the abdomen below the umbilicus; rising pulse and falling temperature; anxiety and extreme discomfort; vomiting which is vigorous and in considerable amount at not frequent intervals (and not yet effortless, frequent, and in small quantities—which is a final hopeless stage), and failure of turpentine enemata, combined with hypodermic injections of pituitrin and eserine, to emit flatus.
7. Treatment is designed to overcome the obstruction which exists in the small bowel and also in the pelvic colon. If the obstruction is relieved, the peritonitis tends to subside. Jejunostomy has obvious disadvantages. The procedure advocated is short-circuiting combined with a temporary caecostomy; in the pelvic stage an ileo-caecostomy with caecostomy; in the hypogastric stage a jejuno-colostomy with caecostomy.

Mr. Handley reports four cases with spreading hypogastric peritonitis, in which he performed jejuno-colostomy and caecostomy. Three of these completely recovered. He informs me that none of these patients have suffered any disability from the short-circuiting, such as diarrhoea or loss of weight. Presumably the anastomotic opening tends to close—or ceases to function—when the peritonitis sub-

sides and the obstruction disappears. In the fourth case, although the infection was so severe as to cause pyæmic abscesses, from which the patient died on the twenty-seventh day, yet the peritonitis entirely subsided.

A similar case that I have treated recently furnishes another proof of the correctness of Mr. Handley's views and the hopefulness of the treatment that he recommends.

In my case the patient had acute spreading peritonitis, and was very obviously going downhill. A jejuno-colostomy was performed with immediate beneficial result, and the peritonitis completely subsided in two weeks' time. A sloughing ischio-rectal abscess unfortunately developed, and the patient died from its effects on the twenty-sixth day after the operation.

It will be noticed that enecostomy was not done in this case. The pelvic colon is not necessarily involved in the inflammatory paralysis, though this would presumably be so when it has a long loop which lies in the pelvis. Three days before the short-circuiting was performed a large collection of pus had been drained from the pelvis, and an enema administered soon after had given a good result. This convinced me that the pelvic colon itself was not paralysed, but only the small intestine, as was subsequently verified.

As a rule, however, it would, I presume, be wiser to combine enecostomy with the anastomosis.

A married woman, aged 47, had mild pain in the abdomen on January 21st, 1925, and vomited once. The next day she called in Dr. Poole of Norwich. The temperature was 99° F. and the pulse below 80. She had slight abdominal pain, but there were no local signs, either abdominally or on pelvic examination, sufficient to enable a diagnosis to be made. The symptoms remained about the same until January 26th, when the abdomen became distended, and the patient vomited two or three times. An enema gave a good result.

### First Operation.

I saw the patient in consultation with Dr. Poole on January 27th. The symptoms were increasing. There was marked distension of the abdomen, but no rigidity. The temperature was 101.5° F. and the pulse 80. A tender tense swelling could be felt in Douglas's pouch. Under general anaesthesia an incision was made in the posterior fornix of the vagina, and a large collection of thin, stinking pus and a loose faecal concretion were evacuated. A drainage tube was inserted. The presence of the concretion in the pus confirmed a diagnosis of appendicitis.

The next day (January 28th) the temperature was normal and the bowels were opened well after a soap enema. On January 29th the distension recurred; there was some forcible vomiting. A small amount of flatus was passed after giving eserine and pituitrin. The next day the distension was very great. Vomiting continued, forcible and in moderately large quantities. No flatus resulted after repeated injections of eserine and pituitrin and turpentine enemata. The pulse had risen to 96, and the patient was obviously very ill.

### Second Operation.

Right paramedial laparotomy was performed. Very distended and intensely congested coils of small bowel were found, with patches of lymph gluing them together in places, up to the level of the umbilicus. The transverse colon was empty and not inflamed. The small intestine was incised at two places, and gas and liquid contents evacuated. The incisions in the bowel were closed. A loop of the middle or lower part of the jejunum, which was distended and somewhat inflamed, was anastomosed (side-to-side) with the middle of the transverse colon. A cigarette drain was inserted down to the pelvis and the laparotomy wound closed. Two pints of glucose in saline solution were given intravenously.

On February 1st flatus passed in quantities; there was less distension. The following day there was a good liquid result from enemata, and on February 3rd good natural relief; there was still less distension.

On February 6th there had been no operation a week before. There was still some pyrexia, and the tongue was dry and raw, but the patient was taking nourishment well. She was obviously suffering from septic absorption, and antistreptococcal serum was given. On February 12th there was still some pyrexia; the tongue was still dry and raw. Antistreptococcal serum was given. Two days later a stinking left ischio-rectal abscess was opened.

By February 18th the general condition had improved; the abdomen was quite soft, and there was no distension. The next day the tongue was moist, and she was taking food well. The bowels acted two or three times daily.

On February 22nd the patient had sudden acute diarrhoea, and she was very ill. The tongue was dry and raw. Two pints of glucose in saline were given intravenously. A large slough was discharged from the ischio-rectal abscess. The next day she was semi-conscious. Three pints of glucose in saline were given intravenously.

The patient died on February 24th.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## ANENCEPHALIC FOETUS.

THE following outline of a somewhat unusual occurrence is perhaps of general interest. I was recently called by a midwife to the confinement of a multipara, aged 29, and on examination I found a hand presentation. I administered an anaesthetic, and, on inserting my hand into the vagina, a small foetus was suddenly expelled. Its length was 8½ in., and it presented a most curious, and at first glance an ape-like, appearance, with long arms extending to the lower third of the legs, long fingers, narrow heels, and broad toes. It was anencephalic, and the skin over the dorsal region was transparent, showing a cuirass-like appearance of the vertebrae and rudimentary ribs. The mouth was open, with the tongue protruding; the penis and scrotum were only slightly developed. A pale-coloured small

placenta followed. On further examination another hand was felt, and in a short time a well formed seven months male child was born alive, followed by a normal healthy placenta; this child, however, lived only one hour. The woman had had three confinements, all of which were normal, with living healthy children. Her mother had borne twins, and the husband's first wife died after giving birth to twins—all the children being healthy. The accompanying illustrations are reproduced from photographs of the abnormal child taken shortly after its birth.

Johnstone, Renfrewshire.

## A CASE OF ACUTE GENERAL TETANUS.

THE following record of a boy who recovered from severe general tetanus seems of sufficient interest to merit publication. A similar case, in which recovery from tetanus took place after treatment with antitetanic serum and chloretone, was reported from the Royal Surrey County Hospital, Guildford, in this JOURNAL in 1910 (vol. ii, p. 1402) by Mr. R. A. Hobbs and Mr. E. W. Sheaf.

A boy, aged 14, injured his hand with a toy pistol on January 8th. Eight days afterwards spasms of the jaws were observed. When admitted to hospital, on January 19th, trismus, risus sardonicus, and opisthotonus were marked. Spasms occurred every few minutes. There was a small punctured wound in the left hypotenar eminence.

Before admission 15,000 units of antitetanic serum had been injected into the theca and 3,000 subcutaneously. A further dose of 3,000 units was given subcutaneously on admission, and the boy was placed in a dark room away from all external stimuli. The wound was excised and oxygen bubbled into the surrounding tissue.

Morphine, chloral, paraldehyde, and bromides were tried during the following two days, but failed to relieve the spasms, and chloroform anaesthesia had to be produced on three occasions. On the third day large doses of chloretone were given by the rectum, and the spasms ceased almost entirely. This treatment was kept up for nine days—sometimes as much as 90 grains of chloretone being given by the mouth in twenty-four hours. If discontinued the spasms recurred, but on repetition of the drug calm sleep supervened. No toxic symptoms were noticed.

During the first nine days antitetanic serum was given daily (5,000 units subcutaneously and intramuscularly). On the tenth day both the chloretone and the antitetanic serum were discontinued, and no further spasms ensued.

I am indebted to Dr. Arthur Saunders for his permission to publish this case.

The chief points of interest were the remarkable manner in which the spasms were controlled by chloretone, and the rarity of recovery after such a short incubation period.

London, W.6

## Reports of Societies.

## THE PLEA OF INSANITY.

At a meeting of the Medico-Legal Society held in London on May 19th, with the President, Lord Justice ATKIN, in the chair, Dr. LIONEL A. WEATHERLY read a paper entitled "The medical aspect of some murder cases in which insanity was the defence."

Dr. Weatherly said it was well known that ever since 1843, when the four judges made the rule which was still the law regarding criminal responsibility of the insane, the medical experts in mental diseases had unanimously objected to this rule as being unscientific and unjust to many an insane criminal. They must, however, recognize that criminal responsibility was a purely legal question, and that the law, which was the formal expression of the will of the community, was the sole authority in defining this responsibility. But while the law had more or less stood still for generations, medicine was a science which was ever advancing; it was now able to show how disease could affect the intelligence, the imagination, the reasoning power, and also the affective side of what was called mind—namely, the emotion and the will—affecting it in such a way as to make the ruling by which criminals were judged at the present time, when insanity was the defence, unsound and unfair. Personally, he deprecated heated arguments regarding the M'Naghten rulings between law and medicine. What both lawyers and doctors desired could only be justice to the prisoner and the safety of the community. Alienists should study carefully the interesting evolution of the legal rulings, and lawyers should do their best to gain a knowledge of the diseased mind in the fullest application of that term. Had the four judges who laid down the M'Naghten rulings lived for a few days in the wards of any of our mental institutions they would have given very different answers to the questions submitted to them. Excluding idiots, imbeciles, and many chronic demented, they would have found very few of the inmates of whom they could confidently state they had no proper knowledge of right and wrong. Those judges would have seen cases of general weakening and deficiency of the intellectual powers, of the will, and of the control of emotions, where the subjects were yet capable of distinguishing right from wrong. They would have conversed with patients with delusions, hallucinations, and illusions of one or more of the senses, and yet with a clear knowledge of right and wrong. They would have had pointed out to them patients who at times were subject to transitory fury, or who reasoned insanely on sane premisses, or vice versa, and yet all these patients would have that knowledge which made them in the eyes of the law of the land responsible beings.

Medical experts were often accused of showing distinct bias in their evidence in these cases, and it might be that some were too emphatic in their statements; but it must not be forgotten that if a medical expert, with years of experience of mental diseases, was satisfied in his own mind from his examination of the prisoner and of his whole history that he was insane, he had that feeling so well expressed by the American counsel Mr. W. H. Seward: "I should be guilty of murder if in my present relation I saw the executioner waiting for an insane man and failed to say and failed to do what in my belief the law allowed." The task of the mental expert was more difficult than that of the pathological expert. The mental expert was not able to produce microscopic slides showing the abnormality in the prisoner's brain cells, nor could he give any arithmetical data as to the underweight and the will power of the prisoner; he could not demonstrate the prisoner's emotion in a glass bowl and prove to the jury that, while healthy emotion should be pure white, the prisoner's was of a dirty yellow colour. It had often been said that the mere fact that doctors would go into the witness-box and give evidence diametrically opposite minimized the value of the evidence given by the alienists in these trials, but surely this was not true reasoning. Judges even differed in their opinion of law, and judgements were often upset in the Appeal Court, and again by the House of Lords.

They had recently heard the Lord Chief Justice's emphatic statement that the Appeal Court would hesitate long before it transferred to medical experts the determination of questions upon which the jury, after listening to conflicting views, had arrived at a unanimous conclusion. They must all heartily endorse that statement, which, to his mind, showed the necessity of some alteration in the existing law regarding insanity as a defence. Did it not often happen that the evidence given in a court of justice by an alienist that the prisoner was suffering from a mental disease was ridiculed, or his opinion very much discounted, and yet that same alienist was able to record an opinion in the condemned cell upon which the Home Secretary was able to override the unanimous verdict of the jury, and to save the condemned prisoner?

Dr. Weatherly detailed a number of cases in which he had been personally concerned where the plea of insanity was raised by the accused; he believed that it would be better to do away with any distinct and rigid definition of what constituted responsibility in these cases. No fresh shibboleths were needed, each case should be tried on its merits, and the defence should prove to the satisfaction of the jury (a) that the prisoner was suffering from a mental disease, and (b) that the crime was the outcome of such disease. There was no doubt that alienists recognized that there were degrees of responsibility, and he for one had long urged that English law should copy that of other lands and recognize degrees of the crime of murder. Some judges had made statements to the jury to the effect that the occupants of the jury box were quite as capable of gauging the prisoner's mentality as were the alienists who had given evidence. This implied that the man in the street knew quite as much about mental disease and all its ramifications as did those medical men who had devoted their lives to the study of the insane mind, who had lived with the insane, summered and wintered them. This Dr. Weatherly described as unfair, untrue, and illogical.

The PRESIDENT said that medical men were not always at one on the initial question whether there was or was not mental disease, but he strongly adhered to the recommendation of the committee over which he himself had presided that if the accused committed crime under an uncontrollable impulse by reason of mental disease, he ought not to be held legally responsible.

Other speakers were Messrs. BARRY O'BRIEN, T. SIMPSON PEDLER, and C. PILLEY, and Drs. T. B. HYSLOP, CRESWELL, and FINUCANE.

#### *Proposed Central Medico-Legal Institute.*

Lord JUSTICE ATKIN announced that the council of the society was considering the establishment in London of a central medico-legal institute for England and Wales, and a committee had been formed with Sir Bernard Spilbury as secretary, and Sir William Wilcock, and Messrs. Danford Thomas, Roland Burrows, and Webster, as members. The general idea was to establish a central institute where research work could be carried on, pathological inquiries made, and medico-legal experts brought together for the purpose of assisting in the solution of problems, especially in relation to crime. It was possible, with the help of the hospitals who thought it desirable to enter into the scheme, that medico-legal teaching would be available under highly trained teachers. A meeting for discussion of the whole subject would be held on Tuesday, June 23rd.

A MEETING of the London Association of the Medical Women's Federation was held on May 8th at the London School of Medicine to entertain the council members of the federation; demonstrations were given by various members of the staff of the school. Professor WINIFRED CULLIS demonstrated the action of certain drugs on the isolated mammalian heart, and the production of arrhythmia by section of the *a-v* bundle. Miss M. BOND, M.Sc., communicated the results of her investigations into the content of vitamin A in bacon fat, which is largely used in the dietary of children. Miss D. WOODMAN showed slides indicating that feeding rats with parathyroid inhibits thyroid action. Dr. PHILMAN WILLIAMS demonstrated the methods of blood group determinations. Microscopic preparations of foetal tissues were exhibited by Professor M. F. LUCAS KEENE and Dr. E. E. HEWER to illustrate some points regarding the correlation between the structural changes in the

organs of the foetus with physiological activity. Miss M. WALLER demonstrated emotive response to stimulation. A demonstration was given by the National Institute of Industrial Psychology of various psychological tests. Examples of the best known varieties of linguistic and performance intelligence tests were given, and general tests for "manual dexterity" and "mechanical ability" in connexion with vocational guidance. Some tests which are being used for vocational guidance and selection were illustrated, and also tests employed in the selection of engineers, weavers, clerks, and packers; these tests had been devised by the institute at the request of industrial firms.

## Reviews.

### TWO HANDBOOKS OF OBSTETRICS.

THE sixth edition of Dr. EDELL's well known and standard *Manual of Midwifery* has been brought out by Dr. EDDLE HOLLAND, who is responsible for the changes made in it. These are conveniently summarized by him in the preface. Perhaps the most important are the rewriting of the section on the toxæmias of pregnancy, the addition of a new section on diseases, injuries, and death of the foetus, and of another short new section dealing with the statistics of the maternal mortality of childbirth.

The section on toxæmias shows a thoroughly judicial weighing of the present views upon this complex subject. Dr. Holland, not unnaturally, leans to the placental theory of causation, but perhaps he discards too completely—on laboratory evidence—the possibility of a metabolic auto-intoxication as at any rate a possible predisposing factor.

The space given to the time-honoured teaching of the mechanism of labour is comparatively scant. It is rather the fashion of the moment to make less of this than was done in the teaching of a previous generation, and from the point of view of the instruction of the student we are disposed to think the change is not for the better. The anterior and posterior rotation of the occiput in occipito-posterior positions is dealt with in a way that is scientifically quite logical, but the result is calculated to be confusing to the student, as it lacks unity or continuity. We cannot agree with the editor's advocacy of version in preference to manual rotation in persistent occipito-posterior cases in multiparæ with the head above the brim; no reference is made to rotation by forceps, which, although admittedly more risky to the foetus than manual rotation, is yet in careful hands a most valuable method of delivery, and one which deserves serious discussion in any textbook of this standing. The section on breech cases is good, and we are glad to find emphasis laid on the value of preliminary perineotomy in primiparous breech cases. Of scopolamine-morphine narcosis the editor is apparently but a tepid advocate, and he makes no reference to quinine (and a fortiori none to glucose) as a uterine stimulant in labour.

Placenta prævia and accidental hæmorrhage are discussed in a way which brings out their common factors clearly. This is in keeping with modern research, even if it does not make their study easier for the student. The section dealing with the infant and its injuries and diseases is admirable, as might be expected from one who has devoted so much study to the subject. The pleas for the recognition of pulmonary respiration as the sign of "livebirth"; for the use of the term "deadbirth" where the foetus dies without breathing, even although its heart is beating at birth; and the use of the term "stillbirth" as synonymous with "asphyxia neonatorum," are sound, and it is to be hoped that medical writers, and especially medical jurists, will adopt these definitions. In the operative section we are glad to see that the methods of accouchement forcé are dismissed in a paragraph as operations "of great gravity, in comparison to which Cæsarean section is simpler, safer, equally expeditious, and applicable to all conditions." The description of the operation of Cæsarean section is very clear, but it seems out of place to devote five pages to

<sup>1</sup> *A Manual of Midwifery*. By Thomas Watts Edell, M.D., C.M. Edin., F.R.C.P. Lond., F.R.C.S. Edin., and Eardley Holland, M.D., B.S. Lond., F.R.C.P. Lond., F.R.C.S. Eng. Sixth edition. London: J. and A. Churchill 1925. (Demy 8vo, pp. xii + 704; 393 figures, 7 plates, 21s. net.)

pubiotomy and symphysiotomy, which for the second time in their history are nearly obsolete procedures.

We congratulate the authors most cordially on a very excellent volume, which gives an admirable representation of the present position of obstetric science in this country. In our view Dr. Holland has made the book rather more of a practitioner's and rather less of a student's textbook, but, that criticism apart, he has distinctly enriched an already valued and tried guide to midwifery.

Dr. HASTINGS TWEEDIE'S *Practical Obstetrics* has for some years had a definite place in the obstetrical literature of this country, and the call for a fifth edition<sup>2</sup> since 1908 is evidence of this. It is regrettable to learn from the preface that a serious defect in Dr. Tweedie's sight has considerably handicapped him, but he is to be congratulated on having secured the collaboration, not only of Dr. G. T. WRENCH, who was jointly responsible with him for one or two of the previous editions, but also of Dr. BERNEL SOLOMONS, who, as a teacher and consultant, is thoroughly familiar with the latest changes in the views upon matters obstetrical. With regard to the subject-matter of the volume, nothing need be said except that this edition fully maintains the high standard previously set. The appendix again contains a valuable series of statistics based upon the experience of the Rotunda Hospital. There is also an appendix expounding Stroganoff's treatment of eclampsia, and a short article giving Dr. Tweedie's personal and rather uncommon views as to the origin of the lower uterine segment. So far as our recollection serves, these were all in the last edition, and the two latter articles might, one would think, have been incorporated in the body of the book—always provided the author thinks them suitable.

The last appendix is entitled "Haemorrhagic shock," and deals with the exceedingly interesting subject of the profound shock associated with comparatively small internal haemorrhages in concealed accidental haemorrhage and ruptured tubal pregnancy, etc. Dr. Hastings Tweedie's views have always been strongly individualistic, and as such both welcome and refreshing. But in this article his reasoning seems to be questionable and to require support from much more in the way of carefully observed facts than are provided, before it can be accepted. For its acceptance would, as the author cheerfully points out, involve the scrapping of the universally accepted teaching as to the danger of extracting a child from an inert uterus. Revolutionary and subversive teaching of this sort requires to be justified up to the hilt before it can be accepted, and it is interesting to notice that Dr. Tweedie or his collaborators very wisely adhere to the traditional teaching on this matter in the chapter on uterine inertia. Dr. Tweedie attempts to forestall criticism on his views in the form of "unsupported expressions of opinion," while welcoming further "facts and logical deductions." Certainly these latter are needed, but the author cannot in this way and by his own statement place himself beyond the range of legitimate criticism; and we must respectfully express considerable scepticism.

#### DIAGNOSIS AND TREATMENT OF SYPHILIS.

THE discovery of the causal organism of syphilis, the development of a satisfactory laboratory method for the diagnosis of the disease, and the elaboration of a chemical preparation for its treatment, together formed an enormous contribution to scientific and practical medicine. None of these three great advances was sudden: the way was prepared for each. All of them in turn formed the starting point of further research.

The monograph by BROWNING and MACKENZIE entitled *Recent Methods in the Diagnosis and Treatment of Syphilis*, which has now reached a second edition<sup>3</sup> and has

<sup>1</sup> *Practical Obstetrics*. By E. Hastings Tweedie, M.D. (Honoris Causa), F.R.C.P.I., and G. T. Wrench, M.D., in collaboration with Bernel Solomons, M.D., F.R.C.P.I. Fifth edition. Oxford Medical Publications, London: Humphrey Milford, Oxford University Press, 1925. (Demy Bro, pp. xvi + 617; 124 figures, 21s. net.)

<sup>2</sup> *Recent Methods in the Diagnosis and Treatment of Syphilis*. By Carl H. Browning, M.D., D.P.H., and Ivy Mackenzie, M.A., B.Sc., M.D. With an Introduction by Robert Muir, M.A., M.D., F.R.S. Second edition. London: Constable and Co., Ltd. 1924. (Demy Bro, pp. xxii + 537; 5 plates, 42s. net.)

been so extensively rewritten as to constitute a new work, is the only book we have that leads the student through all these varied researches. So voluminous is the literature on the mechanism of the Wassermann reaction alone that few can claim to be conversant with the major part of it. Useful as this reaction has proved in clinical practice, its underlying principles are not wholly understood, and if reliance is to be placed upon it we must have an appreciation of the extent to which each factor in the reaction varies and the methods by which the variations can be controlled. Professor Browning has omitted no contribution of any consequence, and this alone, quite apart from his own researches and the critical judgement he has brought to bear on the numerous problems, makes the book invaluable to other laboratory workers in all that pertains to serology. His association, too, with Ehrlich in the investigations that led to the development of salvarsan makes him an able guide in the exposition of the chemotherapeutic researches.

The first four chapters are devoted to a consideration of the *Spirochaeta pallida*, its characteristics, its pathogenic properties and biology, and the tissue changes it produces. In eight chapters each separate constituent of the Wassermann reaction is extensively studied. The immense amount of work and experiment that this has entailed will be appreciated by everybody, and fellow workers will find these chapters a mine of information. The flocculation reactions, the examination of the cerebro-spinal fluid (ably written by Dr. J. Cruickshank), and the clinical application of the investigations, form other chapters which for thoroughness, critical judgement, original observation, and intelligible presentation, could not well be surpassed. Dr. Mackenzie is responsible for the clinical section, and gives a general survey of the results of treatment.

Mainly intended for pathologists, the book will not be unwelcome to the practitioner who desires to be conversant with the scientific basis on which modern diagnosis and treatment are built.

#### ATLAS OF URINARY CALCULI.

PROFESSOR NAKANO of the University of Tokyo has produced a fine atlas of urinary calculi.<sup>4</sup> The figures, based on nearly four hundred in number, have been selected from more than six hundred specimens, and are comprised in thirty plates, most of which are executed in colour photography. The process lends itself admirably to the representation of calculi, their external form, colouring, and detail in section being depicted with very close approximation to the natural appearance. The main incentive to the production of the atlas appears to have been a desire on Professor Nakano's part to ascertain the process of formation of urinary calculi, and for six years he devoted himself to this study, partly by experiment, and partly by the examination of microscopic sections of calculi. Of the latter he has studied no fewer than a hundred and forty, varying in thickness from 5 to 20 microns. In this way he has investigated the action of polarized light, the crystalline form and mode of deposit of the crystals; further, the nature of the radial and concentric striations, and the origin of fissures, or spontaneous fractures so called. He has also undertaken a quantitative and qualitative chemical analysis of nearly six hundred calculi and estimated their organic constituent. Details of these investigations are given in the text. The author has made a special point of comparing the process of formation of urinary calculi with that occurring in ordinary mineral deposits; he finds many analogies between the two and is inclined to regard them as practically identical. His conclusions as to the origin of calculi are that the organic constituent is not essential to their formation but is a secondary product arising from contamination with albuminous matter, thus opposing the view of Ebslein, who held that no urinary stone could be produced without some organic substance; further, that a calculus may form in perfectly normal urine; and that there must be a definite nucleus possessing irregularities of surface or other qualities which would allow of a deposit occurring around it. With

<sup>4</sup> *Atlas der Harnsteine*. Von Dr. H. Nakano. Mit einem Geleitwort von Professor Dr. V. Blum. Leipzig und Wien: Franz Deuticke, 1925. (Med. 4to, pp. xvi + 25; Atlas pp. 45; 364 figures, 30 plates, Grundzahl 307)

regard to the albuminous matter, it is admitted that its presence favours the formation of a calculus by promoting adhesion between the inorganic particles. As an example of the formation of a calculus in normal urino, the author mentions the case of vesico-vaginal fistula in which a stone formed round a partly separated suture, the urino being perfectly normal. To show that some foreign bodies may not serve as nuclei, a case under Professor V. Blum is quoted, in which a metallic fragment had remained in the bladder for three months without becoming encrusted and without producing any ill effect beyond slight catarrhal cystitis.

### NOTES ON BOOKS.

In our issue of July 19th, 1924, Professor R. T. Lelper drew attention to the unsatisfactory treatment of parasitology in the various standard public health textbooks. It is unfortunate that the author of the latest publication on *Parasitology for Medical Students* should not have thoroughly digested that article before he wrote his book. Its scope is wide, for the arthropods, helminths, protozoa, and fungi are considered in some 140 pages, but the treatment is inadequate; many of the statements are misleading, some are inaccurate, and others are confusing. Thus, for example, the term "bug" is used in a loose manner; and the reader might be led to suppose that the bed-bug is the normal carrier of South American trypanosomiasis. In the helminth section, the author might lead the reader to believe that "brood capsules" and "daughter cysts" in hydatids are the same thing; and that the diagnosis of alveolar hydatid infection is normally made by finding segments in the stool. There is a lack of proportion in the selection of the various parasites for discussion. For example, the proface states that the work will deal with parasites of practical importance from the point of view of the physician; yet two pages are devoted to the consideration of *Trichostrongylus axei*, which is a very rare human parasite, only infecting man by accident, while much more important human flukes are ignored. The illustrations in half-tone are poor and of little or no value to the student. Those of the helminth eggs are especially unsatisfactory; and surely the male *Ancylostoma duodenale* depicted on page 83 is a neater? The terminology is mixed. In some cases the correct name is given; in others, it quoted at all, it is given as a synonym. We fear it must be said that the book falls below the standard attained by others in the series of the Oxford Medical Publications.

The twenty-seventh edition (the thirteenth for publication) of *Rules for Compositors and Readers* has appeared. The rules laid down in this little book were originally intended for the use and guidance of compositors and readers at the Clarendon Press, Oxford. After a while copies found their way into the hands of authors and editors of books and periodicals, and readers and compositors in other printing offices began to ask for copies. These were supplied free of charge. By and by applications were made by persons other than those for whom the book was intended, but as many of these held positions under Government (either at home or abroad) the practice of presentation was continued. Then it became known that copies were on sale in London, and it was felt that there was no alternative but to publish the book. The fact that it has run through so many editions is proof of its usefulness, not only to those for whom it was originally compiled, but to all engaged in literary work. From time to time additions and slight alterations have been made in the *Rules*. Those in the twenty-seventh edition include a large number of medical terms and the recommendations of the Society for Pure English as to the printing of foreign words in common use in this country. We are more particularly interested in the list of spellings for use in medical works (pp. 25-32), and, though perhaps not altogether content with the arrangement of the "Words with Hyphens" and "Words without Hyphens," believe that this list will be of value to those engaged in preparing medical books for publication, and hope that its circulation may tend to eliminate the atrocities too often met with in the lay press. It is not altogether easy to follow the lines laid down for the use or omission of the hyphen. Why (to take only an example or two among many) should "cardio-gastric" and "cervico-dorsal" be printed with a hyphen, and "glossopharyngeal"

and "sternooclavicular" without? Many of the terms would be better expressed as two words—an "heart sound," "bile passages," "blood content," "blood volume," to mention only a few. The list seems to be remarkably free from actual errors; there are, however, a few terms we do not remember having seen before—an, for example, "hydrogenotransportases," "naphthylamine," and "mobillinogenuria"; it is to be hoped that the too conscientious compositor or reader will not substitute this last term for "urobilinuria," which is not in the list. We suspect that the last word on page 31—"sensorimotor"—should be "sensorimotor"; vitamin appears with a final e. The list, though not very comprehensive, is likely to be of value to those printers who have only an occasional medical work to produce, and whose readers would be lost without a guide to terms rarely met with in general work. The new edition of the *Rules* has apparently been revised under the direction of "F. J. H."—the initials, we assume, of the present printer to the University of Oxford—who is to be congratulated on its appearance.

The volume on *Pediatrics*, edited by Dr. ISAAC A. AIT with the collaboration of Dr. JOHANNES HEUMANN, forms part of the "Practical Medicine Series," which consists of eight books issued at various intervals during each year under the general editorship of Dr. CHARLES L. MIX. The present volume, which, as we learn from the introduction, has for more than twenty years shared its pages with orthopaedics, now appears for the first time as a separate volume devoted exclusively to pediatrics. The book contains an excellent summary of the world's work in the medical diseases of children, accompanied by judicious editorial comments; it should prove a useful guide.

The second instalment (Caja-Gestügel) of the lexicon of nutrition, edited by Professors E. MAYERHOFFER and CLEMENS PIQUET, of which the first part was noticed by us last year (JOURNAL, February 9th, 1924, p. 242), has recently been published. The subjects discussed include among others Carême (the celebrated Parisian gastronomist), Chinese nutrition, diabetic diet, eggs, fever diet, Finkelstein's scheme of nutritional disorders in the infant, fish, meat (Fleisch), and fowl. The work will appeal to all who take a scientific interest in food problems.

Ait, M.D., with the collaboration of Johannes Heumann, M.D. Series 1924. Chicago: The Year Book Publishers. 1925. (Cr. 8vo, pp. 331; 27 plates. 2 dollars.)

<sup>2</sup> *Lexikon der Ernährungskunde*. Herausgegeben von Dr. E. Mayerhofer und Dr. C. Piquet. 2. Lieferung. Wien: Julius Springer. 1925. (Sup. roy. 8vo, pp. 191. G.M.7.)

### MEDICAL AND SURGICAL APPLIANCES.

Dr. R. J. ASSALINI, of New York, has designed a modification of the Assalini instrument, and claims that it retains the good points possessed by the original Assalini instrument, one of which is its adaptability to the modification proposed, and possesses the additional advantage presented by the backward curve of the handles, by which the forceps are given an axis-traction effect in the simplest possible manner, and without any additional apparatus in the form of traction rods, etc. As traction is applied to the extreme end of the handles the full value of the backward curve is obtained.

The good points already possessed by the original Assalini instrument appeal chiefly to the general practitioner, who conducts his confinements with his patient in bed, and not on an operating table. Difficulty is encountered in passing the upper

blade with the lower one already in place, until by experience a better method than is taught to students has been learnt. With Assalini forceps there need be no difficulty with the upper blade, which is passed first horizontally in front of the sacrum and then rotated carefully into its proper position. The nurse can then hold it well back while the lower blade is passed into place. This manoeuvre is not impossible with ordinary forceps, but to make it easy the lock should be reversed.

There is one more advantage which is quite important. The ordinary pattern of forceps can have, in the hands of a vigorous obstetrician, some of the qualities of a cephalotribe. This is undesirable and is avoided by the Assalini instrument.

Messrs. Arnold and Sons (John Bell and Croymond, Ltd.), 50-52, Wigmore Street, London, W.1, are the makers.

<sup>3</sup> *Parasitology for Medical Students*. By Alex. Mills Kennedy, M.D. Glas. Oxford Medical Publications. London: Humphrey Milford, Oxford University Press, 1925. (Demy 8vo, pp. x + 142; one coloured plate; 61 figures. 10s. 6d. net.)

<sup>4</sup> *Rules for Compositors and Readers at the University Press, Oxford*. By Horace Hart, M.A. The English spelling revised by Sir James A. H. Murray, M.A., D.C.L., D.Litt., and Henry Bradley, M.A., Ph.D. Twenty-seventh edition (the thirteenth for publication). London: Humphrey Milford. 1925. (32 x 54, pp. 133. 2s. net.)

# NINETY-THIRD ANNUAL MEETING of the British Medical Association, BATH, 1925.

City wall opposite Mineral Water Hospital. (From a wood engraving by Horace Gerrard.)

Most of our readers are by now aware, the ninety-third Annual Meeting of the British Medical Association will be held at Bath at the close of July, under the presidency of Dr. F. G. Thomson, physician to the Royal United Hospital, Bath, and consulting physician to the Royal Mineral Water Hospital. The Annual Representative Meeting, for transaction of medico-political business and discussion of the internal affairs of the Association, will open at Bath on Friday, July 17th. The statutory Annual General Meeting will be held on the afternoon of Tuesday, July 21st, and on the evening of the same day the new President will deliver his Address to the Association. The twelve Sections, among which the scientific and clinical work of the meeting is being divided this year, will meet on the three following days. The full list of Sections and sectional officers, together with the provisional programme for the Bath Meeting, were published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of April 11th, 1925. Further details of the arrangements will appear in later issues. On the last day of the meeting, Saturday, July 25th, there will be excursions to places of interest in the neighbouring West Country. We publish below the second of a series of descriptive and historical articles on Bath.

## THE MEDICAL INSTITUTIONS OF BATH.

NOTES BY

JOHN HATTON,

DIRECTOR OF THE HOT MINERAL BATHS.

In this article are given some brief notes on the Medical Institutions of Bath. Although Bath will not be able to show her guests the vast hospitals, with all their elaborate equipment, which they may have seen in some of the great cities visited by the Association in previous years, Bath possesses medical institutions of unusual character which, it is hoped, will not be without their special interest.

### THE ROYAL MINERAL WATER HOSPITAL.

The Royal Mineral Water Hospital will no doubt, by reason of its special character, be the most interesting of the hospitals of Bath. It is in no way a local institution, in the sense of providing for the needs of local patients, but a national hospital for the treatment of rheumatic diseases, established for the purpose of bringing the benefits of the Bath mineral waters within the reach of those who, without some such help, would never be able to obtain the specialized treatment a spa affords.

In the words of the Act of Parliament under which the hospital was incorporated in 1739,

"Any person resident in and belonging to Great Britain or Ireland, whose circumstances are such that they are not able to have the benefit of the Bath Waters without charitable relief, are entitled, and have a right, to the relief of the Hospital."

So strongly was it held that the hospital was provided for the relief of sufferers from rheumatic diseases throughout the country that four years later it was actually decided that the inhabitants of the city of Bath were not eligible for admission, and for nearly a hundred years the local poor were excluded from the benefits of the charity. The hospital draws its patients from every part of Britain, and even now it is the exception to find amongst them any Bath residents. Patients are admitted without any subscriber's recommendation, and it is only necessary to satisfy the Governors that the person desiring admission is unable to afford the expense of obtaining the treatment otherwise and that the case is one in which the use of the mineral waters is applicable. Patients whose means allow are now, of course, expected to contribute something towards their maintenance.

It is, as one would expect, during that long period when the springs were under the control of the Church, that we find the earliest records of the charitable use of the waters. Bishop Robert, in 1138, founded a hospital for lepers, attaching to it a bath called the Lepers', or Lazours', Bath, which actually existed until the eighteenth century.

But the present hospital may rather be looked upon as the successor of an Act of Queen Elizabeth, dated 1597, which gave to the diseased and impotent poor of England a right to the free use of the baths of Bath, and empowered the justices of the peace in any county to license such persons to travel to Bath, there to be cured of their ailments. The natural result followed, and as Fuller records in his *Worthices*,

"Many were in that place; some natives there; others repairing thither from all parts of the land, the poor for alms, the pained for ease. Where should fowl flock, in a hard frost, but to the barn door?—here, all the two seasons, being the general confluence of the gentry. Indeed laws are daily made to restrain beggars and daily broken by the connivance of those who make them, it being impossible when the hungry belly barks and howls around to keep the tongue silent. And although oil of whip be the proper plaster for the cramp of laziness, yet some pity is due to impotent persons."

Among the impostors were many genuine sufferers, and in 1716 a movement was started to establish a hospital for their relief. For some time progress was slow, but in 1738 the foundation stone of the new hospital was laid by the Hon. William Pulteney, afterwards Earl of Bath.

Beau Nash threw himself with all his energy into the effort of raising funds, collecting personally more than £2,000 (no small sum in a period which knew neither Lord Knutsford nor Lord Mildmay of Mele). Forty guineas were wiled out of the Duchess of Queensberry at the card table, Nash assuring the reluctant old lady that "Charity hides a multitude of sins." Dr. Oliver was assiduous in his support, Ralph Allen gave the stone from his famous Bath stone quarries, John Wood, the architect, then at the height of his fame, presented the plaques, and other notable people of the day gave freely of their time and talents to the promotion of the scheme.

The hospital is proud to have H.M. the King as its Patron, and as its Vice-Patron H.R.H. the Prince of Wales, who visited the hospital in 1923, and last year held the office of President, the third Prince of Wales to occupy that chair.

Originally the hospital contained only night wards, and accommodated, by overcrowding, rather more than a hundred patients at a time. Subsequent extensions provided spacious day wards, and increased the capacity to its present figure of 136.

The hospital has its own suite of baths supplied by the Corporation with mineral water from the hot springs, the hydrological treatments provided including Aix and Vichy douches, Scottish and needle douches, whirlpool baths, reclining and vapour baths, and the deep pool bath. Radiant heat and various forms of electrotherapy, massage, and remedial movements, by machines of the Zander type, are also employed.

Since its foundation the hospital has treated 104,600 patients. During each year about a thousand cases pass through the wards. The number for the quinquennial period 1920 to 1924 was 5,904, of whom 93 per cent. were discharged as "cured or relieved."

The Mineral Water Hospital has always shown a warm interest in wounded and invalided soldiers. Early in 1747 the Governors made special arrangements for the admission of those who had been maimed or wounded "in the recent rebellion in Scotland." During the Crimean war several soldiers were admitted at the request of the Director-General of the Army Medical Department, who wished to try the efficacy of the mineral waters in the treatment of diseases brought about by active service, and the hospital records show that 75 per cent. were discharged as "recovered or benefited." During the South African war twenty beds were placed at the disposal of the War Office, and 112 men were treated, Lloyd's Patriotic Fund making a grant of £50 to the hospital in recognition of the benefits these men derived.

At the outset of the great war the Governors offered the whole accommodation to the War Office for the use of soldiers, but in acknowledging the offer the Secretary of State considered that the regular work of the hospital should, as far as possible, be maintained. The army medical authorities were, however, glad to make use of the special facilities the hospital provided, and during the war, and in the period immediately following, 4,968 sailors and soldiers were admitted. Most of them were benefited, and many were enabled to resume active service. A limited number of Belgian soldiers were received. On arrival many of these could hardly move hand or foot, but they improved rapidly, and many returned to duty.

In 1914 a new Pathological Laboratory was opened by Sir William Osler, who drew particular attention to the large field provided for research in the cases passing through a specialized hospital such as this. On his recommendation a medical library was established in connexion with the laboratory.

Generous supporters, notably the present Mayor, Alderman Cedric Chivers, have enabled important investigations to be carried out, and work has been done, especially in connexion with the various classes of fibrositic and arthritic (including gouty) patients, who form the majority of admissions. These include some hundreds of blood counts, a systematic investigation of the behaviour of blood serum towards streptococcal antigens in complement fixation tests; basal metabolism, vital capacity, blood contents of glucose, creatinin, uric acid and calcium, glucose tolerance and urea concentration, and other biochemical features. Work has also been done on calcium metabolism in cases of osteo-arthritis and spondylitis.

Thus, in the research work of to-day the hospital is very definitely fulfilling one of the objects of its promoters. For in the original advertisement of the hospital in 1737 it is pointed out that by collecting these rheumatic cases in a hospital—

"It would give the Physician a sufficient opportunity either of doing them all the service their case would admit of or of making observations for the future benefit of others. A few years will furnish more Histories of Cases, which may be depended on, than any Man's private practice would have done in an Age."

### THE ROYAL UNITED HOSPITAL.

In its present form the general hospital of Bath—the Royal United Hospital—dates from 1826, when the central block was opened, but, as its name indicates, the hospital represents the union of two old charities, the Bath Pauper Charity, founded in 1747, and the Casualty Hospital, which was opened at 38, King's Mend Street, on January 1st, 1788. At one period of its history the older institution, under the title of the Bath City Infirmary and Asylum, was located in the residence formerly occupied by Dr. Samuel Bave, a native of Cologne, who practised in Bath for thirty years and died in 1668.

In 1864 the Albert Wing was built in memory of H.R.H. Prince Albert, another story, called the Prince of Wales Ward, being added to this wing in 1891 to provide accommodation for children. In 1914 the hospital was further improved by the reconstruction of the out-patient department and the provision of

x-ray and other modern departments. At the present time the old x-ray apparatus is being replaced by an entirely new installation.

The hospital, which has 140 beds and averages over 8,000 cases a year, draws its patients not only from Bath, but from an extensive area comprised within a radius of some twenty miles of the city, embracing the mining district around Radstock, the Bath stone quarries of Box and Corsham, the woollen factories of Trowbridge, and the rubberworks of Bradford-on-Avon. Last year (1924) 2,224 in-patients were admitted, 83 patients were visited at their own homes, and 5,849 out-patients were treated—a total of 8,156. During the year there were 1,594 operations.

The hospital occupies a position in the centre of the city which does not allow of any further extension, and the only practicable solution of the problem of meeting increasing demands will be removal to a less congested site.

Like all similar institutions, the Royal United Hospital has had its financial embarrassments, and a couple of years ago the situation was very serious. The friendly societies of the city then devised a scheme of collecting boxes combined with a pledge of a weekly contribution of not less than twopence. Taken up readily in the city and the surrounding districts, exceptionally well organized and worked with enthusiasm by the energetic members of the friendly societies, the scheme is yielding an annual income of £5,000 which shows every sign of being maintained.

The hospital has ever been fortunate in its honorary medical staff, but there will be no disparagement of other good men in saying that the name of Caleb Hillier Parry, physician to the Casualty Hospital from 1800 to 1817, stands pre-eminent. Best known to the profession at large for his work in connexion with exophthalmic goitre—which is Parry's just as much as it is Graves's disease—he has left in his published writings and in the notebooks, which are carefully preserved in the library of this hospital, the record of a scientific mind, assiduous in seeking knowledge from personal observation, sound in judgement and gifted with unusual powers of deduction. That these gifts were combined with, or rather found

ROYAL MINERAL WATER HOSPITAL.  
(From a wood engraving by Horace Gerrard.)

their fullest expression in, sound therapeutics is shown by his extensive practice and the wide fame enjoyed by this distinguished Bath physician.

#### THE FORBES FRASER HOSPITAL.

This, together with the Children's Orthopaedic Hospital described below, is the latest addition to the medical institutions of Bath. It was opened by H.R.H. the Duke of Connaught on May 16th, 1924, while that great surgeon and lovable man after whom it was afterwards named was still lying ill.

The Forbes Fraser Hospital forms the beginning of a big scheme formulated by the late Mr. Forbes Fraser, F.R.C.S., in 1920, for the eventual removal of the whole of the Royal United Hospital to the outskirts of the city, where extensions could be carried out on an open site, leaving a casualty station only in the central area, with possibly an out-patient department. In particular, paying wards were to be provided for persons of limited means. This scheme was adopted by the Managing Board and a site of twenty-one acres was purchased at Combe Park, upon which, in 1915, the Bath War Hospital had been built. A portion of the land was leased to the Ministry of Pensions, which had taken over the existing War Hospital, still maintained as a pensions hospital for the South-Western area.

The Forbes Fraser Hospital for paying patients enjoys to the full the advantages of beautiful surroundings and an open airy situation. It is a one-story building of the bungalow type, designed by Mr. Alfred J. Taylor, F.R.I.B.A., and planned in two wings, containing twenty-four private rooms and four wards of twelve beds each, curtained off into cubicles—a total of seventy-two beds in all. There are sun balconies in front of the private rooms and at the end of the wards.

In the central administration block are the medical officer's and matron's quarters, two operating-theatres, kitchen, and store-rooms. A separate building contains the power block, the boiler-house for the hot-water supply, and electric light plant and the laundry.

The fees are £5 5s. a week for a private room and £3 3s. for a bed in one of the wards. In maternity cases the present charge for a private room is £6 6s. weekly. These fees do not include surgeon's or medical practitioner's fees, but entitle a patient to board, nursing, ordinary medicine, and surgical dressings. Additional charges are made for special nurses, massage, special diets, expensive remedies, x-ray or other special investigations. In operation cases a theatre fee of 1 guinea is charged for minor operations and 2 guineas for major operations.

The treatment of patients is not confined to the staff of the Royal United Hospital, but is open to all registered practitioners, the only restriction being that no major operation may be performed in the hospital except by a present or past member of the surgical staff of a recognized general or special hospital.

It is believed that this is the first hospital in the country built solely for the accommodation of patients of moderate means, and it is already proving its value. The committee, under the chairmanship of Sir Percy Stothert, K.B.E., has been fortunate in securing several handsome donations, including one of £5,000 from Mr. Stanley Wills, which have enabled a start to be made on the useful addition of a nurses' home on a piece of ground of four acres presented by the Mayor of Bath.

#### CHILDREN'S ORTHOPAEDIC HOSPITAL.

It is to the late Mr. Forbes Fraser, Alderman Cedric Chivers (who, as Mayor of Bath, will welcome the British Medical Association to the city next July), and Mr. Walter E. Mallett, the chairman of the Children's Orthopaedic Hospital, that Bath owes this valuable institution. The hospital is intended to serve Bath and the counties of Somerset and Wiltshire.

On a portion of the Combe Park site, providing the essential conditions of sunshine and space, an open-air hospital has been planned containing at present thirty-seven beds and capable of extension. Children up to the age of 16 are eligible for admission, and the organization provides all essentials for treatment, such as the supply of appliances, equipment for surgical operations, massage and other forms of physiotherapy, and investigations by x-ray and laboratory methods. In accordance with the requirements of the Board of Education, a qualified schoolmistress has been engaged to carry on the education of the children while in the hospital.

An important part of the scheme is the after-care of the patients. With this object local orthopaedic clinics are being established at suitable subcentres throughout the area to

secure the periodical inspection of old cases, provide out-patient treatment, and afford facilities for examination and diagnosis of new cases. Each clinic will be controlled by a local committee in co-operation with local doctors, and a specially trained after-care sister from the central hospital will visit regularly.

#### BATH EYE INFIRMARY.

Founded in 1811, the Bath Eye Infirmary is one of the oldest provincial institutions of its kind. From small beginnings the hospital gradually grew, moving several times to fresh premises as the work expanded, until it settled in the present building in Belvedere in 1899. The accommodation again proved to be insufficient, and the adjoining house was purchased in 1905 and added to the institution.

The hospital now contains twenty-one beds and one cot. Patients are drawn from a large area—Somerset, Wiltshire, and part of Gloucestershire. Out-patients are treated gratuitously; in-patients are admitted on subscriber's recommendation. The infirmary also treats children attending the schools of the education authority who are sent to the institution through the school clinic.

During 1923, 214 in-patients were admitted, and 2,203 new out-patients. The number of old out-patient attendances was 3,074, an increase in numbers over the previous year. Financial support has always been forthcoming, and although low been experienced the hospital is having been in debt since its foundation over 113 years ago.

#### BATH EAR, NOSE, AND THROAT HOSPITAL.

The Bath Ear, Nose, and Throat Hospital, the only one in a very large area of the South-West, was founded in the year 1837 in the Walcot district of Bath, under the title of the Bath Ear and Eye Infirmary. The work of the hospital was, however, largely confined to laryngology, otology, and rhinology, from the first, and the eye work was handed over to the Bath Eye Infirmary at an early date.

In the year 1914 the hospital was transferred to larger premises in Charles Street, where the work was carried on during the period of the war. At this time the hospital was used for the training of personnel of the 2nd and 3rd Bath Units of the R.A.M.C., known as the South-Western Mounted Brigade Field Ambulance, in hospital duties and the special work connected with ear, nose, and throat.

In 1920 it was found that the Charles Street building was inadequate to cope with the work amongst the civil population, to which was added a large number of soldiers and pensioners

ROYAL UNITED HOSPITAL.

JUNE 6, 1925]

# MEDICAL INSTITUTIONS OF BATH

THE PASTOR  
MEDICAL JOURNAL

1045

who, till the establishment of the special department at the Bath Pensions Hospital, came to the institution for treatment. The hospital was accordingly moved to its present position in Marlborough Buildings, the Board of Management acquiring the war-time officers' hospital, commanding an extensive and delightful view over the Royal Victoria Park. Fifty beds and cots were equipped in these premises, the hospital thus constituting one of the largest, as well as almost the oldest, ear, nose, and throat hospital in the country. Patients are drawn not only from Bath, but from a large area including many surrounding counties. The number of operations performed during the past year was over 500. In-patients numbered 427, and the attendance in the out-patient department was over 4,500.

## BELLOTT'S HOSPITAL.

Founded in 1610 by that Thomas Bellott, Lord Burleigh's steward, a munificent benefactor alike of the Abbey and the city of Bath, of whom it was written—

"Hospitals, baths, streets and highways  
Sound out the noble Bellott's praise,"

this small hospital for poor patients who resort to Bath for the benefit of the waters is now administered by the Municipal Charity Trustees in conjunction with the annuity left by Lady Elizabeth Seadmore for a physician to advise poor strangers as to the use of the Bath waters. There is accommodation for ten patients, who are provided with separate bedrooms, with light and heating, medical attendance, and medicine, the use of the mineral waters, and an allowance of 2s. 4d. a week. Any extra cost of maintenance must be paid by the patients, who must also provide themselves with towels, change of linen, and proper apparel. The cost of maintenance generally amounts to from 15s. to 18s. a week, in addition to the said sum of 2s. 4d.

## CENTRAL LABORATORY.

By the joint efforts of the Corporation and the Royal United Hospital a central laboratory has recently been opened under the direction of an experienced pathologist. Here are carried out pathological investigations of all kinds—bacteriological, histological, chemical, etc. The service of the laboratory is available for all local practitioners.

## OTHER INSTITUTIONS.

**Bailbrook House.**—This typical Georgian mansion, dating back to 1791, with the comfort and quiet dignity of its period, is an old-established home for the care and treatment of ladies and gentlemen suffering from nervous and mental disorders, standing on one of the hills overlooking Bath, about two miles distant from the centre of the city, in twenty acres of well laid out and wooded private grounds. There is a special annexe for ladies, Brook Villa, with a separate garden. Attention is particularly given to the curative treatment of early cases.

**Kingsdown House at Box, near Bath,** is another private mental hospital, for the treatment of mental and nervous disorders.

**Lansdown Hospital.**—At this hospital, founded under the Jennings Trust to provide skilled nursing and accommodation for all classes, special treatment is given for rheumatic and allied diseases as well as for other cases. The institution is self-supporting, but there is a benevolent fund which is applied to the service of poor patients seeking admission.

**Combe Down Convalescent Home.**—Accommodation for ten men and ten women is provided by the convalescent home which stands on the high tableland of Combe Down, 520 feet above sea-level. The home is about four miles from the centre of the city, but easily accessible by the electric trams which pass the gates.

**Dispensaries.**—Three dispensaries, established in the early part of the nineteenth century, are still in use and provide much appreciated facilities for poor people. There is also a Medical Institution under the auspices of a joint committee of the members, which provides out-patient facilities for their members.

**Bath Homoeopathic Hospital.**—There is a small homoeopathic hospital for the treatment of the sick poor and for the training of nurses on homoeopathic principles.

## MUNICIPAL HEALTH SERVICE.

The annual reports of the medical officer of health indicate the varied activities of the Health Committee of the Bath City Council.

The estimated population of the city is 69,270. During 1924 the number of births was 931, being equivalent to an annual rate of 13.2, compared with 18.8 for England and Wales. The corrected death rate was 11.7 and the infantile mortality was 65 and the corresponding rates for England and Wales were 12.2 and 75 respectively.

## Maternity and Child Welfare.

The council's scheme for maternity and child welfare includes an ante-natal clinic, the supervision of midwives, a district midwifery service, a maternity home, a health visiting department, infant welfare centres, and the provision of milk to mothers and children. The work is carried on in conjunction with certain voluntary societies on a plan so devised as to

allow freedom of action on the part of the societies, with adequate control by the council of expenditure of money from the rates. The voluntary bodies concerned are the Bath Infant Welfare Association, with three branches in different districts, and the Bath District Nursing Institute.

**Ante-natal Clinic.**—An ante-natal clinic for giving advice to expectant mothers is held weekly at the Rivers Street Maternity Home. During 1924 there were fifty-one sessions, at which 184 new cases were seen by the medical officer. The four city midwives paid 1,229 visits to these mothers at their homes before the confinements, and attended in all 342 births.

**Maternity Home.**—This home was opened in 1917 with five beds. The nursing arrangements are carried out under the supervision of the matron of the Bath District Nursing Institute, subject to the control of a committee of the council and the general supervision of the medical officer of health. By a suitable financial adjustment with the Nursing Institute the whole of the deficit in the working expenses is borne by the city. During 1924, 100 cases were admitted to the home, and the average stay in days was 15.7.

**Infant Welfare Centres.**—Three centres have been established: one at Roswell House, where two consultation clinics are held every week, and one in each of the Walcot and Oldfield Park districts, at which one consultation clinic is held weekly. This work is carried out by the Bath Infant Welfare Association in conjunction with the staff of the Health Department.

**School Clinic.**—The school clinic is conducted at Roswell House by the Education Authority, and here all the usual facilities are provided, including an orthopaedic clinic.

**Tuberculosis.**—The administration of this is under the medical officer of health, but the actual clinical work is carried out by the Tuberculosis Dispensary at 26, Charles Street.

**The Statutory Fever Hospital.**—This hospital consists of three wooden blocks for patients, an administration block, a discharge block, and a laundry. It is situated on Claverton Down and stands in eight acres of ground.

## WINSLEY SANATORIUM.

This institution, on the breezy high land at Winsley, 400 feet above sea-level, overlooking the beautiful Limply Stoke Valley some miles from Bath, has been established for tuberculosis patients from Wiltshire, Bath, and Bristol. The hospital is administered by a joint committee representing the three authorities, the Bath Corporation maintaining fourteen beds.

The sanatorium was opened in 1904 for sixty patients, and the original cost, including land, was £32,700. In 1912-13 the institution was enlarged at a cost of £12,000, and accommodation is now provided for 119 patients. During 1924, 371 patients were admitted (219 males and 152 females), the average period each patient remained in the institution being 114.4 days. A tendency has been noted recently for patients to remain in the sanatorium for longer periods, with consequent increased benefit. Since the opening of the sanatorium 6,896 patients have been admitted.

## MINISTRY OF PENSIONS HOSPITAL.

The Ministry of Pensions Hospital, easily reached by the Weston train, which stops at the gate, is a hatted hospital, situated at some height above the city, to the north of the Lansdown cricket ground. It is built of uraltite on brick foundations; the building plan is based on a long corridor running east to west, the operating room, physiotherapy department, kitchen, stores, etc., projecting to the north and wards projecting to the south.

Originally the hospital was the Bath War Hospital, but was taken over by the Ministry of Pensions in 1920. The hospital formerly held 530 beds, but has now been reduced to 369 beds, and part has been handed over to the Orthopaedic Hospital for Children. It treats all classes of male patients who are Navy, Air Force, or Army pensioners, except mental cases and patients with pulmonary tuberculosis, diabetes, and paralysis, for which cases the Ministry has special arrangements. There is an officers' ward, and also a separate ward for dysentery cases. There is a very good x-ray department and a modern pathological laboratory, and there is an excellent artificial limb centre for legs, where the most modern artificial limbs are supplied. Artificial arms are supplied from Southampton.

During the last five years the admissions have averaged annually 100 officers and 2,245 other ranks, and the discharges have averaged 112 officers and 2,255 other ranks; 4,277 operations have been carried out, but the number is rapidly diminishing; nevertheless a considerable number of foreign bodies are still removed.

The medical and surgical staff consists of part-time and whole-time medical officers, the part-time medical officers being some of the leading physicians and surgeons from Bristol and Bath. The hospital draws its cases from the counties of Devon, Cornwall, Somerset, Wilts, Gloucester, and Dorset, and, in

addition, its cases of tropical diseases from South Wales. There are also occupational workshops where basket-making, carpentry, painting, and sign-writing are taught.

#### THE HOT MINERAL BATHS.

From the point of view of the visitor to a spa the medical institution of greatest interest is the bathing establishment, and we propose to give a short description of the baths of Bath in a later issue.

In its oldest portion the establishment dates from the first century, and the next article will give some notes about the history of the baths in the early days, as well as a brief account of the hydrological methods now employed in administering the hot springs.

### DAZZLING BY MOTOR-CAR LAMPS.

#### PROTECTIVE DEVICES.

A MEMBER has sent us a pair of spectacles which his motor driver has had made to his order and finds of much assistance in driving.<sup>1</sup> The spectacles are fitted with chloros tinted plane lenses of kidney shape set with the hilum downwards. The effect of these lenses is to give protected vision when looking directly forwards and upwards, but clear unprotected vision below the horizontal level over which the lenses do not extend.

We have referred the device to Mr. N. Bishop Harman, F.R.C.S., who sends us the following note on the general question of dazzling lights on motor cars. There are, in fact, two classes of users of the road to be considered—the drivers of the cars and the pedestrian—to whom may be added, as a subclass, the rider of an ordinary "pushbike." Speaking first of the device submitted to us Mr. Bishop Harman writes:

The idea is very similar to that of some other fittings on the market—for example, bifocal lenses with an upper tinted section, or with a tinted lateral section, and somewhat of the same order as the tinted flaps of glass or celluloid which may be affixed to the wind screen of the car or to the cap of the driver. Of all these protective appliances we have found the last mentioned—the tinted flap attached to the driver's cap—the most useful. This may be turned down over the eyes in a moment, and as rapidly turned back when not needed. Some sort of protection is needed when driving an open car with the hood down, but driving a closed car or one with the hood up is, in our experience, less difficult. When a car with bright, glaring headlights approaches, we have found that, by sitting up high on the seat instead of lolling back, it is possible to cut off the view of the approaching car and yet see the road for a distance sufficient to drive by the left-hand edge of the road with safety, both to oneself and to possible pedestrians. This device has removed the need for special glasses. Further, evening driving with the hood up is better for other reasons. At twilight the sky may be relatively bright, and so disturbing that the roadway is not easily seen; interposing the hood corrects this and the road is distinctly seen again. None of these measures protects the driver from a more serious and troublesome form of dazzle. The new motor roads are so brilliantly polished that when driving in the direction of the sun the reflection from the road surface is so intense that driving becomes painful in the extreme, as well as dangerous. Tinted glasses, provided the tint be deep enough, relieves this for a time, but not for long; soon the eyes become adapted to the new conditions, and the contrast between the brilliant road and the darkened surrounding parts is as great. Actually the glasses seem to deepen the darkness of the non-reflecting areas, and by contrast make the road reflection worse. Relief from this danger can be obtained by fixing a sheet of cardboard on the lower part of the windscreen so as to cut off the view of the road surface for some distance. Temporary relief can be obtained from transient blinding on a winding road by holding one hand below the eyes so as to reduce the view.

The motor driver is also subject to disturbance from the many reflecting parts of his car fittings upon the

dashboard, screen, and bonnet. If he prefers glittering show to comfort then he will put up with the inconvenience; but if, like the doctor, he is driving with a purpose, he will obscure the shining parts with some suitable flat, black preparation.

The pedestrian has not been considered in the foregoing notes, nor has the cyclist. The motor driver owes a duty to these, and so do these to him. Let us consider the duty of the latter first. Every doctor knows that driving at night in the country is made many times more difficult than it should be owing to the necessity for straining the eye to catch sight of almost invisible walkers and cyclists. If these would do but one simple thing motor drivers would be relieved of this strain, and without doubt the gratitude of the driver would redound to the advantage of the other road users. A white cloak, scarf, or armband, or anything white about the dress, will make the walker or cyclist so conspicuous as to be perfectly safe from the car driver. It has been noteworthy in recent months, during the vogue of the pink silk stockings for girls, how easily their wearers are seen in the light of only the side lamps, whereas their attendant swains in their duller clothing are invisible in the rays of the head lamps! If country people would wear something white at night when on the roads they would be quite safe.

There have been many devices for the protection of other road users from the glare of the car lights; so far none of these has been sufficiently successful and safe to warrant its general use. Many of them are costly, and the cost is not in proportion to their value. We recently read an account of an experimental fitting, which seemed on the face of it to promise a real measure of success, and to be at the same time simple and reasonably priced.

In the April number of the *Morris Owner* (p. 219) there is a letter from a Mr. Gossip of Inverness, with a photograph of a device for which he has taken out a provisional patent. There is affixed to each headlamp a cowl, very like the sometime popular "Dolly Varden" hat. The cowl is pivoted on each side of the rim of the lamp, and has attached to it a lever; this lever is controlled by a Bowden wire, so that the cowl can be dipped forwards over the lamp directing the rays on to the road, instead of allowing them to shine out horizontally. It is said that experiments proved that the device brought the lamp rays into such perfect control that other road users were entirely free from dazzle. A rough test we have made with such cowls confirms this view, and also the statement that there is no loss of necessary illumination to the driver such as arises when dimming is resorted to.

The discovery of simple practical devices will warrant some general regulation for the safety of all road users. We commend the use of the white scarf or armband to walkers and cyclists, and to drivers the necessity of care for those who use the road with as much warrant as themselves.

### ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee thirty-one cases were considered and £547 voted to twenty-eight applicants. The following is a summary of some of the new cases relieved.

M.R.C.S.Eng., 1894, aged 55, unmarried, was a major in the R.A.M.C. A mental breakdown has rendered him unfit for any further work. A brother and four sisters have contributed £130 towards his support, but no contribution of £50 per annum has ceased owing to the contributor's ill health. The Fund was asked to make a grant to cover this amount, and £30 was voted in twelve monthly instalments.

Widow, aged 57, of M.R.C.S.Eng. who died in 1922. Applicant has tried to support herself by taking boarders, but owing to ill health and lack of boarders has got into debt. Her debts amount to £23. Income from boarders £117. Voted £18 in twelve monthly instalments.

Widow, aged 31, of M.B.Aber., who died from tuberculosis in August, 1923. She and her daughter, aged 6, are left with £3 a week, which will last for another eighteen months. She pays her parents £2 10s. a week for herself and child for board and lodging. Applicant is training as a hairdresser; the Scottish Corporation found the sum of £30 for the course, and asked the Fund to help towards this amount. £15 was voted.

M.R.C.S.Lond., aged 68, who practised until ill health compelled him to give up. His daughter has supported herself and her father, but is now trying to get him into a home, as he requires constant attention. The boarding-house which the daughter has had is a failure, and she is now seeking a post so as to be self-supporting. She asks for a grant as the applicant has no income. Voted £40 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., C.B., M.S., at 11, Chandos Street, Cavendish Square, London, W.1.

<sup>1</sup> Made by James Woodcock and Sons, 259, Glossop Road, Sheffield.

## British Medical Journal.

SATURDAY, JUNE 6TH, 1925.

### ROYAL OPENING OF OUR NEW HOUSE.

THE new house of the British Medical Association, in Tavistock Square, London, is rapidly approaching completion. On Monday, July 13th, it will be formally opened, and the ceremony will form the first of a series of functions which will engage the activities of members of the Association until the close of the Annual Meeting in Bath on the 27th of that month.

The Patron of the Association, His Majesty King George, has graciously consented to open the New Building, and will be accompanied by Her Majesty Queen Mary. The occasion will be memorable in the history of the Association, and impressive as a demonstration of the essential solidarity of the medical profession in this country and throughout the British Empire.

A strong Reception Committee, comprising the distinguished Presidents of the Royal Colleges of Physicians and Surgeons and the officers and other prominent members of the British Medical Association, is presided over by the Chairman of Council. Invitations will shortly be issued to all the important professional bodies in the country, and it is anticipated that the representatives of Medicine throughout the land, and officers of bodies cognate with the Association, will be well represented at the opening function. It is hoped that every Division and every Branch in the country will be able to send a representative to participate. The presence of Dominion and Colonial delegates is already assured. Our brethren in the United States have intimated that the President-Elect of the American Medical Association, with probably at least one other eminent colleague, will be present, and it is also anticipated that medical men of distinction from allied countries, who will subsequently take part in the scientific proceedings at the Bath Meeting, will attend the function.

As a preliminary to the actual opening ceremony His Grace the Archbishop of Canterbury has consented to dedicate and open the magnificent memorial gates which the British Medical Association has provided as a tribute to those of its number who fell in the great war. These gates, of which some preliminary account appeared in the *BRITISH MEDICAL JOURNAL* of May 2nd (p. 853), are now in course of erection at the front of the main courtyard.

The opening ceremony will include the presentation of officers of the Association and prominent visitors, together with the representative delegates from the Dominions, Colonies, and foreign countries. The function itself will take place in the Great Hall of the

New House, which the artistry of Sir Edwin Lutyens, R.A., the architect of the building, has so fashioned as to make a fitting frame for such a ceremony. Following upon the ceremony the building will be open for inspection by the invited guests. On the evening of July 13th a reception and conversazione will be given, and it is hoped that the Metropolitan Counties Branch may be able to arrange a similar function for the night of Tuesday, July 14th, which will provide an opportunity for many others, unable to be present on the first day, to view the building.

### UTILIZATION OF VITAL STATISTICS.

"According to Herodotus, Xerxes wept at the sight of his army, which was too extensive for him to scan, at the thought that a hundred years hence not one of all these would be alive. Who would not weep at the thought in looking over a big catalogue that of all these books not one will be in existence in ten years' time?" This was the reflection of Schopenhauer, and a visitor to the library of the Royal Statistical Society, to that section of it which contains the endless volumes of official vital statistics of so many nations, will appreciate its force. Yet these dust-covered volumes, if we could but master their contents, would teach us many things. Comparison of the rates of morbidity and mortality of the same diseases under different economic, climatic, and sociological conditions, ought to bring a wider comprehension of the essential factors of mortality and a truer understanding of the relative importance of the measures to which the decline or increase of this or that disease has been attributed. But the collation of vital statistics is not an easy task. The reports of national statistical departments are primarily designed for the information of the public and officials of the country of origin. Before the tabular matter can be profitably used the inquirer may need knowledge which it may happen is not given at all, or given in a form a foreign reader cannot understand. Even our own vital statistics present difficulties, such as the varying connotation of the word "county," which make the way of the foreign student hard. The Englishman who approaches, without preparation, the official documents of another country will often need assistance. It is, of course, obvious that a good many difficulties must remain even when all the assistance that can be given has been given. The most sedulous study of a Baedeker, even combined with a three months' course on X. Y. Z.'s system of how to learn Dutch without a master, will not fit a Londoner to lecture in the University of Leyden; yet it will most certainly enable him to get more out of a visit to Holland than if he had depended solely on his native wit.

The Health Organization of the League of Nations has projected a series of statistical handbooks—Baedekers of the vital statistical publications of the nations. The first two volumes have now been issued.<sup>1</sup> These volumes describe the publications of the Netherlands and of Belgium. They explain what is in each of the publications and how the information has been obtained; they call attention to striking peculiarities, whether of method or result, and make brief comparisons with the data of a third country, England and Wales. The volumes are compiled on a uniform plan.

<sup>1</sup> League of Nations—Health Organization—Statistical Handbooks Series, No. 1, *The Official Vital Statistics of the Kingdom of the Netherlands*, pp. 77. No. 2, *The Official Vital Statistics of the Kingdom of Belgium*, pp. 84. Geneva, 1924.

Following a short general introduction, the method of taking the census is described, and then the contents of the most recent census reports are noted. Next follows an account of the system of birth registration, then a specification of the information respecting births and birth rates contained in the various publications of the central department. Registration of stillbirths and the published information regarding them are described. There follows an account of the registration of deaths and detailed contents of the published information. Morbidity statistics (nature of data and method of publication) are then treated. A summary of the information published by municipal offices is included, and, in a general conclusion, salient features are noted.

It may certainly be said that a few hours' study of this work would enable any intelligent person to consult the official publications of the country with a clear knowledge of what sort of information he will find in them, and—an important point—over how many years that information is available. The value of such guides as these to the epidemiologist and student or official concerned with public health problems should be very great. When this series is completed knowledge now possessed by a few—a very few—specialists will be open to all the world.

Already, at the beginning of the series, information is afforded which should interest the public health worker. We may illustrate the point by a few examples taken from the guide to the Dutch statistics. Probably few foreigners are aware of the minute accuracy with which data of infant mortality and stillbirths are tabulated in Holland; here is ample material for a comparative study, and therefore need of the warning: "Attention is called to the fact that, unless specially mentioned, 'stillborns' include a proportion of children born alive but dying before registration (that is, within three days of birth), such births being inscribed with the endorsement 'presented dead' and legally regarded as 'stillborn.'" The remarkable contrast between the ratio of female to male mortality from pulmonary tuberculosis is also worthy of attention. While in England and Wales the rate of mortality among males considerably exceeds that among females, in Holland the reverse is found. In 1921 the English rates per 100,000 living were 100.2 for males and only 77.7 for females; the corresponding rates in Holland were 87.0 and 103.0. This is an essentially recent change in Dutch experience (in 1901 the rates were: for males 140, for females 135), and its explanation might throw some light upon the general problem of etiology. In Belgium male mortality from pulmonary tuberculosis has exceeded female mortality during the last twenty years, but the rates in 1921 were the same for the two sexes, so that the position is intermediate between that of the Netherlands and England and Wales.

Very instructive comparisons of the rates of mortality and morbidity of the zymotic diseases are also possible. It is noted that, while formerly the rate of mortality from diphtheria and croup in the Netherlands used often to be higher than in England and Wales, since 1894 the position has changed, and in 1920 and 1921 the rate in Holland was not much more than 50 per cent. of the English rate. There appear also to be differences of incidence, but the caution is rightly given that comparisons of incidence are hazardous, because the adoption of a bacteriological instead of a clinical criterion may greatly change the recorded incidence of the disease.

The object of these handbooks is, not to summarize the actual contents of the official reports, but to

indicate what data are in fact to be found in them, so that such comparisons as we have mentioned only occupy a small part of the volumes and anything of the nature of criticism is—rightly, we think—excluded. Mere guides, however useful, are not, of course, suitable for continuous reading, but we hope the compilers will not refrain from the insertion of such notes as we have mentioned in future volumes, particularly in those which deal with populous countries. Students will be encouraged to consult the original publications if their attention is directed to peculiarities. In planning this series of handbooks the Section of Hygiene of the League of Nations has shown excellent judgement, and is making a very useful contribution to knowledge; we shall look forward with interest to future numbers in the series, which, when completed, will form a most valuable addition to the working library of the public health official or student of medical and vital statistics.

#### AFRICAN SLEEPING SICKNESS.

In the last two issues of the JOURNAL we have given an account of the International Conference on Sleeping Sickness recently held in London. According to the history of the disease given in the *Manual of Tropical Medicine* by Castellani and Chalmers, the disease was first observed by John Atkins in 1721, who published a description of it in a book entitled *The Navy Surgeon*, published in 1734. He called it "the sleeping distemper," and said that it was common among the negroes on the Guinea Coast. Winterbottom described it again in 1803, from observations made on the west coast of Africa, near Sierra Leone. The first case was brought to London in 1891, and was studied by the late Sir Stephen Mackenzie. In 1900 two more cases were under the care of Sir Patrick Manson in London; the morbid anatomy of these cases was studied by Sir Frederick Mott, who did much to clear up the pathology of the disorder. The disease was then generally known as "negro lethargy"—not, perhaps, a very good term, as human infection with trypanosomes does not always produce the sleepiness, and the trivial term "sleepy sickness" applied by the newspapers to epidemic encephalitis has now even found its way into the official proceedings of the House of Commons. The disease is characterized by an inflammatory condition of the lymphatic system, which may lead to meningo-encephalitis, to which the characteristic lethargy is due. It was not, however, until the discovery of the trypanosome and of the fact that it was spread by a fly (*Glossina palpalis*)—an observation made by Castellani and by Sir David Bruce and Dr. Nabarro—that any real progress could be made in the study of the mode of dissemination of the African disease. Reports recently submitted by the experts committee of the League of Nations<sup>1</sup> show that the situation is still serious. In its second report this committee made definite recommendations concerning the various subjects to which attention should specially be directed at the present time. These matters were considered at the recent conference in London, which made a series of recommendations; these were reported last week at page 1014. As was there noted, an expert International Commission is to assemble at Entebbe, Uganda, at the end of this year or the beginning of 1926, and it is to make a report after studying the methods in use in Uganda, which is a suitable area from several points of view; in addition to the possession of a well appointed laboratory in Entebbe, it is the district where sleeping sickness was apparently mastered by

<sup>1</sup> This Committee consisted of Dr. Andrew Balfour, C.B., C.M.G., Dr. E. Van Campenhout (Belgium), Professor Gustave Martin (France), and Dr. A. G. Bagshawe, director of the Tropical Diseases Bureau, London. Its report on tuberculosis and sleeping sickness in Equatorial Africa was submitted to the Health Committee of the League of Nations last April.

the removal on a large scale of the infected population from the endemic areas. Repopulation of the abandoned areas is now proceeding, and special investigations are being carried on among them. It also affords ample opportunity for the study of cattle, and the blood of situtunga antelopes, of varanus lizards, and other wild animals can be examined; while, not very far away—in Kavirondo—cases of human sleeping sickness are available. Again, it is easy to get from Entebbe to Mwanza on the southern shore of Lake Victoria, and some few days' journey from Mwanza lies the area where Mr. Swynnerton has been conducting his remarkable large-scale preventive measures, of which he has given an account in our columns. The demonstration of Mr. Swynnerton's methods and the opportunities afforded by this part of Tanganyika Territory for a further study of the big game problem cannot fail to be of value to the Commission. The chairman of the local International Commission is Dr. H. L. Duke, bacteriologist to the Uganda Protectorate, who eleven years ago contributed to this JOURNAL an article on wild game as a reservoir for human trypanosomes, and has since been engaged in a study of the problem in all its aspects in Uganda. France will be represented by Dr. Lavrier, and Belgium by Dr. Van Hoof. Dr. Kleine will also be a member of the Commission; he has been selected for his wide knowledge of some of the problems to be solved, and for his special experience in their investigation. The Commission will be completed by the appointment of a biochemist, an entomologist with local knowledge, and a European laboratory assistant. The appointment of such a commission is a new departure so far as tropical Africa is concerned, and is frankly of an experimental nature. It was therefore considered desirable that its mandate should be definitely limited to a period of one year.

#### MURDER AND INSANITY.

THE M'Naghten rules, which have governed the defence of insanity in murder trials since they were laid down in 1843, have once more been the subject of criticism—this time by the members of the Medico-Legal Society. A report of the debate appears at page 1038. The law of England assumes a man to be sane, and therefore responsible for any crime he may commit, until proved insane to the satisfaction of a jury. The onus is upon the defence to prove that at the time the accused committed the murder he was labouring under such a defect of reason resulting from mental disease as not to know what he was doing, or, if he did know this, yet he did not know that what he was doing was wrong. Dr. Weatherly, in his introductory paper before the society, said that excluding idiots, imbeciles, and many chronic dementals—who might presumably be included in the category of those who would not know what they were doing—the judges who laid down the rules of 1843 would have found very few inmates of modern asylums of whom it could confidently be stated that they had no proper knowledge of right and wrong. This view has long been held by very many members of the medical profession, and it is to be remembered that the Committee presided over by Lord Justice Atkin recommended that if a man commits a crime under an uncontrollable impulse due to mental disease, he ought not to be held responsible for it in law. This recommendation, however, does not find favour with all members of the legal profession. Lawyers who hold a different view say that though the M'Naghten rules may be open to criticism, yet until some satisfactory substitute can be found it is safer to rely upon the fairly definite statement of legal insanity contained in those rules than upon indefinite theorizing about what is an irresistible and uncontrollable impulse. As to Dr. Weatherly's statement that most lunatics can distinguish right from wrong, Lord Brougham's oft-told

tale is, perhaps, worth recalling. Patients in York Asylum, so it is said, discussed together the case of the incendiary Martin, when on his trial for attempting to burn York Cathedral, and came to the conclusion: "He will be all right; for he is one of us, so the law will take no notice of him." Dr. John Campbell, relating his experiences as a medical officer to H.M. Prisons, said that lunatic prisoners, after assaulting a prison warder, would sometimes say, "You can't touch me; I am a lunatic." The question arises: Ought insane persons, then, who seem to know right from wrong, to be immune from the penalties of our criminal law just because they are declared to be lunatics? The view of the legal profession is that the answer is to be found in the third M'Naghten rule—that if the accused was conscious that the act was one which he ought not to do, and if that act was at the same time contrary to the law of the land, he is punishable. The recommendation that the sufferer from irresistible impulse should be immune was criticized by some legal members of the Medico-Legal Society, but Lord Justice Atkin pointed out that such an impulse, to afford immunity, must arise from a disease of mind. He cited the most usual case before our criminal courts—of the mother of a young family, deserted by her husband, who several times resisted the impulse to put an end to her children's existence of semi-starvation; that impulse eventually became an obsession, and, there being no hope of future sustenance, she killed her children. Here, surely, it is argued, there is no disease of mind of such a character as would enable her to set up a plea of irresistible impulse arising therefrom. However, as Lord Justice Atkin said, in such cases the jury always takes the merciful view, and the woman is found "Guilty but insane," despite the M'Naghten rules. Dr. Weatherly adumbrated two questions for a jury in substitution of the M'Naghten rules: (a) that the prisoner was suffering from a disease of mind; (b) that the crime was the outcome of that disease. The objection of the legal profession to these, as we understand it, is that they wholly ignore the axiom laid down in Rule 3, or, alternatively, that (b) is satisfied by Rule 4; where a criminal act is committed by a man under some insane delusion as to the surrounding facts which conceals from him the true nature of what he is doing, he will be under the same degree of responsibility as if the facts with respect to which the delusion exists had been as he imagined them to be. The oldest illustration of this rule is what is called the Dresden china case, where the accused man was in the habit of dusting his servants every day under the delusion that they were pieces of Dresden china, and, being angered while engaged in this occupation, he aimed a fatal blow at one of the servants. What we conceive to be the view of the legal profession on this difficult matter is that to alter the present law is inexpedient because the medical profession is not unanimous about what constitutes insanity. Medicine has, of course, made great strides in the study of mental disease since 1843. But (so the legal argument runs) until the medical profession can put forward something to replace the M'Naghten rules—which harmonize with the oldest of criminal law maxims, *Actus non facit reum nisi mens sit rea* (that you cannot have a criminal act without a guilty mind), upon which the question, "Did he know that what he was doing was wrong?" is based—it is doubtful whether a solution will be found which proves acceptable to both the medical and legal professions and also to the general public.

#### CHEAP AND NASTY SPECTACLES.

A NUMBER of multiple shops are being opened throughout the country, where every article for sale is at a low and fixed price. We do not wish to comment upon the general run of the articles for sale: some of them may be of excep-

tional value and of real use; others are dangerous and dear at any price. A reader has given to us a pair of spectacles he purchased from one of these shops—a huge piece of shining wood, metal, and plate glass. Spectacles were on sale at sixpence a pair. The pair he bought purported to correct his presbyopia, the degree of which he knew. The spectacles seem to be of foreign make. The frames are of rather soft iron, coated with some mercury gilding which makes them look attractive. The bridge is a useful W-shape, the joints are well soldered, and the hinges of the bows undoubtedly ingenious. So far as the frames go no objection need be made at the price. But the lenses are otherwise. These are plano-convex of +3 diopters. The lenses appear to be cast and unpolished. The surfaces are pitted all over, so that they look like a coarse imitation of the pores of the human skin where the sweat glands are most numerous. But this is not the worst. One lens is centred correctly, but the other is decentred downwards, so that there is in effect a 2.5 degree prism, base down, set in that lens. Such a defect will produce in the wearer of these glasses all the discomfort and strain of hyperphoria or latent vertical squint, perhaps the most troublesome of all defects of muscle balance. It is to be hoped that vendors of these spectacles, in the interests of the community generally, will cease to sell them, unless they are sold with plane lenses for the amusement of children.

#### A SALE OF OLD MEDICAL BOOKS.

ANOTHER of the old family libraries of the English aristocracy is catalogued for sale by auction, and proves to be rich numerically in old medical works, though few of them are of sensational value from the collector's point of view. The library in question is that of the ninth Lord Middleton, which is being sold at Christie's on June 15th, 16th, 17th, and 18th; many of the books are attributed to his ancestor, the first peer, previously Sir I. A. Willoughby, who evidently took a strong interest in contemporary medicine and anatomy. Thus there are Bartholin's treatise on the latter subject, with his portrait, 1654; Glisson's "Anatomy of the Liver," 1665; Barbette's "Surgical Anatomy," 1672; Swammerdam on respiration, 1667; Mayow on the same topic, and on rickets, 1669; Thurston, also on respiration, 1670; Bartholin on the genital tract, 1664; Vesling on anatomy, 1661; Blasius on the anatomy of animals, 1681. More important than any of the foregoing is Thomas Gemini's translation into English of Vesalius's great textbook of anatomy (Basle, 1543), one of the first books in English illustrated by copperplate engravings, 1559; earlier still is Mundinus's "Anatomy" of 1513. Among many other books on medicine and surgery are those of Timothy Bright on the sufficiency of English medicines, 1580, and on melancholy, 1613; of Haworth, on the "New Spaw" (in Long Acre!), of Isaac Barrow on vision, 1699, and of Christopher Scheiner on the eye, 1652. There is a copy of Sir Thomas Elyot's "Castel of Helth," 1541, not the first edition, seemingly, bound up with Cary's herbal, "imprinted at London in fletestrete at the sygne of the George next to Seynt Dunstones church by me Wyllyam Myddylton in the yere of our Lorde DCCCCXLVI, the thyrde day of July," which is extremely rare. There is also a copy of Linaere's edition of Galen, 1541, in a binding of stamped pigskin, which is dated 1544 and gives additional value to the contents. With this may be mentioned Robert Sprackling's "just and plain vindication of Hippocrates and Galen," 1665. About nine medical tracts by Glauber, 1651-58, are bound together in one volume; Highmore and Willis and Sydenham are other seventeenth century worthies whose names occur in the catalogue. William Harvey is represented by two works, and his namesake Gideon by one. Another edition of Galen is that of

1561, bound in contemporary vellum with the arms of Cambridge University on the sides; while there is also a very interesting copy of the works of Hippocrates (the first Aldine edition, published at Venice in 1526). There are several pharmacopoeial volumes; perhaps the most interesting is the first edition of the "London Pharmacopoeia," drawn up in 1618 by the Royal College of Physicians. The "Hortus Sanitatis" of Joannes de Cuba, 1517, is bound up with John of Vigo's "Surgery" of 1514. The latter author is also represented in an English translation (by Bartholomew Traheron) of 1550. Even more ancient is John of Gaddesden's book on medicine, printed in 1492, but compiled about 1314. As early as 1628 it occurred to Castellus—and possibly to others—that blood-letting was being overdone, for in that year he published at Rome a treatise on the abuse of phlebotomy, a copy of which appears in this sale. Two more tracts on phlebotomy, for and against, dated 1671, are bound in with other medical and scientific pamphlets, one of which deals with the cure of adder bites. In 1634 appeared the third edition of Peter Lowe's "Whole Art of Chirurgie," of which also a copy is offered; two copies of the rare first edition of this work have been seen in London salerooms in the last year or two. Later in the catalogue is seen "Willis on the Brain and Nerves," bound with "Diemerbroeck on the Plague"; the last items of any medical importance are Wecker on remedies, 1588, and Bruel on the theory and practice of medicine, 1585. Altogether this is an assortment of medicaliana which shows the catholic taste of Thomas Willoughby, by whom most of the library appears to have been collected.

#### CANCER COMMISSION OF HARVARD UNIVERSITY.

WE have recently received the twelfth annual report of the Cancer Commission of Harvard University for the year ending June, 1924. The commission was founded in 1899 for the study of the cause of cancer. In 1912, further funds being available, a special hospital was built for the study and treatment of cancer patients. During the earlier years of the commission's work investigations were carried on in the laboratories of the Harvard medical school—investigations which had to do chiefly with the possible parasitic cause of cancer, a question much discussed at the time. In more recent years inquiries were extended to include a study of the pathology of the spontaneous and inoculable tumours of animals, and under Professor E. E. Tyzzer contributions of great value were made to the tumour problem. With the construction of the special cancer hospital and the advent of radium and x rays as agents for the treatment of cancer, a new department of investigation came into existence—that of bio-physics. Since 1922, when further laboratories were completed, it has been possible for all the work of the commission to be assembled under one roof, with facilities for the effective treatment of patients with x rays, radium, or surgery. Laboratories have been built for the investigation of various problems in chemistry, pathology, and bio-physics which are likely to contribute toward the solution of the cancer problem. The latest report shows that great activity is afoot in nearly all the departments of this well equipped hospital. This document consists of a general review of the policy of the year and a series of special reports by the surgeon, physician, research fellows in physics, bio-physics, and chemistry. Like all similar reports, this only refers in general terms to the work which is at present in hand, but the remarks that are made about some of the researches, particularly those connected with bio-physics, suggest that important developments are near at hand.

## CHARCOT BIBLIOGRAPHY.

On Monday, June 15th, at the social evening of the Royal Society of Medicine, Dr. Farquhar Buzzard, President of the Section of Neurology, is to give an address on Charcot, as a part of the ceremonies in celebration of his birth one hundred years ago, and Mr. W. G. Spence has prepared a bibliography of Charcot so far as is represented in the publications in the library of the society. The bibliography is a voluminous document arranged chronologically from the year 1851, when, as an interne of the Hôpital de la Charité, Charcot made eleven reports to the Société de Biologie, down to 1893, when he published simultaneously in English and French an essay on the Faith Cure. During the evening the Library will be open, and books and articles by Charcot and his pupils will be on view. Fellows and guests will be received by the President, Sir StClair Thomson, at 8.30 o'clock.

THE "BRITISH MEDICAL JOURNAL":  
NEW ADDRESS.

DURING the Whitsun holidays the Editorial and Printing Departments of the *BRITISH MEDICAL JOURNAL* were removed from 429, Strand, to the new headquarters building of the British Medical Association in Bloomsbury. The postal address for all communications intended for the Editor is now "*BRITISH MEDICAL JOURNAL*, British Medical Association House, Tavistock Square, W.C.1," the telephone number of the Editorial Department is Museum 2864, and the telegraphic address "Aitiology, Westcent, London." Until further notice is given in these columns, all communications with reference to advertisements, as well as orders for copies of the *JOURNAL*, should continue to be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2. It is expected that the Medical Department and the Library of the Association will be removed about June 17th, and the Finance Department about June 19th.

The Registrar of the General Medical Council informs us that an official communication has been received from the Privy Council notifying that the agreement with Italy regarding medical reciprocity was signed on May 21st.

The Croonian Lectures before the Royal College of Physicians of London will be delivered on June 9th, 11th, 16th, and 18th, by Dr. S. A. Kinnier Wilson. The subject is "Disorders of motility and of muscle tone, with special reference to the corpus striatum." The lectures will be delivered at the College, Pall Mall East, at 5 o'clock.

The annual general meeting of the Research Defence Society will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, on Tuesday, June 9th, at 3.30. The chair will be taken by the President, Lord Lamington, G.C.M.G., G.C.I.E. A short lantern lecture will be given by Dr. R. A. Lyster, M.O.H. for Hampshire, and lecturer on preventive and State medicine at St. Bartholomew's Hospital, on "Our defences against small-pox." Tea and coffee will be served after the meeting.

The annual dinner of the Harveian Society of London will be held in the Connaught Rooms, Great Queen Street, W.C.2, on Thursday, June 11th, at 8 p.m.

The annual conversazione of the West London Medical-Chirurgical Society will be held at the Kensington Town Hall on Friday, June 12th. The president of the society will hold a reception at 8.30 p.m., and at 9 o'clock the Cavendish Lecture will be delivered by Sir Humphry Rolleston, Bt., Regius Professor of Physic in the University of Cambridge.

INTER-STATE POST-GRADUATE ASSEMBLY  
OF AMERICA.

## INAUGURAL PROCEEDINGS.

The Inter-State Post-Graduate Assembly of America, which met in London from June 2nd to 4th, under the leadership of Dr. Charles H. Mayo, was attended by 550 medical men from the United States and Canada. The visitors represented every State in the Union and every Province in the Dominion, and Dr. Mayo announced that 60 per cent. of them were general practitioners. A very busy medical programme was completed, and there was also a full social programme, chiefly for the benefit of the ladies, who numbered 200, accompanying the party.

H.R.H. the DUKE OF YORK presided at the opening ceremony in Wigmore Hall. The hall was filled with the visitors for almost an hour before the proceedings were timed to begin, and the acclamations with which familiar figures were greeted had a gusto which was a little unusual for medical gatherings on this side. The Duke of York briefly welcomed the "fellow workers in the great army of skilled physicians and surgeons," and expressed his hope that when the visitors left these shores it would be not only with some additions to their professional knowledge, but with the happiest recollections of their stay. Dr. Mayo was to be congratulated upon the organization which in nine years had done so valuable a work and achieved so important a position. He also congratulated Mr. Philip Franklin, the honorary organizer of the meeting, on the result of his efforts.

The Right Hon. NEVILLE CHAMBERLAIN offered a welcome on behalf of the Government, and especially the Ministry of Health. To cross the Atlantic was no longer a serious or perilous adventure, but he supposed that many of those present must have travelled hundreds of miles on land before embarking, and all of them must have had to make special arrangements for the carrying on of their practices. It was a compliment of no mean order that they had found it worth while to come and see what Great Britain was doing. This small island felt the honour of opening its arms to embrace the profession of a continent, and it was an impressive thought that the visitors would carry back the results of their observations to so wide a territory. Not that they would all tell the same story, or they would be unlike their British confreres, who showed a healthy independence of mind. The benefit of the meeting would not be confined to the other side of the Atlantic; physicians and surgeons in this country would gain much from the contact.

Sir HUMPHRY ROLLESTON, Bt., P.R.C.P., said that although language and ideals were identical on both sides of the Atlantic, there was necessarily, owing to the respective environments, a certain amount of difference in views and methods. Post-graduate education was a very urgent problem in London, and the profession here had much to learn from America in this respect. Less than ten years ago there was a Tri-State Assembly out of which the present organization had expanded until it embraced every State of the Union and every Province of Canada. On this side they had reflected with what joy Sir William Osler would have welcomed that occasion, and this had inspired them to do everything in their power to ensure an instructive and useful visit.

Sir JOHN BLAND-SUTTON, Bt., P.R.C.S., after referring in a teasing way to some other forms of migration and pilgrimage, said that this was the greatest invasion of doctors from America into our island within living memory. At the back of this irruption was an intellectual hunger combined with a certain amount of curiosity. It was one thing to gather the opinions of physicians and surgeons from their effusions in medical journals or other legitimate forms of advertisement, and another thing to meet them face to face in their own wards and operating theatres, or, better still, over a meal or a pipe, where lasting friendships could be formed.

The American Ambassador (His Excellency the Hon. A. B. Houghton) expressed the thanks of the visitors to His Royal Highness. This occasion was one more evidence of the reality of those friendly ties which bound the countries and peoples together. The comradeship of the British and American medical professions, so manifest during the agony of the war, was to be furthered and perpetuated in the time of peace. He addressed to his compatriots a word of gentle admonition. It was going to demand from them all the talent and knowledge they had gained in the professional experience to weather the burst of British hospitality which awaited them; he spoke as an expert. Nowhere else would American doctors find a hospital so generous and gracious, though potentially so dangerous, as in the ancient home of their forefathers.

Dr. CHARLES H. MAYO said that this Royal welcome would add to the warmth of feeling for the Mother Country which existed in the States, even as the gathering itself would do something to promote the supremacy in scientific work of the English-speaking peoples. He added that the Assembly had one honorary member—Mr. Coolidge, President of the United States—and he now had authority to invest another distinguished person with the honorary membership—namely, the Duke of York.

George CRILE, expressing his regret that he was prevented from attending, and adding that the company who had come over were some of the finest and most earnest men in the profession in North America. Both they and the members of the profession who had remained behind keenly appreciated the arrangements which had been made for them.

#### FIRST SESSION.

##### Gall-bladder Disease.

At the first morning session four lectures were delivered, the first by Sir HUMPHRY ROLLESTON on the etiology and treatment of gall-bladder disease. The lecturer discussed the two etiological factors—in the formation of gall stones, and biochemical factors—the infective and the metabolic or said that sometimes one factor operated alone, more often both factors operated together, and both must be taken into account in prophylactic measures and in treatment. There had been some scepticism as to the real value of hexamino in gall-bladder infections, but he considered that the value was beyond doubt. He dealt with prophylactic measures, in particular the restriction of foods rich in cholesterol which would favour the formation of biliary calculi; these foods were yolk of eggs, brains, fats, butter, kidneys, beans, and peas. Stagnation of bile in the gall bladder should be counteracted by frequent small meals, and by exercise, especially such as entailed free excursions of the diaphragm and the liver. It must be admitted that medical treatment was not so radical, and therefore not so satisfactory, as surgical removal of the calculi, but there were many cases where surgical treatment was declined by the patient or was inadvisable. Attempts to dissolve gall stones could not be regarded as likely to succeed. Olive oil certainly dissolved them in test tubes, but that afforded little evidence of the action which took place in the gall bladder.

##### "The First and Last Kink."

Sir W. ARBUTHNOT LANE addressed the gathering on "The first and last kink." He had formulated a law that all those changes in the body which came about in consequence of the endeavour on the part of the organism to establish a mechanical relationship with its surroundings served at first a useful purpose, but later tended to shorten the life of the individual. In no instance was this law so clearly demonstrated as in the first and last kink, the first instance simply upon the gastro-intestinal tract was in the effect of which upon the body. His observations, which had extended by septate organisms, had impressed him with the connexion between cancer and gastro-intestinal stasis. There was a mechanical and a toxic factor in the causation of cancer, and he had observed cancer fol-

so commonly upon the mechanical and toxic results of intestinal stasis that he was convinced that the sequence was no mere accident. The principles governing the treatment he now adopted in such conditions differed in no detail from those which he formulated twenty-five years ago. In milder cases the lubrication of the canal and consequent softening of the intestinal contents by the free use of paraffin was sufficient to meet the disability resulting from a moderate degree of obstruction. Suitable diet, kaolin, and bismuth were most useful adjuncts in that they controlled the spasm of the inflamed bowel. In other cases the freeing of the anchored bowels by a simple operation restored the structure and mobility and permitted the free passage of material through the liberated loop. He would not discuss the treatment of ulceration of the gastrointestinal tract and other conditions which resulted from the presence of the first and last kink, but he would draw attention to the importance of recognizing the causal relationship of all these troubles of the proximal bowel; and of the need for instructing the public in proper dieting and in the habit of evacuating the large bowel three times a day, in order that this acquired state, which was almost to be regarded as normal in civilization, might be obviated.

##### "New Diseases for Old."

Sir THOMAS HORDER spoke on some changes in the incidence and course of common diseases. Diseases, he said, had their natural history, like men and animals. Old diseases disappeared or tended to lose their virulence, new ones took their place. Cholera and typhus had gone, smallpox was going, but influenza and encephalitis had appeared. Certain diseases during the last twenty-five years had become less common—diphtheria, erysipelas, typhoid fever, anthrax, glanders, hydrophobia—thanks largely to the activity of the Ministry of Health. The comparative rarity of lead poisoning and other industrial diseases might reasonably be attributed to the sound operation of the Factory Acts. The relative infrequency of certain other diseases might be attributed to the betterment of the general conditions of life; some forms of tuberculosis came in this category, possibly rickets also. Acute articular gout seemed to be less frequent than formerly; it was not clear whether this was due to the fact that people drank less alcohol or favoured different alcoholic beverages from those favoured by their fathers. On the other hand, a series of disease processes had arrived, lacking the precision of the conditions of functional disturbance—neurasthenia in all its forms, arterial hypertension, with arterio-sclerosis in close attendance, accompanied by sequels, with myocardial defects as accompaniments or sequels, hyperthyroidism, and perhaps diabetes. There was also a large increase in affections due to *B. coli* or lactose-fermenting members of the same group, and again in cases of bacterial endocarditis associated with feebly pathogenic strains of streptococci. Then there was the large group of periodontal diseases, chronic infections of the periodontal membrane, and respiratory and digestive tracts. Most of these were due to some saprophytic strains of streptococci, resulting from lowered tissue resistance. Was it possible that they were becoming more and more the prey of their own saprophytes, and if so why? The conditions of modern life had tended to eliminate disease or render it less harmful, with the one important exception that the nervous and emotional strain of living had increased in the last two decades. Lowered resistance to microbial infection was usually regarded as due to an ill defined change in the system have some more definite and direct bearing upon infection or immunity than had hitherto been thought probable? The influence of the nervous system upon the response to bacterial infection had been too little regarded. Therapeutic must concentrate upon the means of raising the general resistance, and especially the nerve tone. Patients must be induced to live the simpler life. In the sphere of the intellect, and especially of the emotions, moderation must be preached. The pace of modern life,

the nervous strain involved, the expenditure of the energy of the spirit, had become a large factor in the incidence of disease, and of disease of a different type from that with which the physicians of a past generation were acquainted.

#### *Addison's Anaemia and Subacute Combined Degeneration.*

Dr. ARTHUR F. HURST gave the concluding lecture, on the pathogenesis and treatment of Addison's anaemia and subacute combined degeneration of the spinal cord. Something like 85 per cent. of the cases of pernicious anaemia had sooner or later some nervous symptoms, shown quite definitely to be due to degeneration of the spinal cord. These two diseases were really due to the same cause; he believed it to be an infection which began in the mouth. Both conditions were marked by an absence of hydrochloric acid in the gastric juice, and there was a good deal of evidence that this achlorhydria was not a symptom of the disease but preceded the disease. This was a familial condition, and explained the familial occurrence of Addison's anaemia. To examine the gastric contents and the blood was advisable in cases in which this condition was at all suspected, and by vigorous early treatment it was possible to prevent the anaemia and the nervous disease from developing.

Dr. Hurst next described the treatment he followed, directed in the first place to the eradication of any oral infection, and afterwards to the stomach, and the preventive measures to be taken to ward off the recurrences so common in the past. It was impossible to compare the different forms of treatment; each had its use. What he urged was a combined treatment, directed in every possible way to overcoming the intestinal infection, which seemed to be the cause of both Addison's anaemia and subacute combined degeneration of the spinal cord, at the same time overcoming the results of the infection by transfusion and by arsenic. He hoped that with further development along these lines the word "pernicious" might lose its ordinary connotation. Towards the close of his lecture Dr. Hurst described a remarkable case in his experience in which a man who had been cured of Addison's anaemia became on two occasions a very successful donor of blood to patients in a like condition.

In the afternoon twenty hospitals offered post-graduate facilities to the visitors. Later proceedings will be reported in our next issue.

### BIRTHDAY HONOURS.

The list of honours conferred in connexion with the King's Birthday on June 3rd contains the names of the following members of the medical profession, to whom we offer warm congratulations.

#### *Baronet.*

Sir JOHN BLAND-SUTTON, LL.D., F.R.C.S.  
President of the Royal College of Surgeons of England;  
Consulting Surgeon to the Middlesex Hospital.

#### *K.C.B. (Military).*

Major-General SAMUEL GUISE MOORES, C.B., C.M.G., late R.A.M.C., retired pay.

#### *K.B.E. (Civil).*

JAMES CRAWFORD MAXWELL, M.D., C.M.G.  
Colonial Secretary, Gold Coast Colony.

#### *Knights.*

JAMES BERRY, B.S., F.R.C.S.  
Consulting Surgeon, Royal Free Hospital; Member of the Council of the Royal College of Surgeons of England.

HARRY EDWARD DIXEY, M.D., J.P., D.L.  
Chairman and Honorary Secretary of the Bewdley and West Worcestershire Unionist Association for twenty-five years. For political and public services.

JOHN ROBERTSON, C.M.G., O.B.E., M.D.  
Medical Officer of Health, Birmingham; Professor of Public Health in Birmingham University.

#### *C.B. (Military).*

Surgeon Rear-Admiral ALEXANDER MACLEAN, D.S.O., R.N.

#### *C.M.G.*

ARTHUR ANDREW MORRISON, M.D.  
British Delegate on the International Maritime Sanitary and Quarantine Board of Egypt.

#### *C.S.I.*

Major-General THOMAS HENRY SYMONS, O.B.E., I.M.S.  
Honorary Surgeon to H.M. the King; Surgeon General with the Government of Madras.

#### *C.I.E.*

Lieut.-Colonel ROGER PARKER WILSON, I.M.S.  
Officiating Surgeon-General to the Government of Bengal.  
Lieut.-Colonel CLAYTON ALEXANDER FRANCIS HINGSTON, O.B.E., I.M.S.  
Superintendent, Government Hospital for Women and Children, Madras.

#### *O.B.E. (Civil).*

EDOARD LUCIEN DE CHAZAL, M.D.  
Superintendent, Victoria Hospital, Mauritius.  
GEORGE DOUGLAS GRAY, M.D.  
Medical Officer, H.B.M. Legation, Peking.  
Dr. VICTOR RICHARD RATTEN.  
Surgeon Superintendent, Hobart Public Hospital, State of Tasmania.  
Major ALEXANDER JAMES HUTCHISON RUSSELL, I.M.S.  
Director of Public Health, Madras.  
GEORGE PADDOCK BATE, M.D., F.R.C.S.E., J.P.  
For services to the Home Office under the Factory Acts.  
DAVID MACKEY CASSIDY, M.D., D.Sc., F.R.C.S.  
Medical Superintendent, Lancaster Mental Hospital.

#### *O.B.E. (Military).*

Surgeon Commander JOHN SCARBROUGH DUDDING, R.N.  
Major JOHN SCOTT, D.S.O., I.M.S.

#### *M.B.E. (Military).*

Subadar Major BARKAT RAM, BANARUR, Indian Medical Department.

#### *M.B.E. (Civil).*

Lieutenant JAMES CHARLEMAGNE CHALKE, I.M.D.  
Assistant Surgeon to His Excellency the Governor of Bengal.

#### *Kaiser-i-Hind Medal.*

Miss ESTHER G. BARE, M.D.  
Clara Swain Methodist Episcopal Mission Hospital, Bareilly, United Provinces.  
Miss EDITH L. YOUNG, M.D.  
In charge Palwal Mission Dispensary, Gurgaon District, Punjab.

### MEDICO-PSYCHOLOGICAL ASSOCIATION.

#### *THE MAUDSLEY LECTURE.*

The quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland was held at the rooms of the Medical Society of London on May 21st, with the President, Dr. M. J. NOLAN, in the chair. Professor G. M. ROBERTSON referred to the recent death of Dr. Gardiner Hill, and spoke in very appreciative terms of his work as medical superintendent of Middlesex County Asylum for twenty-eight years; Dr. Hill had formerly been at Lincoln and Cane Hill.

The sixth Maudsley Lecture was delivered by Dr. J. SHAW BOLTON, F.R.C.P., professor of mental diseases in the University of Leeds, and medical director, West Riding Mental Hospital, Wakefield.

Dr. SHAW BOLTON opened with a reference to the number of theories of mind which had been advanced since the war, often in ignorance of, or with scant reference to, the accumulated knowledge of the past. Incidentally, he spoke of the "Rasputin-like philosophy of Freud." The lecturer set out to give an account of the present knowledge on mind and brain as established by fact, as opposed to preconception and theory. Purposeful action was, he said, merely action for a purpose, and not action based on intent by the agent; he objected to the attempt to "anthropize" the actions of the lower animals. He entered into a long dissertation on the origin and behaviour of insects, birds, and mammals, showing that the two latter were comparatively late comers, mammals having only begun to rise in size and degree of evolution about two million years ago. Civilized man appeared to date from 6,000 years ago. Dr. Bolton proceeded to demonstrate, as the

Annual Dinner  
of the 200

The annual dinner of the association, which was attended by more than 300 members, was held at the Hotel Cecil on Saturday evening, Mr. Badcock presiding. In responding to the toast of "The Imperial Forces," Surgeon Vice-Admiral J. Chambers, Medical Director-General R.N., remarked that the Navy had now only forty-eight dental surgeons, but he hoped to see both the number increased and the conditions of service bettered in the near future. Air Commodore D. Munro, Director of Medical Services, Royal Air Force, who also responded, said that at present the dental service of the Army was shared by the Air Force. He remarked that the effect of the school dental service was beginning to tell in the higher dental standard of the recruits now coming forward. The toast of "The British Dental Association" was proposed by Mr. L. G. Brock, principal secretary of the Ministry of Health, who said he had been struck by the increasing realization on the part of all those associated with National Health Insurance of the importance of securing adequate dental treatment for the insured population. The evidence before the Royal Commission, not only by dentists but by doctors and dental treatment societies, had shown the necessity of providing dental treatment as complementary to medical and surgical treatment. Sooner or later statutory dental benefit would come about. The toast was responded to by Mr. Norman Bennett, who commented upon the more critical frame of mind which had possessed the rank and file of the association in recent years. Mr. A. T. Pitts proposed the health of the guests, and there were replies by Professor William Wright, dean of the London Hospital Medical School, and Dr. A. L. Hipwell.

*Papers and Discussions.*

The papers read at the meeting included "The histology of enamel caries," by Mr. H. C. Mallison; "A sixteenth century account of the teeth and its influence on the growth of the temporomandibular joint and its influence on the growth of the mandible," by Mr. S. Wilson Charles; "The use of ultra-violet rays in dentistry," by Mr. A. E. Rowlett and Mr. Ivan S. Spain; and "The problem of orthodontic treatment for children in the elementary schools," by Mr. B. B. Samuel.

tion for possible future function. The actual results of sensory stimulation were recorded in a largely time-related manner in the various projection areas and zones, with varying degrees of definiteness. It was also recorded through words and verbal complexes, chiefly the visual. Also, and very importantly, the language mechanism was employed in the recording of what was known as "learning by heart." Dealing next with recollection, he said one of the agents of memory was the activity of the cerebrum generally, by which a series of sensory images were recalled owing to certain of the activity of another, or having formerly been stored in the activity of some time or place, or both.

[illegible]

Although cerebral day-dreaming at the considered it passive, and then it was replaced by instinctive or purposeful behaviour, and the instincts instead of being paramount, now served as modifiers of cerebral activity, inducing the best—or the worst—and preventing stereotypism and habit. The whole purpose of education and training was to evolve reasoned purposeful action in place of instinctive reaction to environment. The best example of man's racial immaturity was mental disease. On one side of the scale there were all grades of subevolution of the cerebrum, mental counterparts, ranging from the gross idiot, through feeble-mindedness, to the unstable and occasionally insane. On the other side were various grades of insanity, from the most durable and dissolved cerebrum, through the transiently durable and dissipated cerebrum, to the grossly degenerated and dissolved cerebrum, which might provide a gloomy outlook, but truth always lies in the way ahead. Even though they had to care for their failures because they could not cure them, much could be done to lessen their severity by the employment of suitable mental measures, and under a broader conception general measures, and under a more suitable to the race.

Bolton said that at the present time they were swayed by an exacerbation of world hysteria by the myth of Freud's theory of dream interpretation. He regarded as the unconscious the "unconscious," and he had not yet encountered the lecturer considering the work, was

Dr. Shaw Bolton might be established more suitable to the  
discovery of what he regarded as the myth of the unconscious  
mind, which was based on Freud's theory of dream interpreta-  
tion. No two dream analysts were likely to lut upon the  
same interpretation, and he had not yet encountered an attempt  
to define the "unconscious mind."  
In conclusion, the lecturer considered that the future, in the  
light of sincere work, was bright with hope, for, in the words  
of John Milton :

"Where there is much desire to learn, there  
be much arguing, much writing, many  
good men it but knowledge in the  
Sum, a cordial vote  
for his lecture.

“Where there is much desire to learn, there of necessity will be much arguing, much writing, many opinions; for opinion in good men is but knowledge in the making.”

On the proposition of the PRESIDENT, seconded by Dr. FERRY SMITH, a cordial vote of thanks was passed to Dr. Shaw Bolton for his lecture

There were also a number of table demonstrations at the Central Hall, and clinical demonstrations at the Royal Dental Hospital. The latter included two demonstrations of "block anaesthesia"—one by Mr. F. St. J. Steadman and the other by Mr. F. N. Doubleday.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

THE meeting of the Royal Commission on May 25th was occupied with the evidence of Lord Sandhurst, a Lord Chancellor's Visitor, and Mr. G. M. Hildyard, K.C., Master in Lunacy.

LORD SANDHURST, who said that he was appointed to the post in 1910, described the class of cases in which a visit was directed by the Master in Lunacy. The visits were made to such cases as gave the Lord Chancellor concern on account of their difficulty. Most of the cases were those of persons with some means, and usually were paid to private houses. The number of special visits he paid by request from April, 1924, to April, 1925, was 234. Many of the persons concerned were suffering from some form of senile decay, though the subsection of the Act under which he was empowered was often extended to include mental defectives. In institutions he found the food as good as one could reasonably expect in the circumstances, though there was necessarily a good deal of routine about the menu; complaints from the patients as to food supplied were fairly frequent. Complaints with regard to noisy and offensive fellow patients were sometimes justified, usually owing to the fact that there was not sufficient accommodation to allow of the cases being classified. As to ill treatment of patients, he did not think an assault had ever been reported to him which had been backed by credible evidence. He considered that licensed houses fulfilled a most useful function, and it was a misfortune that no new licences could be granted. The smaller institution afforded a degree of quiet and privacy of a home-like character, which would not be expected in the larger places.

MR. G. M. HILDYARD said that when a person was certified as a lunatic he could no longer protect his property, which was thus, to some extent, at the mercy of his relatives. He could not say that he had had to deal with a case of wrongful certification in which relatives had got a weak-minded, but not insane, person certified, in order to secure control of his property, but the possibility needed to be guarded against. He did not think administration by the court should be enforced until some time had elapsed, as the patient might recover from his mental disability. He also pointed out the hardship of ceasing to pay the old age pension in the case of patients resident in an asylum.

## Scotland.

### SCOTTISH SOUTH-EASTERN SANATORIUM.

A NEW sanatorium was opened on May 26th, by the Secretary for Scotland, Sir John Gilmour, at East Fortune, Haddingtonshire. This sanatorium is a combined enterprise by the seven south-eastern counties of Scotland in the attack upon tuberculosis, and the new sanatorium has been constructed by the conversion of an aerodrome used during the war. The scheme originated before the war, and part of the new sanatorium has been in use since December, 1922. The full capacity of the buildings is 199 beds, which are now all available for use. The beds are allotted to the seven counties in proportion to their participation in the scheme, as follows: Berwickshire 16, East Lothian 32, Midlothian 57, Peeblesshire 10, Roxburghshire 15, Selkirkshire 13, West Lothian 56. The sanatorium lies in an open stretch of country between Berwick Law and Traprain Law, and has cost approximately £160,000, to which the Government made a capital grant of £35,820, at the rate of £180 a bed. In the sanatorium the officers' mess has been converted into a block accommodating fifty children. The blocks for male and female patients are separated, and there are x-ray rooms with special electric power station and sewage works. The ground extends to some 515 acres.

### RETIREMENT OF GLASGOW MEDICAL OFFICER OF HEALTH.

The resignation of Dr. A. K. Chalmers, M.O.H. for Glasgow, was intimated on May 27th at a meeting of the Corporation Health Committee. His retirement takes place

under the superannuation scheme at the close of the present month, after a connexion with the administration of public health affairs in Glasgow during the past thirty-three years. The committee decided to recommend the corporation to appoint Dr. A. S. Macgregor, senior divisional medical officer, as interim M.O.H. for the city.

### PUBLIC HEALTH LECTURESHIP IN EDINBURGH.

A committee of Edinburgh Town Council has had under consideration a proposal made on behalf of Edinburgh University in regard to combining the lectureship in public health with the post of medical officer for the city. At present candidates for a diploma in public health receive practical instruction in the organization and working of departments connected with the public health services of the city, and the university desires to extend these facilities to the teaching of undergraduates. The most obvious method of securing this is that the instruction should be given by the M.O.H. for the city, and the arrangement suggested is that the M.O.H. for the city should become a regular member of the University teaching staff for a course of some twenty meetings. The proposal has divided opinion in the committee of the town council which has considered it. The unfavourable view in regard to this matter is partly based upon a belief that there would be difficulty in finding time for the medical officer to undertake new duties, in view of the large demands already made upon him under his whole-time appointment. There are many who consider that if the university is to have any voice in the appointment of the medical officer of health for the city this would be unfortunate, for the association of the university with the Royal Infirmary in making appointments to the staff of the latter has not in the past proved in every case satisfactory.

### DR. EDWARD CARMICHAEL.

On the occasion of his retirement from practice, Dr. Edward Carmichael, Edinburgh, was entertained at a complimentary dinner in the Caledonian Station Hotel, Edinburgh, on May 27th, by a gathering of about sixty persons, over whom Lord St. Vicens presided. The chairman, in proposing the toast of "The Guest," referred to Dr. Carmichael's long ministration in the medical profession, in which his unfailing sympathy, cheerfulness, gentleness, and knowledge of the practice and principles of his profession had been outstanding. They all hoped that not the least fruitful of the years of his long and laborious life still lay before him. Dr. Carmichael, in returning thanks for the honour which had been done him, said that he felt it a privilege to go out and in amongst his friends for forty years. He had always felt a dread of making false or wrong judgements, for, while in other professions and in business a wrong judgement might lead to trouble which was usually retrievable, in the medical profession an error of judgement might lead to troubles that were irremediable. He thought that such success as he had enjoyed was due to this anxiety, which had been constantly present with him. The toast of "The Medical Profession" was proposed by Mr. John Prosser, W.S., and acknowledged by Professor G. Lovell Gulland, C.M.G., President of the Royal College of Physicians, and by Sir Harold Stiles, K.B.E., President of the Royal College of Surgeons.

### GLASGOW DENTAL HOSPITAL.

The annual meeting of the Incorporated Glasgow Dental Hospital was held on May 27th in the Merchants' House, Glasgow. The annual report showed that during the year the number of attendances at the hospital was 40,337, with a total of 46,138 operations. Artificial teeth had been supplied to 121 patients, the teeth having been made in the mechanical laboratory of the hospital. At the close of the year there were 136 students on the roll. The chairman, Mr. Matthew Robbin, in moving the adoption of the report and financial statement, said that the work of the hospital was not sufficiently recognized by the public. The present hospital was made up from dwelling-houses and was quite inadequate for its work, but before arranging for a site for a new hospital it would be necessary to have the prospect of money to build it.

## England and Wales.

### ASSOCIATION OF PUBLIC VACCINATORS.

THE annual meeting of the Association of Public Vaccinators of England and Wales was held at the Grand Hotel, Manchester, on April 24th. Dr. Wells (London) presided. There was a good attendance. The Council's report and financial statement were adopted. On the motion of Dr. A. E. Cope (London), seconded by Dr. Bradshaw (Liverpool), Dr. James Bennett was unanimously elected president for the ensuing year. A hearty vote of thanks was accorded Dr. Wells for his services during the past year. Dr. Bennett then took the chair, and, after expressing his appreciation of the honour conferred upon him, gave very interesting details of small-pox in Warrington, his native town, near which, at Padgate, he is medical officer of health. Striking statistics were available, the records having been well kept. In 1773, during an epidemic of small-pox there, all the deaths were in persons under 9 years of age. In the epidemic of 1892 none of the deaths were in persons under 9 years of age. Something had happened to account for this, and undoubtedly it was vaccination. The officers of the association were re-elected and three vacancies on the council filled by the election of Drs. S. C. Jones, Howe, and Johnstone from the Manchester area. Dr. A. E. Cope (honorary secretary), Dr. Drury, and Mr. J. A. Briggs (organizing secretary) were thanked for their services.

### Dual Nature of Small-pox.

At the conclusion of the formal business Dr. R. P. Garrow (medical officer of health, Chesterfield) gave an address on the dual nature of small-pox and its bearing on the vaccination question. During the eighteen months to the end of March last there had been 604 cases of known small-pox in Chesterfield. This was part of a general endemic prevalence of the disease in the Midlands of England, extending over the past four or five years. The disease had been characterized by remarkable benignity, and so far as he was aware there had been no deaths. This had led to the belief, rightly or wrongly, that under the name "small-pox" there existed two definite diseases: (1) severe and highly fatal; (2) a mild, relatively harmless disease with no mortality. Those who take this view believe that the virus of para-small-pox has in some way unknown been deprived of its toxicity, resulting in an acute specific infectious disease easily distinguishable from the parent disease small-pox and which breeds true to type. That was known as the contention of the "dualists" in this controversy. On the other hand there were those who have been described as "univists" who recognize only one form of small-pox, believing that alastrim, amara, para-small-pox, or variola minor is clinically indistinguishable from classical small-pox, and that it has indeed on various occasions reverted to the severe type. At considerable length Dr. Garrow gave his reasons for holding the "dualist" view. He summarized the clinical differences between small-pox and para-small-pox as follows:

1. Severity.—Measured by constitutional disturbance the severity in small-pox was incomparably greater; prostration never seen in para-small-pox.
2. Onset.—Lumbo-sacral pains, vomiting, and rigor replaced by more gradual onset in para-small-pox.
3. Prodromal rashes—Not observed in Chesterfield cases.
4. Haemorrhages entirely absent.
5. Small of small-pox not observed.
6. Duration of prodromal illness longer in para-small-pox.
7. Pause.—Three or four days' interval in one-third of the cases of para-small-pox between initial illness and first appearance of eruption.
8. Focal lesion.—Smaller and more superficially situated. Vesicles unilocular; evolution more rapid; suppurative often incomplete.
9. Suppurative fever.—Most often absent.
10. Exercises much less influence over
11. Absent in para-small-pox. Two cases of *eruptio profunda* observed among the Chesterfield cases.
12. Disfigurement.—Extremely rare for para-small-pox to leave behind any permanent traces on the skin.
13. Fatality.—Para-small-pox fatality is nil.

In the concluding stages of his address Dr. Garrow dealt with the vaccination question. He was convinced about the

clinical differences between small-pox and para-small-pox in the mass, and regarded the vaccination statistics of para-small-pox as furnishing equally conclusive proof of the close biological relationship between the two diseases. In the Chesterfield epidemic there was not a single case of small-pox in a revaccinated person. Of those vaccinated in infancy the youngest patient was 17 years old. From this it would appear that the protection afforded by vaccination against the mild disease is of longer duration than against virulent small-pox. Among the unvaccinated children in Chesterfield up to 15 years of age there were 277 cases of small-pox; among the vaccinated in the same age group not a single case. Continuing, Dr. Garrow said that the number of cases occurring in a house was determined, not by the sanitary state of the dwelling or the overcrowding therein, but by the number of unprotected individuals. In many of these houses every unvaccinated member of the household was attacked and removed to hospital, while every member protected by vaccination escaped. He regarded para-small-pox as more difficult to control and stamp out than small-pox proper. Vaccination afforded protection as complete and more lasting than against the virulent disease. Reasons for the difficulty were to be found in the long prodromal period and the interval between the initial appearance of the rash, making it more difficult to trace contacts. A further difficulty was occasioned by the extreme mildness of the disease causing delay in diagnosis and consequent exposure of large numbers of people to infection. In Dr. Garrow's opinion the present situation emphasizes the importance of general vaccination of the entire community in order to put an end to the heavy expenditure of public money on the hospital isolation of the disease, which is not required for the nursing of the case and which plays such a small part in its control.

A discussion followed, and Dr. Garrow was heartily thanked for his very interesting address.

### SMALL-POX IN THE COUNTY OF DURHAM.

We have received from Dr. T. Eustace Hill, medical officer of health for the county of Durham, a letter stating that he has read the leading article on the spread of small-pox, published on May 23rd (p. 574), with great interest, and expressing the opinion that every medical officer of health will agree with the views therein contained. Dr. Hill also informs us that a conference of medical officers of health and medical officers of small-pox hospitals in the county was held in Durham on May 14th. The conference was largely attended, and it was officially stated that while during the first quarter of 1925 there had been 45 cases of small-pox (of which 25 were in West Hartlepool), in the county of Durham among six sanitary districts, during the five weeks of the second quarter, ended May 9th last, there had been 41 cases in the county among thirteen sanitary districts. The present available accommodation for small-pox patients was also considered by the conference, and there was a very strong feeling expressed that in many districts there was urgent need for further accommodation. The conference adopted a series of resolutions, which Dr. Hill has since sent to the sanitary authorities and small-pox hospital authorities in the county. They were to the following effect:

1. That in view of the serious danger which at present exists of small-pox becoming epidemic in the North of England, every small-pox hospital authority should at once, in consultation with its medical officer, review the adequacy of the accommodation provided in its hospital for cases of small-pox, and, where necessary, at once take steps to provide additional beds; and that each hospital authority should at once make such arrangements as will enable it to provide further temporary hospital accommodation for cases of small-pox at short notice.
2. That the small-pox hospital authorities of the county, which have provided accommodation for small-pox cases, should at once enter into a pooling arrangement by which small-pox patients from any district in which the small-pox hospital beds are fully occupied can be at once admitted into the hospital of another district where beds may at the time be available, the full cost incurred by the hospital authority receiving the patients to be refunded by the hospital authority of the district from which the patient was removed.
3. That the importance of every small-pox hospital being provided with an efficient steam disinfecting apparatus be urged upon the hospital authorities in the county.
4. That as a temporary measure, and with a view to assisting in the detection of unrecognized cases of small-pox, the notification of chicken-pox be made compulsory in every sanitary district.

## HUMANE SLAUGHTERING OF ANIMALS.

A report on the humane slaughtering of animals has recently been presented to the Corporation of the City of London by the Sanitary Committee. It embodies a report on the work of three municipal officers whose duties are related to the question. The three are Dr. W. J. Howarth, medical officer of health, Mr. James R. Hayhurst, chief veterinary inspector of the Metropolitan Cattle Market, and Mr. T. D. Young, the Corporation's veterinary surgeon. The subject has been under consideration for some time, but the immediate occasion for dealing with it was a petition from the Council of Justice to Animals signed by their chairman, Mr. C. Lionel Hanington. That society urged that Clause 9 (u) of the Ministry of Health's model by-laws for slaughterhouses be passed by the Corporation. In the petition it was pointed out that ninety boroughs had already passed the by-law and that 623 medical consultants in London had in 1923 urged the adoption of the clause. Its terms are as follows:

"A person shall not in a slaughterhouse proceed to slaughter any animal until the same shall have been effectually stunned, and such stunning shall, except as hereinafter provided, be effected with a mechanically operated instrument suitable and sufficient for the purpose. Provided that this by-law, so far as it would require the stunning of sheep and the use of a mechanically operated instrument, shall not apply until the expiration of three months from and after the date of the confirmation of these by-laws. Provided, further, that this by-law shall not be deemed to apply to any member of the Jewish faith, duly licensed by the Chief Rabbi as a slaughterer, when engaged in the slaughtering of cattle intended for the food of Jews according to the Jewish method of slaughtering, if no unnecessary suffering is inflicted."

The three reporters have been unanimous in recommending the by-law in respect of (a) cattle, including calves; (b) horses; and (c) pigs, the flesh of which is to be consumed as fresh pork. They differed, however, concerning sheep, Mr. Hayhurst and Mr. Young advising that these be excluded from the by-law, while Dr. Howarth was in favour of their inclusion. The Sanitary Committee adopted the view of the majority, and the Council itself has concurred. As embodying the conclusions reached on this and other points by the Sanitary Committee, after conference with the Cattle Markets Committee, Dr. Howarth drafted the following resolution:

"That this committee, having considered the report of its officers on the humane slaughtering of animals, and having heard the views of duly appointed representatives of the Council of Justice to Animals and of the Union of London Retail Meat Traders' Association Incorporated thereon, and having considered the effect which the adoption of Model By-law 9 (u) would have on the work at Islington Cattle Market, is of opinion that the time is now opportune for definite regulations to be framed to control and regulate the slaughtering of animals intended for human consumption, and, furthermore, is of opinion that any additional powers in this connexion should be of general application throughout the country, and that in order to secure uniformity it respectfully submits that such regulations should be issued as compulsory regulations framed by the Ministry of Health."

This was adopted by the Committee, and became in effect the finding of the Corporation. It will be observed that to secure uniformity it is urged that the by-law should be applied throughout the country and should be made compulsory by the Ministry. The three officers in their report consider the question in detail. The first essential in satisfactory slaughtering is that there shall be efficient bleeding, because blood rapidly putrefies, especially in hot countries. Unnecessary pain must not be inflicted, time should be saved, and there should be avoidance of damage to edible parts. Various methods have been used, bleeding being effected in all of them by cutting the throat. Preliminary stunning may be done by the hammer, mallet, or maul, or by the poleaxe. Alternatively, unconsciousness may be produced by mechanically operated instruments, the mechanism forcing either a bullet or a captive-bolt through the bony structures of the head. The bullet is actuated by an explosive cartridge; the bolt by a direct blow, a spring, compressed air, or a cartridge. The reporters made observations of the effect of two instruments of the bolt-propelling type, one known as the Cash pistol and the other the Temple Cox apparatus. The conclusion reached was that an efficient mechanically operated instrument is more to be depended on than the poleaxe, even when that is in the

hands of the most skilled slaughterman. No exception could be taken to the efficiency of bleeding after stunning, and there is neither waste of time nor damage to the carcass when such an instrument is used in substitution for the poleaxe. Objections, however, have been raised to the mechanical apparatus in the case of pigs, on the ground that though the fresh pork may be all right, the use of the mechanical apparatus affects prejudicially the preparation of bacon. The reporters therefore recommend that additional information be obtained on this particular question; it has been agreed to adopt their recommendation. The Jewish method of slaughtering, which is carried out according to a religious ritual and without preliminary stunning, is described and discussed in the course of the report.

## HEALTH OF LONDON IN THE EIGHTEENTH CENTURY.

At the last meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine Dr. John Brownlee read a paper on the health of London in the eighteenth century. He first of all exhibited tables making it probable that there was a considerable influx into London towards the end of the seventeenth century, but that thereafter, down to the end of the eighteenth century, the population was almost stationary, and that the general rate of mortality (making allowance for the ageing of the immigrants at the end of the seventeenth century) also changed very little. In a general way there was not much difference between eighteenth century London and the most unhealthy urban area in the nineteenth century for which a life table had been constructed—namely, Manchester township. Dr. Brownlee called attention to the increased proportional mortality from phthisis which the London bills exhibited, and concluded that there was probably a real increase of phthisis in the last decades of the eighteenth century. He illustrated on the plague statistics of Bombay the movement in time of the maximum of an epidemic, and pointed out very remarkable changes in the seasonal incidence of mortality from convulsions and infantile diarrhoea in London. Mortality from measles was also illustrated. In opening the discussion, Dr. Major Greenwood referred to the writings of Woolcombe, Sir Gilbert Blane, Sir James Clark, and Farr on the alleged increase of phthisis at the beginning of the nineteenth century. Blane's remark (made in 1815) that "consumptions have been observed to be more frequent of late among young adults, probably from a greater number of sickly children being saved" was of interest. Dr. T. P. Beddoes thought the timing of an epidemic of plague was mainly dependent on the date of movement of stocks of grain. Sir George Buchanan wondered whether the nomenclature of diseases in the bills was sufficiently satisfactory for comparisons. The discussion was continued by Dr. A. K. Chalmers, Dr. John Carswell, and the President (Dr. John C. McVail), who all congratulated Dr. Brownlee on the great value of his contribution to the history of mortality in London.

## WESTMINSTER HOSPITAL.

The work of the department of pathology and bacteriology at the Westminster Hospital has considerably increased since its reopening last July. An offer of £20,000 has been received from Mr. A. J. H. Carlill towards the endowment of a Carlill chair of pathology. The House Committee, in consultation with the medical staff and representatives of the Senate of London University, have prepared a scheme for a unit of pathology, which is at present under consideration by the University and its Grants Committee. The new unit should prove to be of great practical value to the patients, medical staff, and the students. The hospital at present has an overdraft of £15,000 on the maintenance account, and as soon as this has been extinguished an effort will be made to obtain funds for research work, particularly in connexion with cancer. The hospital at present possesses no radium, and this handicap will be removed as soon as possible. The number of patients treated in the wards since the hospital reopened is 2,786, as compared with 2,173 for the corresponding period of 1922-23. The out-patient figures have increased by 35 per cent.

# Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

AMONG Acts to which Royal assent was given before the House adjourned for Whitsuntide were the Protection of Birds, Rent and Mortgage Interest (Restrictions Continuation), Imperial Institute, and Poor Law Emergency Provisions Continuance (Scotland) Acts.

The House of Commons will be occupied with the Committee stage of the Finance Bill for the whole of next week after reassembling on June 9th. The Public Health Bill and the Rating and Valuation Bill will be considered in Grand

## Ministry of Pensions Debate.

During the debate on the Ministry of Pensions vote for £66,026,000, the Minister, Major Tryon, estimated that in 1925-26 medical treatment and services would cost £2,847,000, compared with £3,559,000 in the previous year. It was a declining charge because, reaching a stability where normally no further treatment was likely to be wanted. The death rate among disabled men remained fairly stationary at about 13 per 1,000 annually, a rate about the same as that of the general population. The number of cases in which there was such an improvement in the disability as to warrant a reduction in the rate of compensation was necessarily diminishing. Last year in 17 per cent. of the cases examined there was a reduction in pension and in 26 per cent. an increase. On the pensions list at present there were 615,000 officers and men, of whom more than half had received final awards and were relieved from the trouble of medical re-examination. The majority of men on the pension list had been found to be steadily improving in health, thanks above all to medical treatment, and had been pursuing normal occupations at a normal wage, except so far as they were affected by industrial depression. The Minister defended the system of final awards, saying that they did not imply recovery or that there might not be some slight fluctuation up or down, but that they meant that a condition of normality had, in medical judgement, been reached. The Ministry took the highest professional medical advice in regard to each kind of disablement, and in accordance with that advice the final award of disablement, and 100,000 men who had received final awards, less than 20 per cent. had appealed, and in only 5 per cent. of those appeals did the Medical treatment become the medium through which error, if any, in a final award was disclosed. The mere fact that medical treatment was necessary after a final award did not mean that the award was wrong. But where treatment showed that the diagnosis of the case had been faulty or the prognosis had been wrong, and the error had involved a serious underestimate of the man's disablement as a permanent matter, the Minister was able to recommend the case for further compensation. Major Tryon announced that he and his predecessor, Mr. F. O. Roberts, had co-ordinated with that advice the seven-year limit on claims for pensions, and said that a claimant for pension was asked to do no more than get some account of his past medical history from his panel doctor or his approved society.

In moving the reduction of the vote by £100, Mr. F. O. Roberts referred to the treatment of men in training centres and thought that from the medical view it had been a mistake to take these centres away from the Ministry of Pensions. He urged closer co-ordination with the Ministry of Health and the Ministry of Labour, particularly as regards tuberculous cases. There was always a doubt after this long period of time about the association of this disease with war service, and all sorts of difficulties seemed to crop up in the case of these tuberculous men. He paid tribute to the work done at Papworth, Enham, Preston Hall, Blackpool, Rectall, and Epsom, and said there would have to be an extension of such centres.

Mr. Macpherson said that during three years £55,000,000 had been spent on medical treatment, and the taxpayer expected to see a reduction in the cost. In regard to the time limit on claims for pensions, Mr. Macpherson said that when he was Pensions Minister his medical boards had advised him that he was Pensions Minister for a good period, but he had fixed it at seven years.

After a long explanation by Commander Astbury about a statement he made in December last, and a long argument in which gave a general exposition of the Ministry of Pensions, which, he said, had been one of the most wonderful achievements of the war. To medical science the war was as revolutionary an experience as it was to the science of warfare, and the bare magnitude of the demands made on medical science created by the war was completely without precedent. Fresh problems arose on a scale that was absolutely unknown, and the medical profession had to mobilize all its resources and all its skill in order to grapple with the many problems arising out of that memorial. At one time the medical profession met that demand with a scale of memorial to its skill and science, and many men walking about now would bear willing testimony to that memorial. Treatment for the Ministry had 113 hospitals and 650 clinics, which, when established, were a new feature in public medicine, at operative or other wounds and injuries under the Ministry did not stop short, as it often did in the case of civil hospitals, at the process of immediate treatment. The medical branch of the Ministry decided to include the whole range of orthopaedic treatment—the process of restoring nerve and muscle to the injured part. That meant the

establishment of massage and electrical treatment and the provision of curative workshops. The Ministry had run fifteen orthopaedic hospitals of its own and sixty clinics in which supplementary orthopaedic treatment was given. This class of case, had on the whole yielded better results than almost any other. Naturally the numbers were diminishing, and at present the Ministry was maintaining eight hospitals for this purpose and forty-four clinics for treatment of cases of injury. Major Stanley had protested against men who had lost their reason by war service being described as pauper lunatics. But the State insisted on them being treated as private patients. The Ministry had not provided private hospitals for these men because their relatives objected to their being removed to any distance. In neurasthenia as distinct from mental disease no pains were spared to get a man back to normal, and the experts agreed that the best cure was to get a man back to normal life and occupation as soon as possible. The Ministry had had twenty neurological hospitals and forty-eight clinics for this purpose, and had to draw heavily on the members of the medical profession who had given special study to neurasthenia and had to train a large number of specialists and restored to their normal condition. On the other hand, there were the border-line cases. The Ministry went to extreme lengths so as not to certify them, and had several establishments, the largest at Ewell, to deal with such cases. On the whole they had been exceedingly successful. They had gone further and had two establishments for certified cases—one in the north and one in the south—where selected cases were sent by agreement with the medical officers of the Board of Control. Unfortunately, the relatives of some of the most suitable cases objected to their removal to these establishments, and up to date the experiment would not justify any considerable extension. The arrangement in conjunction with the Ministry of Health to provide training for the tuberculous ex-service man after his ordinary course of sanatorium treatment had not been quite a success. A man having finished his sanatorium treatment did not care to stay away from his family for an extra year to complete his training. Now when a man was going to be discharged from the sanatorium the medical officer of health and the employment exchange manager were notified so that every effort would be made to get him some work, and, if necessary, more suitable habitation. The Ministry was spending some £20,000 a year in allowances for the tuberculous.

Colonel Stanley added that there was a slight increase in the estimate for artificial limbs, as they were replacing the old heavy limb by a lighter one which cost more but would last longer and was a far greater comfort to the men. In conclusion, Colonel Stanley said that the Ministry had spent £60,000,000 in medical treatment alone, and he declared they owed a great debt of gratitude to the medical branch of the Ministry.

Mr. Merriman said that for five years he had been an additional president over a pensions appeal tribunal. He suggested that some awards confused termination of a disability with quiescence, and gave instances where a man who suffered in warm weather from a series of colds was held, by a board in January, to have had his negrivation terminated, and a similar verdict was passed in July on a man whose rheumatism flared up in winter. He reminded that there was sometimes an undue insistence on the absence of hospital records, which were asked as confirmatory evidence that there was a disability during service. This applied to the tuberculous cases, where it was insisted that there should be a continuous history suggestive of tuberculosis dating back to within a year of the date of demobilization. The man who was in the greatest difficulty was the man who had a series of ordinary colds, influenza, and things of that sort, in regard to which he had managed to contrive that he should never be sent down to hospital. They could always get hospital records for the man who wanted to make a case. It was the man who had stuck to duty in respect of whom there was no absence of hospital records.

Mr. Pielou said it was impossible that the employment exchanges could find a position for a man suffering from tuberculous disease. The only solution was the setting up of village settlements. If members who opposed this scheme could visit Papworth and see the work carried on under Dr. Varrier-Jones their views would be considerably altered. Of the 55,000 men suffering from tuberculosis for whom the Minister had accepted responsibility, 15,000 had already gone. An interdepartmental committee in 1919 recommended the expenditure of £1,000,000 on village settlements, but only £20,000 had been spent, whereas huge sums were wasted on sanatorium treatment. The man went back to housing conditions and work which did not suit him, and was soon as bad as before.

Dr. Drummond Shiels confirmed Mr. Merriman's remarks about the doubts expressed when a man was found to be suffering from tuberculosis and there were no records of influenza or anything of that sort on his medical history sheet. It was the same with other conditions. Gastric ulcer, cancer, and cerebral haemorrhage were practically ruled out as impossible to be connected with war service. Many cases of gastric ulcer had followed digestive trouble arising from irregular feeding or foully feeding during army service. But if the man had carried on despite his indigestion, he was now told that the gastric ulcer was entirely unconnected with war service. Although it was difficult from a medical point of view to connect cerebral haemorrhage with war service, the Dr. Shiels contended that the Ministry was much inclined to stand by a technical death certificate. He had a case of a man who died after a long-standing injury of the leg sustained in the war. There was an open sore. The man was in hospital in the weeks before death. He suddenly became very ill and died in a week. There had been a young locomotive engaged in the case, and he put down the cause of death as intestinal paralysis, which was the terminal condition. To anyone familiar with

medical matters at all, the whole case spoke of septicaemia (blood poisoning) as the result of the injury to his leg. But because this young doctor had put intestinal paralysis on the death certificate—the actual and immediate but not the primary cause of death—this man's widow could not get a pension. There were many of these cases. It was rather unfortunate that medical men were employees of the Ministry. It would have been much more satisfactory had they been independent of it, because there was a tendency, unconsciously, to feel that they were appearing for the Ministry of Pensions, and that it was the Ministry of Pensions *versus* the man. Anyone who had been to an appeal tribunal, and spoken for ex-service men, must have felt that sort of atmosphere on many occasions.

Sir Wilfrid Sugden said he had gone to the trouble of obtaining details of the *proceduro* regarding medical inspection, adjustment, and entitlement in the United States, France, Belgium, Germany, and Italy. None of these countries provided for even so thorough and equitable a judgement as obtained at present in this country, both as regards committees, medical boards, the very rightful provision for ex-service men sitting on adjustment committees and pension grant committees. Major Tryon replied to the debate, and the motion for the reduction of the estimate was defeated by 279 to 149.

**Small-pox and Vaccinia Mortality.**—Sir Kingsley Wood supplied Mr. Trevelyan Thomson with the average annual deaths in England and Wales from small-pox and from vaccination by decennial periods. In 1861-70 the average was: small-pox 3,421, cow-pox and other effects of vaccination 10; in 1871-80, 5,705 and 29; 1881-90, 1,228 and 52; 1891-1900, 406 and 43; 1901-10, 429 and 19; 1911-20, 14 and 9.

**Morphine Exports.**—Answering Mr. Campbell, the Home Secretary gave details of the amount of morphine exported from Great Britain during 1924, of which practically all was of British manufacture. The export to Europe was 60,080 oz., including 7,592 oz. to Austria, 4,462 oz. to Czechoslovakia, 13,763 oz. to France, 7,481 oz. to Germany, 4,661 oz. to Holland, and 3,340 oz. to Spain. To Asia the export was 12,505 oz., including 1,688 oz. to China, 2,126 oz. to India, and 7,411 oz. to Japan. To Africa the export was 1,401 oz. To America it was 9,128 oz., including 6,042 oz. to Canada, and to Australasia 5,757 oz., including 2,899 oz. to New South Wales. The grand total of morphine exported in 1924 was 88,871 oz., compared with 98,831 oz. in 1923, 131,658 oz. in 1922, 77,364 oz. in 1921, and 322,672 oz. in 1920. A condition that the morphine should not be re-exported had not been proposed by the League of Nations and was not insisted on when the British Government was satisfied that adequate control over exports was exercised by the importing country.

## Correspondence.

### DISEASES DUE TO FASHION IN CLOTHING.

SIR,—I have read with great interest Dr. Parkes Weber's article upon this subject in the *British Medical Journal* of May 23rd (p. 960), and I support the view that a serious form of persistent cyanosis of the feet and legs may, in some cases, be an outcome of insufficient clothing.

To Dr. Drybrough-Smith of Hastings I am indebted for such an example in an athletic young lady, who herself dated the cause of her trouble from getting daily chilled from insufficient clothing. Regardless of being at that time in residence in a colder climate than that of her home, she admitted that she had foolishly persisted with her scanty garments.

It is indeed remarkable how intractable these cases are in response to treatment, and it would seem, as Dr. Parkes Weber suggests, that there must be serious damage to the capillary circulation. As a mere man, and more particularly as one who has had the honour of teaching many lady doctors, I am too cautious to reason with young ladies, but try to give them what I believe to be facts. At the moment, about ladies' clothes, there are few facts, though as a doctor one is grateful for the remarkable swiftness with which they can be discarded for medical examination.

If, however, Dr. Weber's contention proves, as I believe it to be, essentially correct, I should like to add my testimony to warn against the serious condition that results from such chilling.

It is to be supposed that such cases are exceptional, and it may be that Dr. Weber, Dr. S. Dore, Dr. A. W. Scott, Dr. H. MacCormac, Dr. G. M. Meachen, and others, including myself, are wrong; but if we are right I hope all medical women will use their great influence and remind parents, and more especially their daughters, of the fact that in cold, changeable climates, age-long experience has proved the need, in cold weather, for warm clothing. They, doubtless, will be ready to counter the instant reply, "We are not going to be stuffy old Victorians."—I am, etc.,

London, W.1, June 1st. F. JOHN POYNTON, M.D., F.R.C.P.

SIR,—I was much interested in Dr. Parkes Weber's reference, in his article in your issue of May 23rd (p. 960), to a form of chronic erythema of the legs in young women, associated with the wearing of short skirts and silk stockings, as for some time I have been acquainted with a similar case in which I had, in ignorance of previous writings, assigned a causal part to the prevalent short skirts and thin stockings. This is a chronic painful erythema between knees and ankles in a woman aged 43 years, becoming aggravated in winter, but improving very much in summer, and improving also by a rest of several days in bed. Slight superficial varicose veins are present. I had, however, differed entirely in my explanation of the causation, as I had put it down to lack of protection, not from cold, but from heat rays furnished by the ordinary domestic fire, and was supported in this view in that an afternoon in a chair close up to a good fire was always followed by an exacerbation of symptoms, while there seemed no relation to exposure to cold out of doors. The sites of maximum intensity, on the outside of the right calf and the inside of the left one, were the parts most exposed to heat rays in a person sitting in the patient's usual chair, on the right hand of the fireplace. This patient has no tendency to chilblains.—I am, etc.,

Guilborough, May 25th.

C. R. GINSON.

### VOMITING IN INFANCY.

SIR,—It is not, I think, possible to debate all the points which Dr. Parsons raises in his letter (May 23rd, p. 986) without needlessly reiterating much which was said in the lectures. The difficulties raised are precisely those which I attempted to explain.

I do not myself find it difficult to suppose that in these disorders of peristalsis in the young infant hypertrophy develops with a rapidity unknown in other conditions and at a later age. I think that I have traced the development of hypertrophy with the same rapidity in achalasia, both of the ilco-caecal valve and at the anus.

For the rest it is a difficult matter to compare the boundaries set by anatomical terms with those of function. It is clear that the contractile cylinder includes those parts of the gastric tube which have been called the "pyloric canal" and the "vestibule." An x-ray examination will often show the contractile cylinder in a phase of relaxation with a wide lumen. After death or at operation the lumen of the pyloric canal is completely obliterated, that of the vestibule remains patent.

I think Dr. Parsons must be wrong in attributing a peristaltic function to the cardiac portion of the stomach. The term "contractile cylinder" has no meaning if the whole stomach has this function.—I am, etc.,

London, W.1, May 26th.

H. CHARLES CAMERON.

### CLEAN MILK.

SIR,—Dr. Chalmers Watson has recently stated that none of the leading general hospitals or children's hospitals in this country have yet given this subject serious consideration. Presumably he refers to the large voluntary hospitals; which are still the leading hospitals in most matters connected with the technique of surgery and of curative medicine. If, however, one looks to them for a lead in matters connected with preventive medicine, one will, as a rule, be disappointed.

It must now be evident to Dr. Chalmers Watson from the correspondence on this subject that he was not quite just to local authorities and their hospitals in his original article. Even in his letter of May 17th, in referring to the recent introduction of certified milk to the Paisley municipal hospitals, he states: "So far as I am aware, Paisley has therefore the distinction of taking the lead in establishing a much needed reform." Grade A milk (Food Controller's designation) from a tuberculin-tested herd has been in use in the *Burgh Infections Diseases Hospital*, Motherwell, and the *Wishaw Tuberculosis Hospital* since March, 1922, and in the *Carnegie Child Welfare Centre* and the *Maternity Home*, Motherwell, from the

date of opening in June, 1923. I well remember that first day of the use of Grado A (tuberculin tested) milk over three years ago, when so many of the convalescent children in the fever hospital asked for a second supply of porridge, because, as they said, "they were getting cream with it."

Further, I know that the Middle Ward District of the county of Lanark arranged for a supply of Grado A (tuberculin tested) milk to its hospitals fully a year ago, and I have no doubt that other local authorities have done so also.

That it is a reasonably economical proposition is, I think, proved by the fact that my town council has just recently contracted for a year's supply at an average price throughout the whole year of 1s. 6½d. a gallon, for a fluctuating daily supply of about 40 gallons delivered at the nearest railway stations.

As to the education of public opinion on this subject—a matter also mentioned by Dr. Watson—I may say that in June, 1923, at a largely attended public meeting, the National Clean Milk Society's film, "Production of certified milk on an English farm," was shown in the Carnegie Child Welfare Centre, Motherwell.—I am, etc.,

H. STANLEY BANKS,

May 25th. Medical Officer of Health, Motherwell and Wishaw.

SIR,—In view of Dr. Chalmers Watson's admirable propaganda in connexion with supplies of clean milk, and the correspondence appearing in your columns, it appears desirable to put on record the Aberdeen position.

In October, 1924, Aberdeen Town Council gave authority for the use of certified milk in all the public health institutions of the city. These include the City Fever Hospital and Tuberculosis Hospital, Burnside Home for Mothers and Babies, Loch Street Home for Mothers and Babies, and the Charlotte Street Day Nursery. At the same time the council authorized that certified milk only should be supplied to all mothers and children obtaining milk in their homes from the Health Department, and also to all tuberculous patients similarly receiving milk in their homes.

With a view to encouraging the production of certified milk, the Aberdeen dairymen have been informed that the town council contract will necessarily be divided among dairymen retailing it. At the same time, producers of milk in the Aberdeen area have been assured that the Health Department will do everything in its power to assist them should they be prepared to supply certified milk. Thus, whenever a dairyman is prepared to supply certified milk, the Public Health Department is prepared to analyse the milk samples twice weekly, free of charge, and to send the results of the analyses, both chemical and bacteriological, to the milk producer for his guidance. The milk producers have also been informed that they will be given a period of some six months in which to adjust their production of milk, so that it meets the certified standard, without any interference from the Health Department apart from helpful advice. The milk producer who at present holds the Aberdeen Town Council contract for certified milk is using the bacteriological counts, as supplied by the Health Department, to form the basis of the bonus system on which he pays his workers. Thus, the milk counts as sent to the milk producer are posted on a notice board every week at the two farms producing the milk, for the information of the workers, who receive a bonus to their wages, descending in amount according as the count of the milk ascends from under 5,000, under 10,000, under 15,000 organisms, and so on.

When certified milk was thus introduced into Aberdeen some seven months ago, all the medical practitioners of the city were circularized, urging them to do everything in their power to get their patients to use certified milk in their households.

The wide publicity given by your columns to the matter of a clean milk supply is of the most useful description, and will, I am confident, be productive of much good.—I am, etc.,

May 25th.

J. PARLANE KINLOCK,  
Medical Officer of Health, Aberdeen.

SIR,—The correspondence in the BRITISH MEDICAL JOURNAL on clean milk, following on the article on grading of milk by Dr. Chalmers Watson in the *Scotsman*, prompts me to point out that at this sanatorium we have used certified milk or its equivalent since 1915—"equivalent" because at that time there was no official grading, but the milk was of the same high standard, and from the same farm (Storms Farm Dairy, near Keswick). We were, in 1915, about to build a dairy modelled on that at Coombe Bank, near Sevenoaks, and had calculated it would then cost us about 5d. a quart, as against the local price of 3d. Mr. J. A. Spedding, J.P., of Storms, was at the same time interested in the problem, and through his energy we were enabled to obtain the highest quality at an intermediate figure. It is of great interest to note that the bacterial content of the Storms milk has been as low as 10 per cubic centimetre.—I am, etc.,

Blencathra Sanatorium, Threlkeld,  
Cumberland, May 25th.

W. GOODCHILD.

SIR,—I am glad to learn from the correspondence in your columns and other letters that I have underestimated the number of local authorities who are encouraging the production and consumption of clean milk. The statements in my original communications were made tentatively, and were the results of definite inquiry in quarters likely to be well informed on the subject. The correspondence has revealed that, in addition to those referred to in my communication, the public health authorities in Aberdeen, Motherwell, Wishaw, Lanark, and Hawick in Scotland, and Leicester in England, have gone in for clean milk, and it is probable that the list could be extended. The additional information learned merely emphasizes the point made in my communication as to the progressive action of the public health authorities in this direction. The attitude of the public health authorities on the subject was, however, a quite subordinate part of my communication. I raised the question whether any of the leading general hospitals, children's hospitals, or maternity hospitals in this county—apart from those officially under public health authorities—had yet given the subject serious consideration, and the question applies very specially to hospitals utilized for the purpose of medical education. On this point the correspondence has not added any information.—I am, etc.

Edinburgh, May 30th.

CHALMERS WATSON, M.D.

#### IMPORTANCE OF EXPLORATORY INCISION IN CANCER OF THE BREAST.

SIR,—With Mr. Duncan C. L. Fitzwilliams's lecture on "The importance of exploratory incision in cancer of the breast" (May 23rd, p. 953) most practitioners will agree. His logic illuminates a problem that faces all of us too often. Many must share his impatience with stereotyped methods of diagnosis and prognosis—notably, perhaps, with that delusive faith in flat-hand differentiation—and one at least of his readers would have received his message in mute admiration had he chosen a title less ambiguous and defined more strictly the limits to his surgery. But cases come to mind. Let me briefly recall one. A stout, well coloured woman of about 40, consulting me about another matter, mentioned her breast. She "thought there was something there." I felt a little tumour and sent her to hospital at once. Three days later she returned to say she had been told there was nothing in the breast. She consulted a surgeon, was admitted to hospital, and underwent operation eight days after I first saw her. Her case excited some interest, for certain of the staff maintained there was no tumour. Incision revealed a growth no larger than a big hazel-nut. Still doubtful as to its nature, the surgeon cut into it *in situ*, and then at once, as it seemed malignant, removed the whole breast with some glands from the axilla. A pathologist confirmed its malignancy. Recovery was uneventful. That was in mid-March, 1908. Eight months later I saw the patient again. She had clear evidence of cancer in the lung. To relieve pleural effusion I had to aspirate five times. She died on February 2nd, 1909. There is every likelihood (a) that incision into the growth had caused metastasis, and (b) that operation on the lines suggested by Mr. Fitzwilliams would have saved her life.

But in view of these facts, and of the fact that some surgeons still incise *in situ* with an erroneous notion of sparing their consciences, I would suggest that Mr. Fitzwilliams, before he republishes the lecture, change its title to "The importance of exploratory operation in tumour of the breast," and underlines the risks inherent in opening any tumour *in situ*.—I am, etc.,

Belfast, May 25th.

ROBERT WATSON, M.D.

#### ULTRA-VIOLET LIGHT.

SIR,—It is probably true that the high amperage carbon arc affords a spectrum which most nearly approaches that of the Swiss alpine sun. That fact alone, in my opinion, renders it unsuitable for the treatment of cases of definite disease, as the necessary technique will involve daily continuous exposures of three or more hours for a period of a year, or even longer, in such diseases as surgical tuberculosis and lupus. For patients to have to sit still at a distance of three feet from an arc light for such prolonged periods puts a strain upon human endurance. In addition to this drawback is the graver disadvantage that the treatment has to be carried out in enclosed rooms, the atmosphere of which is being poisoned by the carbon monoxide and dioxide gases given off by the burning carbons. No doubt such lamps have a distinct sphere of usefulness in giving prophylactic light baths.

The mercury vapour lamp has not these disadvantages. On the other hand, its fragility and varying output render it unreliable. It takes a variable time to "warm up" after starting the arc, and, until then, its output of ultra-violet rays is negligible. Also, there is a gradual deposition of metallic mercury on the inner wall of the quartz tube, which more and more, as its life proceeds, "filters" out the ultra-violet rays. Even with this lamp exposures, therefore, have to be unduly long and repeated.

The tungsten arc lamp has many advantages over other sources. Its output is far the richest in ultra-violet emanations, the spectrum showing an almost continuous band down to wave-length 180. In quantity the ultra-violet radiation emitted shows a still greater preponderance. The only variable factors—target skin distance, amperage, and exposure time—are under the control of the operator. If the shorter wave-lengths are not required all that is necessary is to increase the target skin distance, the intervening atmosphere absorbing them. The tungsten arc lamp is richer also in its luminous spectrum, and especially in the red and infra-red rays, so that there is no need, as in the case of the longer exposures required by the mercury vapour lamp, to supplement the light by the use of heat rays from some other source.

With the tungsten arc lamp I very rarely have to exceed an exposure of five minutes, and generally find that one exposure a week is all that is required. Indeed, I am quite certain that in many cases a wrong technique is adopted by giving too frequently repeated dosage. The tungsten arc can be modified also by using one electrode of carbon and one of tungsten. The tungsten arc lamp is as great an advance over the mercury vapour lamp as is the Coolidge tube over the old gas-filled tube in x-ray work—that is, for operators who desire to standardize their dosage and results.

Actino-therapy is as yet in its infancy and is but imperfectly understood. There are already too many tyros in the field, and their numbers are being added to daily. A scrutiny of an instrument maker's catalogue seems to assure some doctors that all they have to do is to purchase a lamp and turn on the switch and they are already fully competent actino-therapists. I am afraid that this belief is going to lead to disaster and bring this branch of therapy into unmerited disrepute. The skin reaction or erythema is nothing to go by. It does not indicate the constitutional reaction. I have given dozens of doses to infants and children without any skin reaction, and yet have achieved the results I desired. Similarly with pigmentation, which, more often than not, is what one wants to avoid. If pigmentation occurs too early further treatment is useless, as the pigment acts as an impervious screen to the ultra-violet rays.

The personal factor or idiosyncrasy of the patient is of the utmost importance. No two patients react alike, and

no patient reacts in the same manner to successive doses. Therefore it is of vast importance not to treat more than one patient at a time. The patient's physical and metabolic "poise" at the time of administration, the contents of the stomach and bowels, the time of day, the effect of any drugs which may be taken, are all factors of supreme importance. The effect of some drugs can be enormously enhanced or completely altered by a dose of ultra-violet light. The same applies to the collateral use of vaccines, serums, or endocrine preparations. If these things are borne in mind it is not difficult to realize why there seems to be differences of opinion as to the use and effects of ultra-violet rays between various authorities.

I would take this opportunity of warning the profession in the strongest possible terms of the danger of allowing patients to receive this treatment at the hands of any other than the most experienced operators. Never should nurses or other lay persons be allowed to give the treatment save under direct expert medical supervision and control—not even excepting such wonderfully skilled lay operators (as one is assured in the advertisements) whose services appear to be retained in the bath establishments of some of our spa resorts.—I am, etc.,

FRANK HALL, M.R.C.S., L.R.C.P.Lond.

London, W.1, May 16th.

#### HARVEY MEMORIAL AT HEMPSTEAD.

SIR,—In his letter in the JOURNAL of May 8th (p. 905), Mr. Hopo Grant points out that a subscription of 2s. 6d. from every British practitioner would be sufficient to finance the project of rebuilding the tower of Hempstead Church, in memory of William Harvey.

I doubt if it would be possible to extract 2s. 6d. from every practitioner for any object on earth—or elsewhere. On the other hand, it should be quite easy to obtain twice that sum for such an object from at least half of us.

In this little town I have had no difficulty whatever in obtaining a subscription of this amount from every one of my colleagues, and have had the pleasure of forwarding them to the treasurer of the fund. If one member in each area will undertake this simple task, the thing will be done.—I am, etc.,

Maldon, Essex, May 31st.

H. REYNOLDS BROWN.

#### MORPHINE IN PNEUMONIA.

SIR,—Many practitioners are guided more by principle than by theory in coming to the conclusion that hypodermic injections of morphine, whether modified or otherwise by atropine, should not be given in pneumonia.

Whilst in a large workhouse infirmary I had to deal with many cases of lobar pneumonia, and in the early acute pleuritic stages, where there was very severe pain, I rarely withheld this means of relief. Now if many refuse morphine in the early stages for the relief of pain, how many would give it at a later stage as a sedative, where other sedatives have failed?

As an illustration I take the case of a man of 48 with lobar pneumonia of the right base, who began to show some difficulty in sleeping about the third day, and was given 1 drachm of paraldehyde. I was away from home for three days, and was distressed on returning to find that the patient had been unable to sleep, though my deputy had given him gr. xxx of sulphonal on two successive nights. He was now restless, with a tendency to pick at the bedclothes, was semi-delirious, beads of sweat stood out on his forehead, and he had a slightly cyanotic tinge. The pulse was 120, the temperature 103.2, and the respirations 42. Still, there was no generalized bronchitis, and the extra muscles of respiration were not being called into action. The chief feature was the restlessness, and I felt that here was a case where immediate action was called for. Morphine was risky, but I made up my mind to take the risk, and gave him a hypodermic injection of 1/4 grain of morphine with atropine, which soon took effect. I called again in four to six hours, and was delighted with the decided change for the better in his appearance. He had slept well, the restlessness had gone, the pulse and respiration were better, and there was a very obvious all-round improvement. He had a morphine injection every evening till the restlessness disappeared, and he made an excellent recovery.

I quote this as one case, but in many instances I have given it at the fourth or fifth day when there was restlessness which I felt no other drug could control. I know that this is in accordance with the teaching of many eminent authorities, but I also know that many doctors have a

rooted objection to sedatives on principle; and it is very possible that more patients die from withholding than from administering sedatives.

I make no reference here to acute bronchopneumonia, or to lobar pneumonia with generalized bronchitis, where the extra muscles of respiration are being called into action, and I assure critics that I give morphine injections only after much searching of heart, and then to none but adults.

The actions of opium and morphine are in themselves uncertain. We know that some patients merely sleep under their influence, whilst to others they bring excitement and a definite stimulation.—I am, etc.,

Middlesbrough, April 20th.

JOHN M. MACPHAIL, M.D.

#### FRACTURE OF BOTH PATELLAE BY MUSCULAR ACTION.

SIR,—On seeing a case of simultaneous fracture of both patellae by muscular action reported in the *BRITISH MEDICAL JOURNAL* of May 30th (p. 1006), I thought it would be interesting to record a similar case which happened in my practice in the winter of 1903. A lady, aged 62, was walking quietly home from church on Sunday evening, when she stumbled and fell, not being able to rise. On getting her home I found transverse fracture of both patellae, which were wired by the late Mr. R. J. Pye-Smith of Sheffield. She went on quite well for a month, when she suddenly died of syncope.—I am, etc.,

Chesterfield, May 30th.

W. M. CUMMINS, L.R.C.S.I.

#### Obituary.

##### JAMES PATRICK ANDREW WILSON, F.R.C.S. Ed., D.P.H.,

Formerly Principal Medical Officer to the Government of Johore.

WITH the death of Dr. James Patrick Andrew Wilson, on May 8th in a York nursing home, there passed away one of the pioneers of Western medicine in the native States of the Malay Peninsula. Dr. Wilson was born in 1853 in Edinburgh, where he received his medical education; he obtained the diplomas L.R.C.P. and L.R.C.S. in 1882, the F.R.C.S. in 1892, and the D.P.H. in the latter year also. After some experience of general practice in Scotland, he went to the Far East as physician to the Sultan of Johore in 1885. He immediately set himself to organize a system of hospitals and dispensaries throughout that State, and his system became a model for the other native States in Malaya. He himself during many years was one of the best known and most highly respected members of the medical profession in the region having its centre in Singapore and the Straits. His holidays at home were spent in efforts to keep his knowledge up to date. In 1898 he retired from Johore, and commenced practice in Paisley, where he lived for seven years. In 1905, at the urgent request of the new Sultan of Johore, H.H. Ibrahim, he returned to that State as principal medical officer to the Government of Johore, and shortly afterwards the Sultan conferred on him the honour of knighthood ("Dato") of the Order of the Crown of Johore—D.P.M.J. After thirty years' service in Johore he returned finally to this country in 1920, and, hoping to continue his professional work, accepted the appointment of medical officer to Blackford Parish in Perthshire. Ill health, however, did not allow him to carry this on for more than a year or two, and he retired to his native city of Edinburgh. In his early pioneering days he suffered much from malaria, and in his later years he developed symptoms of sprue. Dr. Wilson was a very lovable man, and messages to his widow and family from the Sultan of Johore and from members of his family and council, as well as from many personal and professional friends in the Far East, testify to the honour and respect in which he was held in the region where he did so much to initiate and organize both the treatment of disease and a public health service.

##### THE LATE DR. C. B. KER.

PROFESSOR BERRY of the University of Melbourne writes as follows: Notwithstanding that the exigencies of geographical remoteness render my personal testimony to the memory

of the late Dr. C. B. Ker a somewhat tardy tribute, loyalty to a dear dead friend demands it. To have known Claude Ker at all is a privilege; to have known him as I knew him—intimately, personally, and associated in a friendship such as falls to the lot of few men—is a priceless gift beyond verbal expression. Ker was a loyal soul: loyal to the honourable profession to which he was so proud to belong; loyal to the venerable city which he loved so well; loyal to his Alma Mater, of whose reputation none was so fearlessly jealous; and loyal, as are few men, to his friends. Dr. Ker's professional reputation as a world-wide authority on his chosen subject, infectious diseases, is firmly established by his writings and vast clinical experience in every medical school in the British Empire and beyond it, and will long outlast the few fleeting years of his life. But it was Ker the man, the delightful companion in leisured idleness, the keen lover of literature, the student of history, the learned Napoleonic scholar and collector, the wise and witty counsellor and friend—these it was which so endeared Ker to his intimates. Some few there are who will remember with affection and a quiet sense of humour those "football lunches" of his younger struggling days, those ever memorable meetings of the "fever board" held at the most unorthodox hours, those strenuous nights of travail which gave birth to the Edinburgh Royal Infirmary Residents' Club. Still fewer are there who will remember, as long as life lasts, Ker's truly happy and inspired moments at the Octagon—those few who bore him, with a proud mien and a sorrowing heart, to his long last resting place. Distance alone prevented a full meeting of the brotherhood. By these, at least, will Claude Ker long be mourned as friend, brother, genius, and gentleman. Like his beloved hero of fiction, he too has answered—*Adsum*.

Mr. WILLIAM PERCY BLUMER, who died on April 12th in his 71st year, was the eldest son of the late Dr. Luke Blumer of Monkwearmouth. Mr. Percy Blumer received his medical education in Edinburgh, where he obtained the diplomas L.R.C.P. and S. and L.M. in 1876, and the F.R.C.S. Edin. in 1884. He was elected honorary surgeon to the Monkwearmouth Hospital in 1884, and in 1894 he joined the honorary surgical staff of the Royal Infirmary, Sunderland, where he remained until he retired in 1914 under the age limit. He was also honorary surgeon to the Durham County and Sunderland Infirmary. In 1914 he came to London and began practice at Muswell Hill; he retired about six months ago owing to ill health. He contributed numerous articles on surgical subjects to the *BRITISH MEDICAL JOURNAL* and other periodicals. G. B. M. writes: Percy Blumer was a most lovable man, who endeared himself to his patients and a large circle of friends. He was always ready to help a friend or colleague at any hour of the day or night. He was keenly interested in missionary and temperance work. He leaves a widow and two daughters, for whom much sympathy is felt; his only son was killed in the war.

#### Universities and Colleges.

##### UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 29th the following medical degrees were conferred:

M.B., B.Chir.—F. M. Collins, R. E. Wilson.  
B.Chir.—N. R. Cunningham.

##### UNIVERSITY OF LONDON.

###### Lectures.

Four lectures on cardiology will be given at University College Hospital Medical School by Dr. John Hay, F.R.C.P., Professor of Medicine in the University of Liverpool, Friday, June 12th, Thursday, June 18th, at 5 p.m. on each day. Professor T. R. F.R.S., will take the chair at the first lecture. Admission is free without ticket.

Three lectures on blood and circulation from the standpoint of physiology will be given at University College, Gower Street, at 5 p.m. on each day. Professor T. R. F.R.S., will take the chair at the first lecture.

## The Services.

THE following honorary appointments to H.M. the King are announced:

### To be Honorary Physician.

Indian Military Forces: Colonel A. A. Gibbs, I.M.S., vice Major-General J. Jackson, I.M.S., retired.

### To be Honorary Surgeons.

Colonel E. C. Montgomery-Smith, C.M.G., D.S.O., T.D., vice Colonel F. Kelly, C.B.E., T.D., retired.

Indian Military Forces: Colonel E. L. Perry, I.M.S., vice Colonel F. Wall, I.M.S., retired.

## DEATHS IN THE SERVICES.

Lieut.-Colonel Charles Henry Bennett, Madras Medical Service (ret.), died on January 28th, aged 71. He was the son of the Rev. T. G. Bennett of Baltimore, Brandon, co. Cork; he was educated at Queen's College, Cork, and graduated M.D. and M.Ch. in 1876. He entered the Indian Medical Service as surgeon on October 1st, 1877, became surgeon lieutenant-colonel after twenty years' service, and retired on February 11th, 1903. He served in the Afghan war in 1879, receiving the medal.

## Medical News.

THE Fellowship of Medicine announces that Sir Thomas Horder will give a lecture on June 9th, at 5.30 p.m., at No. 1, Wimpole Street, on "Some cases of fever without physical signs." Three courses continue during the month—namely, in dermatology at the St. John's Hospital, in venereal diseases at the London Lock Hospital, and in tropical diseases at the London School of Hygiene and Tropical Medicine. From June 8th to 27th will be held a course in gynecology at the Chelsea Hospital for Women. The Victoria Park Hospital will hold a fortnight's course dealing with diseases of the heart and lungs, from June 8th to 20th. From June 22nd to July 4th an intensive course has been arranged by the London Temperance Hospital in general medicine, surgery, and the specialties. In July there will be courses in cardiology at the National Heart Hospital, in diseases of children at the Queen's Hospital; in neurology at the West End Hospital for Nervous Diseases, and in urology at St. Peter's Hospital for Stone. Further information about these courses may be obtained from the Secretary of the Fellowship of Medicine, No. 1, Wimpole Street, W.1.

A LECTURE on the sources of the fruit and vegetable supply of London will be given by Sir Daniel Hall, K.C.B., F.R.S., in the Chelsea Physic Garden, Swan Walk, Chelsea, on Thursday, June 11th. The gardens will be open to inspection at 4.30 p.m., and the lecture will be given at 5.15, with Sir William J. Collins, K.C.V.O., M.D., Chairman of the Chadwick Trustees, in the chair.

DR. W. E. THOMAS of Ystrad Rhondda is to be the guest of the County of Glamorgan Panel Committee, of which he is chairman, at a banquet at the Royal Hotel, Cardiff, when he will be presented by the medical practitioners of the county with his portrait in oils in recognition of his many services to the profession.

DR. G. F. BUCHAN, M.O.H. Wiltshire, has been elected President of the Society of Medical Officers of Health for the session 1925-26. He will take office in October next.

THE Board of Education has published a list of certified schools, recognized institutions for the training of blind, deaf, and physically defective students, and of the nursery schools in England and Wales. Particulars relating to the average attendance at each of the schools in the year 1923-24 are included, and the addresses of schools are shown in every case when not self-evident. The list may be obtained from H.M. Stationery Office, Adastral House, Kingsway, W.C.2, price 1s., postage 1d.

THE new buildings of the University of Bristol will be opened by H.M. the King, accompanied by the Queen, on Tuesday, June 9th.

HARROGATE Corporation has issued a new pamphlet, with many illustrations, dealing briefly with the advantages of the spa and the many interesting places in its neighbourhood. The handbook may be had free from the Director, Publicity Department, Royal Baths and Wells, Harrogate.

THE new maternity hospital of the Northumberland County Nursing Association's Training Centre for District Nurses at Willington Quay will be opened on Saturday, June 13th, at 2.30 p.m., by Lady Victoria Percy.

AN obituary notice of Sir Clifford Allbutt appears in the May issue of the *Norsk Magazin for Lægevidenskaben*, signed by the editor, Dr. F. G. Gade.

THE R.A.M.C. memorial scholarship and exhibition have been awarded by Cheltenham College as follows: scholarship, £50, W. Blackwood; exhibition, £40, J. Poë.

THE eleventh International Congress of Hydrology, Climatology, and Geology will be held at Brussels from October 1st to 15th.

AN executive committee for organizing medical congresses in Latin countries has recently been formed with Professor Charles Richet as president and Professors J. L. Faure, Gley, Hirtzmann, Roger, and Vidal as vice-presidents.

UNDER the name of *Journées médicales de Toulouse* a medical congress will be held at Toulouse from July 11th to 14th, when the following papers will be read: microbe lysis, by Professor Bordet of Brussels; biology of gynaecological endothermy, by Professor Recanens of Madrid; pathology of so-called intestinal infections, by Professor Sanarelli of Rome; the trend and destiny of surgery, by Dr. Dartigues of Paris; treatment of cancer of the cervix, by Professor Fanno of Paris; the sanitary service in occupied Germany, by Inspector-General Jacob; the bismuth treatment of syphilis, by Dr. Leyndt; the role of surgery, radium, and x-rays in the treatment of cancer of the uterus, by Dr. Regaud of Paris; the internal functions of the lung, by Professor Roger of Paris.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2.

THE TELEPHONE NUMBER of the *British Medical Journal* is **MUSEUM 9861**. The telephone number of the *British Medical Association* remains, until further notice, **Gerrard 2630** (internal exchange).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London.*

MEDICAL SECRETARY, *Mediscera Westrand, London.*

The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Daicillus, Dublin*); telephone: 4737 (Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*); telephone: 4361 (Central).

## QUERIES AND ANSWERS.

### THUNDERSTORMS.

"G" writes: In reply to "X" (May 9th, p. 903), I suggest that Mallock-Armstrong ear plugs (sound destroyers) be used and a handkerchief laid over the eyes. Thus sight and sound would be excluded. The plugs were much used during the war.

### INCOME TAX.

#### Partnership—Motor Expenses.

"C." and "E." are in partnership, on the basis that the profits are shared in the ratio of two-thirds to one-third, but each bears his own motor expenses. "E." apparently purchased his share in January, 1924, from C., who had previously not had a partner.

The division of the partnership assessment should be such as to leave each partner to bear the tax applicable to his share—two-thirds or one-third—of the average profits, less the motor expenses incurred in earning that share of the profits. The method adopted by the Inspector of taxes does not seem to us reasonable. He has deducted from the share of the average profits the average expenses actually incurred in the practice by each partner respectively. The effect as regards the junior partner is not fair, because he receives no allowance for the expenses which were incurred in the two earlier years of the three years' average by the senior partner, then acting as sole proprietor of the practice. In our opinion one-third of the expenses incurred in those years should, for the purpose of the division between the partners, be allocated to the calculation of the average expenses applicable to "E.'s" share. It may

perhaps be worth while pointing out that on the figures given the amount of the tax would be the same under either method, so that the point hardly seems to be one which particularly concerns the inspector of taxes.

#### Average for Assessment.

"FAIRPLAY," who has had a practice for many years, took a partner as from April, 1924, and the practice subsequently increased considerably. The inspector of taxes insists on discarding the three years' average, substituting for 1925-26 the basis of the 1924-25 receipts.

"We know of no legal justification for this attitude—assuming, as we do, that the partner brought in no local connexion. That, as a result of the new arrangement, increased profits were earned is not of itself a justification for departing from the three years' average. The amount of profits assessable is the average amount of the profits of the practice over the three previous years.

### LETTERS, NOTES, ETC.

#### PAPULAR RASH BEFORE ONSET OF MEASLES.

DR. DANIEL HUGHES (Bristol) states that during a severe outbreak of measles he noted in the majority of cases a papular rash on the face before the ordinary rash appeared. The papules were very small and whitish. There was no malaise and no eye symptoms, and the temperature was normal. From four to six days later the true measles rash appeared. The papular rash was so characteristic that when he saw it he could be confident that true measles would appear; he was therefore able to take all precautionary measures. The papules, which were always confined to the face, did not resemble any of the described prodromal symptoms.

#### SPUTUM EXAMINATION BY THE COLOUR BLIND.

DR. CONSTANCE S. STEELE (Ransom Sanatorium, Notts) writes to recommend a method of staining sputum (Schädel's modification of the Ziehl-Neelsen test), so as to render tubercle bacilli visible by the colour blind. A concentrated solution of methyl violet in alcohol is prepared, and 1 part of this filtered is added to 9 parts of a 2 per cent. solution of carbolic acid in water. The film is flooded with this solution and heated till steam comes off. The process is repeated three or four times, the stain being renewed if necessary; the film should be kept well flooded with stain. The film is then rinsed in a sharp stream of water, decolorized in a 3 per cent. solution of hydrochloric acid in alcohol until the preparation is light violet, and counterstained with Bismarck brown. The tubercle bacilli appear violet on a brown background.

#### TESTS FOR DRUNKENNESS.

DR. A. WITHERS GREEN (Hobart, Tasmania) writes: For many of my earlier years, perhaps twenty-five out of the forty-one, in the City of London I used to be called in by the police. In extreme cases, especially women, there is little difficulty in coming to a conclusion. In doubtful cases I used to ask the inspector in charge to let me be alone with the man in his private room. My object was to let the man's brain work uninterruptedly under the alcoholic stimulant. I then found that by sitting silently, almost unconsciously to him, at his side, not in front of his eyes, with no stimulus of sound, touch, or sight, he would begin to chatter nervously with confused ideas, and articulation; walking about, and then, after a few minutes, trials in the general room of the police station, he would be awake to be useless for diagnosis. Every minute the poison is evaporating by skin and mucous membrane—often by vomit and urine as well. I used to complain that I was frequently sent for quite an hour after arrest; meanwhile, quietness, draughts of water, and perhaps a little food, had to some extent sobered the man. The disease existed along with alcohol. The letter of Dr. Graham Grant (BRITISH MEDICAL JOURNAL, February 28th, p. 427) confirms my experience. The test which does not seem to be so reliable is the relaxation of the muscles—the relaxation of the excitant. The test of undisturbed solitude revealed the true position.

#### SMALL-POX AND VACCINATION ABOARD SHIP.

DR. A. A. RAIL (surgeon, s.s. *Sardinia*) writes: We sighted a Chinese junk in distress, two days out of Hong-Kong, on February 21st, 1925, at 11 a.m.; it had lost its rudder and become unmanageable; 144 Chinese were rescued. One Chinaman was crushed between the in the isolation hospital small-pox rash. The five Chinese with a temperature ranging from 100° to 104° F., furred tongue, shotty rash, especially thick on the face, umbilicated, present on the palate, and especially on the extremities, palms, and soles. There was not much constitutional disturbance. It was diagnosed by Dr. Barnes and myself as variola. The other 133 Chinese were placed on the poop deck and isolated. On February 22nd the number of variola patients in hospital was 144. The rash was more marked. Dr. Barnes and I vaccinated 14 new cases (one haemorrhagic), making a total of 21; all were isolated. On February 24th 23 small-pox patients and 115 contacts were removed at 3 p.m. to

quarantine station at Singapore and the ship proceeded alongside, after being fumigated fore and aft. The crew (160) were all vaccinated and 15 of the passengers. We escaped any small-pox infection and arrived at Bombay safely, all the crew and passengers in good health.

#### A CURIOSITY OF ETYMOLOGY.

TULARAEMIA, a disease so far, save for a few cases in laboratory workers, peculiar to certain parts of the west of North America, is due to *Bacterium tularensis*. This organism was discovered in 1912 by McCoy and Chapin, and shown to be the cause of a fatal epidemic among the ground squirrels in Tulare County, California; the county was so named because that region was once covered with extensive marshy beds of the reed tula, a large variety of bulrush. The disease might, therefore, by a stickler for English terminology, be termed the bulrush blood disease.

#### "WHAT CHIROPRACTIC REALLY IS."

*Tarrago from Fargo.*

THE *Journal of the American Medical Association* has unearthed the following specimen of chiropractic oratory from an advertisement published in Fargo, N. Dakota:

"We chiropractors work with the subtle substance of the soul. We release the prisoned impulse, the tiny rivulet of force, that emanates from the mind and flows over the nerves to the cells and stirs them into life. We deal with the magic power that transforms common food into living, loving, thinking clay; that robes the earth with beauty, and hues and scents the flowers with the glory of the air.

"In the dim, dark, distant long ago, when the sun first bowed to the morning star, this power spoke and there was life; it quickened the slime of the sea and the dust of the earth and drove the cell to union with its fellows in countless living forms. Through aeons of time it stilled the fish and winged the bird and tamed the beast. Endlessly it worked, evolving its forms until it produced the crowning glory of them all. With tireless energy it blows the bubble of each individual life and then silently, relentlessly dissolves the form, and absorbs the spirit into itself again.

"And yet you ask, 'Can Chiropractic cure appendicitis or the flu?' Have you more faith in a knife or a spoonful of medicine than in the power that animates the living world?"

#### SLEEPLESSNESS.

DR. A. S. DUTTON (London, N.I.) writes: In regard to "Scot's" remarks on sleeplessness in the *JOURNAL* of May 30th (p. 1026), it seems to be questionable whether he takes an entirely accurate view as to what may be called insomnia—at any rate, in his own case. A man between 40 and 50 who sleeps soundly from 10.30 p.m. to 4 a.m.—that is, five and a half hours—has had a fairly good spell of oblivion. What "Scot" appears to need is a somewhat later hour for retiring, say 11.30 p.m., and if he then sleeps until about 5 a.m. there can be little occasion for dissatisfaction, especially when this is followed by some peaceful dozing. While six hours' sleep has been said to be sufficient for a man, some of those concerning whom material has been writ large in lines of remembrances were apparently content to rise soon after 5 a.m. without experiencing harmful effects from the habit.

DR. W. L. DICKSON (Brighton) writes: The letter signed "Scot" on the subject of sleeplessness interests me greatly, as I was afflicted with a precisely similar condition four years ago. By a long course of treatment I think I may say I am completely cured, but only recently did I feel myself out of the wood, as, at intervals of a month or so, the trouble returned for one night at a time. I believe the condition to be due to pressure of the splenic colon on the solar plexus, due to flatus or collection of contents in that part of the gut. I imagined myself free from indigestion, but found that it was really the cause, though quite a different kind from the usual stomach indigestion. If "Scot" will communicate with me I will give him a full history of my case and my means of curing it.

#### COFFEE AND SLEEPLESSNESS.

LIEUT.-COLONEL C. H. REINHOLD, I.M.S., writes: From personal experience I am persuaded that insomnia attributed to black coffee only results when the cheaper brands of coffee are used, in which a large admixture of chicory or other impurity fortifies the flavour. I have found that the coffee offered at the houses of some of my friends and relations, if taken black leads to two or three hours' sleeplessness on going to bed, while the after-dinner coffee in the houses of the more epicurean, or at West End clubs and public dinners, has not had this effect. It may be suggested that, on the latter occasions, a sufficient dose of alcohol is taken to counteract this tendency, but I do not think this argument applies to the case in question. I should like to suggest that it is the impurities in post-prandial "black coffee" that produce insomnia, and that the berry *per se* has been unjustly blamed. Perhaps some of the pundits in dietetics have already settled this point, in literature that has not been available to me.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, 37, and 38 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35. A short summary of vacant posts notified in the advertisement columns appears in the Summary.

## A British Medical Association Lecture ON SOME PROBLEMS OF THYROID DISEASE.

DELIVERED BEFORE THE ULSTER BRANCH ON APRIL 30TH  
BY

ROBERT McCARRISON, C.I.E., M.D., F.R.C.P.,  
LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE.

THE problems to which I desire to direct attention relate (1) to certain causes of thyroid disorder; (2) to the influence of iodine in preventing either thyroid hyperplasia or undue accumulation of colloid material in the gland; and (3) to the types of simple goitre with which we have to deal when employing iodine as a prophylactic agent.

### CAUSES OF THYROID DISORDER.

An essential function of the thyroid gland is the manufacture, and supply to the body tissues, of a secretion containing certain active principles or hormones. This endocrine activity is generally believed to constitute the gland's sole function; but it may be doubted whether it has not some other part to play in the metabolic cycle, and whether the administration of the whole gland substance, or of its extracts, provides a complete substitute for the gland itself. Thyroxin, which contains 65 per cent. of iodine, is regarded as the chief, if not the only, active principle of the gland; but it has not yet been definitely proven that thyroxin is produced as such *in vivo*. Nevertheless, most, if not all, of the thyroid gland's activities are exhibited by this substance. Assuming that thyroxin is the gland's active principle, it may be said that the essential function of the thyroid gland is to produce thyroxin, to maintain a definite concentration of it in the tissues, and by its means to ensure a higher rate of metabolism than would exist in its absence. But it can hardly be doubted that the gland has more to do than to control combustive processes. Its anabolic activities and its regulation of the growth and repair of the body tissues are no less important. The thyroid gland is essential to the normal metabolism of iodine, a matter about which very little is known at present. It provides some substance which controls the distribution of iodine within the body and maintains a normal concentration of iodine in the blood. In the absence of the thyroid iodine accumulates in the blood, while the administration of thyroid substance restores the amount of iodine in the blood to normal limits (Hudson). On the other hand, iodine is essential to the functional activity of the thyroid gland. But it does not appear that it is essential to the functional activity of thyroxin, at least in so far as mammalian metabolism is concerned. The effects which thyroxin exercises on metabolism are, according to Kendall, independent of the iodine it contains:

"The function of iodine within the molecule is to increase the reactivity and sensitiveness of the functioning groups present, viz., carboxyl and imino; any other function of iodine is highly problematical."

There is reason to believe that besides thyroxin the thyroid produces other physiologically active substances. Thus, Kendall has extracted one which has no effect on the metabolic rate, although it contains about one-half of the total iodine in the thyroid proteins; it is mainly concerned with the nutrition of the skin and its appendages. Besides these there may be others exercising specific effects on certain organs and tissues; so that the composition of the thyroid gland's secretion is a very complex problem, and one which is far from being definitely settled. It is for this reason, and because the precise part played by the thyroid gland in the metabolic cycle is still so little understood, that the difficulties in the way of elucidating the causes of its disorders are so great. But it would seem to be fairly obvious that such disorders may be brought about by factors which interfere with the normal

elaboration of the gland's secretion or with the normal utilization of its products.

The efficient operation of the thyroid gland is dependent not only on the adequate provision of the raw materials from which its hormone-containing secretion is elaborated, but on a balanced adjustment of ions in its fluids and membranes. The composition of the food is a matter of the greatest importance to the organ, since it is from the food that it derives not only the iodine and other essential constituents of its secretion, but those mineral elements on which the balanced adjustment of ions in its fluid and membranes, and in the cell and tissue plasma of the body generally, depends. It is not enough that the composition of the food should be normal; conditions in the alimentary tract must be such as admit of the adequate absorption of all those elements and complexes which are necessary to the thyroid gland's normal operation. It is, therefore, at the threshold of absorption in the intestine that we must first seek for sources of the thyroid gland's disorder.

The second great source of interference with the thyroid gland's normal operations is disturbance at the threshold of utilization of its products in the tissues. Evidence is beginning to accumulate which suggests that the action of these products may vary at different age periods, in different individuals, and be profoundly influenced by the concentration of certain ions in the cell and tissue plasma. We are accustomed to think of thyroid disease in terms only of "hypo-" or of "hyper-" or of "dys-thyroidism"; but it seems not unlikely that the chemical constitution of the cell and tissue plasma has an importance no less than the paucity or excess or imperfect synthesis of the gland's secretion. Recently Professor Klose of Danzig placed at my disposal two photomicrographs of the thyroid gland from two subjects of "puberty goitre": the one from a case of "unmistakable myxoedema," the other from a case of "unmistakable Graves's disease"; yet both presented histological appearances typical of "primary Graves's disease." It is always dangerous to reason from structure to function, but judged by the histological features of these two specimens both appeared to be glands in active secretion, yet the one was from a case of "hypothyroidism," the other from a case of "hyperthyroidism." Might it not be that the diversity of symptoms in these two cases had its origin in some part outside the gland, and that it was due to biochemical differences in the cell and tissue plasma in these two subjects of puberty goitre? I do not say that this was so; I merely suggest that this point of view is worthy of investigation in regard, not only to puberty goitres, but to other disorders of the thyroid gland. In this connexion one is reminded that severe crises in the course of Graves's disease are sometimes associated with acidosis, and that relief may be afforded the sufferer by measures directed to the relief of the acidosis.

In regard, then, to the causes of thyroid disorder there are these two thresholds to be considered: the threshold of absorption in the intestine, and the threshold of utilization in the tissues. The medium of communication between them is the tissue plasma. Let us now consider very briefly what factors are known to interfere with the normal operation of the thyroid gland at these two thresholds, and to what extent iodine may be expected to counteract their harmful influence.

### Disturbances at the Threshold of Absorption.

1. The gland may become deranged because of the inadequate ingestion of iodine or of tryptophane. Interest at the present time chiefly centres round the former. There may be a deficiency of iodine in soil or in the water supply or in the food. Sophisticated foods, such as white flour, contain little or no iodine; while most cereals and vegetables grown on soil fertilized by artificial manures which are not of marine origin are deficient in this element. Goitre is believed to be due to this deficiency of iodine, whether it be common to all the inhabitants of certain localities or peculiar to some individuals no matter what their place of residence may be. To my mind its etiology is not always so simple as this. Nevertheless, the additional provision of iodine may in such circumstances prevent the occurrence of goitre both in man and in domestic animals. It does not, however, always appear to do so. Thus in parts of New

Zealand, where deficiency of iodine has been definitely traced to the soil and water supplies, and to the food grown on this soil, it has been found by Herens and Baker that in one locality (Timaru) the prophylactic use of iodine for a period of six months was without effect in preventing the appearance of thyroid swellings in previously non-goitrous school children. In another locality (Christchurch) its use for a period of one year reduced the incidence of first attacks of goitre in children from 55 per cent. in those who did not receive iodine to 39 per cent. in those who did. The point of interest and importance in these observations is that 39 per cent. of previously non-goitrous children developed thyroid swellings, despite the prophylactic use of iodine for a period as long as one year. It follows, therefore, either that iodine want was not the cause of the thyroid swellings in these children, or that there was a failure of absorption of iodine at the intestinal threshold, or an imperfect utilization of iodine by the thyroid gland or elsewhere in the body.

2. Another potent source of goitre is the confinement of animals in unhygienic surroundings which involve the ingestion with their food and drink of substances derived from their own alvine discharges. There is, indeed, no more potent source of hyperplastic goitre than this. Fish confined in dirty tanks, animals confined in dirty cages, goats tethered on the same plot of ground for many months, and man living on ground contaminated by his own excreta and that of his domestic animals, are all subject to goitre. In all these instances the goitres are more prone to arise if the food be on the borderland of insufficiency so far as iodine is concerned; at least we assume it to be so, since in all, or almost all, the goitre is preventable by the additional provision of iodine. The point of importance is this: that an amount of iodine which may suffice to keep the thyroid gland in health when the animals are living under hygienic conditions of life may not suffice to prevent goitre when they are living under unhygienic conditions of life. In the latter circumstances the iodine ingested is relatively insufficient for the needs of the thyroid gland or of the body generally. Looking at the problem purely from the point of view of iodine want, it would seem that the presence of certain bacterial agents or their products in abnormal situations in the gastro-intestinal tract may interfere with the adequate absorption of iodine. McClendon has found that bacteria are capable of removing iodine from organic media containing it. It may be, therefore, that the continual ingestion of such bacteria, as in polluted water, may cause a part of the iodine in the food to be lost by way of the faeces.

But the problem does not end with iodine intake nor with iodine absorption, for Gaylord has shown, in the case of fish confined in dirty tanks, that the goitre from which they suffer can be prevented as well by the addition of arsenic or of mercury perchloride to the water as by the addition of iodine; while I myself have shown that goitre is preventable in like circumstances by scrupulous cleanliness. It would seem that the biochemical products of certain intestinal bacteria may be absorbed into the system and cause such changes in the biochemistry of the blood and tissue plasma as to make the thyroid glands hypertrophy and hyperplasia imperative; or they may cause atrophic and degenerative changes in the gland. They may, in short, cause impairment of the gland's capacity as a machine or disturbances at the threshold of utilization of its products. Many, indeed, are the possible ways—in the intestine, in the gland itself, and in the tissue plasma—in which intestinal bacteria or their products may cause derangement of the thyroid gland besides their probable interference with iodine absorption and assimilation. But in whatever way they act it is clear that the additional provision of iodine in the food is a potent means of counteracting their action.

3. There is a third means whereby disturbances at the threshold of absorption may cause goitre—namely, by want of balance of the food in certain directions. Thus, the excessive ingestion of proteins, or of certain fats, or of excesses also in man. But here again goitre is much more likely to arise if the animals be of a certain age and if

living under unhygienic conditions, or if the diet be such as favours constipation and intestinal putrefaction. In circumstances of protein or of fat excess in the food thyroid hyperplasia is preventable by the additional provision of iodine. There is, however, one exception to this rule: opossums kept in captivity and fed on a protein-rich diet develop thyroid hyperplasia whether or not additional iodine be supplied with their food (Bensley); so that metabolic differences in different species, and possibly also in different individuals, are not without their influence in determining what effect iodine shall have. It may be mentioned that cod-liver oil will prevent thyroid hyperplasia in animals no matter how unhygienic their conditions of life may be. Cod-liver oil not only provides iodine in suitable form, but vitamins in abundance, while it favours the absorption of calcium and phosphorus, both of which have a part to play in ensuring the normal operation of the thyroid gland.

4. Again, the excessive ingestion of lime for prolonged periods may cause the appearance of "colloid goitres" of small size in some animals. This also is preventable by the additional provision of iodine.

It may therefore be stated as a general rule, to which, however, there are exceptions, that goitres arising in consequence of abnormal conditions at the threshold of absorption are preventable by the additional provision of iodine, provided the iodine be adequately absorbed; but this adequate absorption is dependent on a healthy state of the gastro-intestinal tract; and this, in its turn, on the provision of a well balanced food.

#### *Disturbances at the Threshold of Utilization.*

Turning now to the threshold of utilization: Mention has already been made of the possible influence which the concentration of certain ions in the cell and tissue plasma may have on the action of the thyroid gland's products. There are certain other facts to which reference may now be made. If the thyroid gland be removed in lambs or kids aged 2 to 3 weeks, nothing much happens for eighteen days; thereafter growth ceases (Simpson). And since the phenomena of growth are essentially these of organic synthesis, it may be said that in animals of this age the withdrawal of the thyroid gland's influence impairs organic synthesis and causes the accumulation in the body of the products of an abnormal metabolism. If, however, the animals be 3 or 4 months old growth is but little affected; the withdrawal of the gland's influence is then evidenced chiefly in failure of nutrition of the skin and in loss of intelligence. In these also abnormal metabolites accumulate in the body. The gland's function thus appears to vary with the age of the animal. The effects of thyroidectomy certainly vary with age; with species, with the nature of the food, with the state of nutrition, with external temperature, and other metabolic factors, as Horsley demonstrated in 1885.

Now if instead of removing the whole gland the major part of it be removed in guinea-pigs—an amount sufficient to initiate compensatory hypertrophy in the remainder—then it is found that again nothing much happens for fifteen to eighteen days. Thereafter hypertrophy and hyperplasia occur in the remnant; and this goes on until the deficiency caused by the thyroidectomy is made good, when the regenerated organ settles down to the normal routine of the gland's cycle of activity: storing colloid, resorbing colloid, and secreting moderately and inconspicuously. It is to be noted that the thyroid hyperplasia occurs only after the lapse of a latent period of about eighteen days—that is to say, just at that time when the normal growth and repair of the body tissues are beginning to be imperilled. During this latent period such changes have taken place in the biochemistry of the tissue cells and plasma as to make hypertrophy and hyperplasia of the remnant of thyroid tissue imperative. In this remnant a "goitre" has been produced, inasmuch as it has been called upon to increase its size. The process by which this increase in size has been brought about is, so far as we know, essentially the same as that occurring in the whole gland when parenchymatous goitre is produced. This is an example of how thyroid hypertrophy and hyperplasia may be caused by disturbances at the tissue threshold

—namely, by the presence in the cell and tissue plasma of abnormal metabolites. Similar effects may be produced in the whole gland when similar biochemical changes are brought about at the tissue threshold by other means; as, for instance, by the injection into normal animals of the biochemical products of bacteria, or by the excessive ingestion of these products, or by the absorption of the proteoses produced in the raw surfaces caused by lumps, or by the absorption of other abnormal metabolites, as from toxic foci.

#### INFLUENCE OF IODINE IN PREVENTING THYROID HYPERPLASIA.

As to the effects of iodine in preventing thyroid hyperplasias such as these, it is generally believed that thyroid hyperplasia is due to iodine want. But in the experiment on guinea-pigs above mentioned hyperplasia occurs in the remnant of thyroid tissue although it has at its disposal all the iodine derived from the food, which sufficed to keep the whole gland in health. It cannot be said, therefore, to undergo hyperplasia because of want of iodine. Further, the additional provision of iodine will not prevent the hyperplasia in these animals; indeed, if anything it tends to increase it (Loeb). It may, however, be modified, but not wholly prevented, by the administration of the preformed active principles of the thyroid gland; while Loeb observed the remarkable fact that it is wholly prevented by the administration of the anterior lobe of the pituitary body. We see, therefore, that the metabolic need which determines the compensatory hypertrophy and hyperplasia is in this case so imperative that no amount of iodine can prevent the thyroid enlargement, and that it is one which concerns other endocrine structures as well as the thyroid gland. Similarly, in dogs iodine will prevent compensatory hypertrophy in the remainder of the gland provided not more than five-sixths of it be removed. But if less than one-sixth to one-ninth be left behind no amount of iodine will prevent compensatory hypertrophy in the fragment that remains (Marino). It would seem, then, that thyroid hyperplasias which result from disturbances at the tissue threshold are not always amenable to control by iodine. In this respect they are in marked contrast to those resulting from disturbances at the threshold of absorption. They are not due to iodine want, nor to a drop in the gland's store of iodine below a certain level; but this drop occurs as a result of the hyperplasia, and the hyperplasia itself is the result of biochemical changes in the cell and tissue plasma.

Etologically speaking, we have, then, to deal with two types of thyroid hyperplasia: the one, resulting from disturbances at the threshold of absorption, which is usually preventable by the additional provision of iodine in the food; the other, resulting from disturbances at the threshold of utilization, which is usually not preventable by the additional provision of iodine in the food.

So much, then, for what iodine will and will not do in preventing thyroid hyperplasias. I have presented both sides of the picture, since if iodine be used indiscriminately the same fate may overtake it as befell it more than fifty years ago; it may fall into undeserved disrepute unless its limitations be realized. So far as my own investigations permit me to form an opinion, I have come to regard iodine as a substance which initiates and maintains the normal cycle of the thyroid gland's activities—it is, so to say, the oil of the thyroid engine—but I do not regard the efficient working of the thyroid mechanism as a matter solely of lubrication, important though this be.

#### TYPES OF SIMPLE OR NON-TOXIC GOITRE.

I have observed three types of goitre to arise under experimental conditions in animals: the first, in which there is a balanced exaggeration of all the normal features of the gland's cycle of functional activity—that is, of both active secretion and colloid storage; the second, in which active secretion occurs to the almost complete exclusion of colloid storage; the third, in which colloid storage occurs to the almost complete exclusion of active secretion. The first may be described as hypertrophic goitre; the second as

hyperplastic, parenchymatous, or adeno-parenchymatous goitre; the third as diffuse colloid goitre. In animals under experimental conditions the first or purely hypertrophic type is an early stage of the second or adeno-parenchymatous type. It has been observed to arise particularly in young animals kept under insanitary conditions of life or fed on faecal material or on cultures of faecal bacteria. The second arises under similar conditions; its histological features being well marked in older animals and in congenital goitres experimentally produced by feeding the parent throughout pregnancy on cultures of faecal bacteria. It arises also in adult animals, especially if they be kept under insanitary conditions of life, whose food contains an excess of proteins or of certain fats or of both. The third arises in animals whose food contains an excess of lime. These three types of goitre have their counterpart in man:

(1) *Hypertrophic goitre* may be a purely physiological condition occurring in childhood, at puberty, during pregnancy or the menopause, and in the course of ovarian disorder; or it may be pathological, as when it represents the beginnings of adeno-parenchymatous goitre.

(2) *Adeno-parenchymatous goitre* is the true endemic goitre of such mountainous regions as the Alps and Himalayas; it may also occur sporadically.

(3) *Diffuse colloid goitre* may occur sporadically or endemically, the latter usually in lowland areas.

#### Adeno-parenchymatous Goitre.

The characteristics of this type of goitre are these: it has its favourite endemic haunts in the great mountain ranges of the world; it is associated with certain forms of cretinic degeneration—congenital goitre, cretinism, deaf-mutism, and idiocy; in the regions where it prevails as an endemic it is rarely or never associated with exophthalmic goitre; the incidence of the acquired disease is low in childhood, but increases gradually with advancing years (Fig. 1); it is

FIG. 1.—Age incidence of adeno-parenchymatous goitre in females: Gilgit, Himalaya.

essentially a hyperplastic goitre; it is of the diffuse, parenchymatous, but often unsymmetrical, type in young subjects; of the adeno-parenchymatous type in older subjects (in the latter the enlarged organ almost invariably contains one or more adenomata); it usually leads to some degree of hypothyroidism in the adult—the cretinic degenerations with which it is associated are the outcome of this thyroid deficiency in the mother; it may be associated, as in Himalayan India, with symptoms referable to other endocrine glands, particularly the parathyroids (endemic tetany and tetanic cretinism are examples); the greater the degree of endemicity the more does the sex incidence approach the ratio 1 to 1, the lesser the degree of endemicity the more does the incidence of the disease in females exceed that in males; newcomers to an endemic area may acquire the disease in as short a period as fifteen days to six weeks, although the "incubation period" is usually longer.

These are the criteria on which the endemicity of this form of goitre is to be based. In Himalayan India, and in other localities where I have had an opportunity to study this malady, it is associated in its origin with insanitary conditions of life, particularly with contaminated water supplies; and is the same disease which occurs under experimental, and like, conditions in animals. It may be that the bacterial agents which are the cause of the disease are favoured in their operation by a deficient intake of iodine in the food and water. This I do not know from actual analysis of the food and water in those regions where I have observed the disease; but judged from the effect of an additional supply of iodine in preventing the hyperplastic goitres which arise in animals under like conditions of insanitation, it seems almost certain that the iodine intake with the food is deficient relatively to the unhygienic conditions of life under which the malady develops in man. It is curable in its early stages by the oral administration of such drugs as thymol. It is preventable by the provision of pure and protected water supplies without increasing the iodine intake with the food. It is to be remembered that the administration of iodine to adults who are the subjects of adeno-parenchymatous goitre is likely to cause hyperthyroidism; this harmful effect of iodine appears, however, to vary in different localities.

#### Diffuse Colloid Goitre.

This malady may occur sporadically or endemically. It differs in its distribution from the "endemic goitre" of mountainous regions. In this connexion the following passage from De Quervain's writings may be quoted:

"The histological structure of goitre varies according to locality. In certain countries, especially in level regions, the diffuse colloid goitre, with or without hyperthyroidism, and exophthalmic goitre predominate. In more mountainous countries the toxic goitre is the exception, and the nearer one approaches the centre of the endemic area (as in the Alps and Himalayas) the less one meets with colloid goitre. It is replaced by the colloid-poor, diffuse parenchymatous goitre in childhood and by the adeno-parenchymatous nodular goitre with its degenerative forms in adults."

In general, then, colloid goitre would seem to be most often found in lowland localities. It appears to be the common variety of goitre in America, and possibly also in the British Isles, but in the latter no attempt has been made, so far as I am aware, to separate it from the adeno-parenchymatous type, or to determine the distribution of either. It is commonly associated in the same locality with exophthalmic goitre. It does not appear to be associated with, or to be a cause of, cretinic degenerations; at all events true endemic cretinism is said to be unknown in America (Gordon). The nearest approach to the experimental production of a similar condition in animals has been arrived at by feeding them on food containing an excess of lime. In these circumstances colloid storage occurs to the almost complete exclusion of active secretion: but the enlargements so produced were small, and the amount of lime used to produce them was large. I am not prepared to state that colloid goitre in man is due to such excess of lime in the food or to do more than say that my experimental production of colloid goitre in animals by this means affords some indication of the factors which may be concerned in its causation in man. Colloid goitre in animals is preventable by the additional provision of iodine in the food; it appears also to be preventable by this means in man.

Both adeno-parenchymatous and colloid goitre may occur in the same locality. The only attempt to separate them with which I am familiar is that of Levin in a certain region of the Great Lakes of North America, where he found 1,146 cases of goitre in a community of 1,783 persons. His work has brought to light several very interesting facts in regard to the course and behaviour of these two types of goitre. In one of his charts (reproduced in Fig. 2) he separated the adeno-parenchymatous goitres from the diffuse, non-adenomatous goitres. The latter include the diffuse hypertrophies of childhood and

diffuse colloid goitres. It will be observed that the age incidence curve of the adeno-parenchymatous goitre is practically identical with the age incidence curve of the disease as it occurs endemically in Himalayan India (Figs. 1 and 2); in both localities the malady is due to causes the effects of which become more and more manifest as age advances. The other group, which includes the thyroid swellings of childhood and the diffuse colloid goitres, is seen to have its highest incidence in early life, tending to disappear after full maturity has been attained. This tendency is more marked, and sets in earlier, in males than in females. Colloid goitre is thus in marked contrast to adeno-parenchymatous goitre: it would appear to be due to causes whose effects become less and less evident as age advances; adeno-parenchymatous goitre to causes whose effects become more and more evident as age advances. If the former be due solely to iodine want then it would seem that the effects of this want become less conspicuous after full maturity has been attained. If the latter be due solely to iodine want then it would seem that the effects of this want become more conspicuous after full maturity has been attained. There must, therefore, be more in the problem of the causation of these two types of goitre than iodine want.

FIG. 2.—Age incidence of (broken line) adeno-parenchymatous goitre, and (continuous line) diffuse colloid goitre, including childhood goitres, in females: Great Lake Area, U.S.A. (After Levin.)

Again, if this be the cause of both types, then we have the remarkable fact of iodine deficiency producing two diametrically opposite effects in the thyroid gland: (a) hyperplasia to the almost complete exclusion of colloid storage, and (b) colloid storage to the almost complete exclusion, or greatly in excess, of hyperplasia. Yet, paradoxical as it may seem, this can actually occur. Thus, if in adult animals the iodine deficiency be relative to an excess of fats in the food, or to certain conditions of bacterial infection of the intestinal tract, goitres may result in which hyperplasia occurs to the exclusion of colloid storage. If, however, the iodine deficiency be relative to an excess of lime in the food, then colloid storage may occur to the exclusion of hyperplasia. In both cases the administration of iodine restores the normal cycle of the thyroid gland's activities, and for practical purposes both may be said to be due to relative deficiency of iodine. But it is the factors which give rise to the relative deficiency of iodine, rather than the iodine deficiency itself, that are of importance in determining the histological character of the goitre; and, as would seem from the course in man of the two types of goitre with which we are dealing, it is these factors also which determine the persistence of the goitre in the individual. Important, then, as iodine is in preventing either type of goitre, it is to be remembered that, in the causation of both, other factors are concerned which impart to each its own particular characters.

*Childhood Goitre.*

It was my intention, had time permitted, to refer in some detail to childhood goitre, since many of the observations hitherto recorded in regard to goitre prevention by iodine relate to the thyroid swellings of childhood. I must, however, content myself with the mention of a few points. Many of these swellings in children are physiological hypertrophies often normal to the individual, and have no title to be classed as "goitre"—a term which signifies thyroid disease. The great majority of them—as many as 98 per cent. (Olin)—are slight, some so slight that but a fleeting glimpse of the gland's outlines are caught as the child swallows. If all these be classed as goitre a wholly erroneous idea of the prevalence of thyroid disease may be gained. Further, estimates as to the prevalence of goitre may vary within wide limits according to what the observer may regard as a goitre. Thus, in a school where goitre was endemic, I have known the malady suddenly to assume epidemic proportions with the advent of one school medical officer, and the epidemic to disappear as suddenly with the advent of another.

A small minority of thyroid swellings in children are true goitres; in Himalayan India these goitres are conspicuous, often unilateral and right-sided, but sometimes regular and bilateral enlargements of the gland, which not infrequently are associated with engorgement of the veins of the neck; they may persist through puberty into adult life and begin to show adenomatous nodules in their substance as early as the twelfth year. They are as obviously true "goitres" as similar swellings in older subjects. "Childhood goitres" attain to their highest incidence in boys at the age of 9 and in girls at the age of 10 in Himalayan India; but the peaks of highest incidence appear to differ in different localities and appear also to be related to the prevailing type of goitre. Thus, where colloid goitre is the prevalent type, childhood goitre is said to be at its highest incidence in boys about the age of 8 to 10, and in girls about the age of 12. The incidence of thyroid enlargement in children below the age of puberty is not of itself a true index of the endemicity of goitre; its incidence may be low and yet the endemicity of adeno-parenchymatous goitre be high, or the incidence of childhood goitre may be high and yet goitre may not be a conspicuous feature in the adult population.

The incidence of childhood goitre is only of value as evidence of prevailing thyroid disease when considered in relation to the other criteria of endemicity and to the prevalence of goitre in the adult population. A marked characteristic of the thyroid swellings of childhood is their tendency to spontaneous disappearance. This tendency varies in different localities, and is probably related to the prevailing type of goitre; in endemic foci in Himalayan India I have found 11 per cent. of these swellings to disappear spontaneously in boys and 9 per cent. in girls; Nicholson has placed the figure as high as 50 per cent. in a certain endemic area in the Himalayan foot-hills; while Bircher reports that although 70 to 100 per cent. of children may be the subjects of swollen thyroids in certain parts of Switzerland, not more than 3 to 9 per cent. of young men are rejected because of goitre when they present themselves for military service. It is necessary to bear these facts in mind, not only when inaugurating iodine prophylaxis in any locality, but when attempting to form an estimate of its value.

**CONCLUSION.**

I have endeavoured to indicate the broad lines on which we must, in my opinion, view diseases of the thyroid gland. It is, I believe, rare that any metabolic disorder such as goitre is due to a single cause. There is, as a rule, a multiplicity of factors involved. The thyroid gland cannot be considered apart from the rest of the body, nor iodine apart from other food constituents. The time has come when we must search more closely for causes of the thyroid gland's disorders in disturbances at the threshold of absorption in the intestine, in disturbances at the threshold of utilization in the tissues, and in disturbances in the cell and tissue plasma of the gland itself.

**An Address**

ON

**DUODENAL AND GASTRIC  
ULCERATION:****SOME PERSONAL EXPERIENCES.\***

BY

**T. P. DUNHILL, C.M.G., M.D.,**ASSISTANT DIRECTOR, SURGICAL PROFESSORIAL UNIT,  
ST. BARTHOLOMEW'S HOSPITAL.*(With Special Plate.)*

I HAVE chosen this subject for two reasons. In the first place, whether we be general practitioners, physicians, or surgeons, its problems are constantly coming before us, and have to be dealt with. No one can believe that the methods of treatment are so standardized that the right and only thing to be done in each instance is settled, and we have all lived long enough to know that what we have done has not invariably turned out to be the best. Men of large experience have written and spoken extensively on this subject, and I make no pretence of saying the final word on this occasion; but we each in our different capacities have to accept responsibility towards those patients who come to us for advice. In the second place, I have for some years tried, in conjunction with my colleagues, to attain the maximum degree of accuracy in diagnosis of gastric and duodenal ulcers by means of x-ray examination. The skiagrams are typical of the results that are to be expected whenever a patient is well enough to have the examination made.

I shall not attempt to cover all the ground. This short address must perforce be discursive. In any surgeon's experience sometimes questions of diagnosis appear to him to be of rather more than ordinary interest; the result of x-ray examination often surprises him; and always he has to adapt his surgical procedures to the material which confronts him. It is around these aspects of the question that I propose to speak.

Before saying anything more I want to acknowledge my personal debt to Sir Berkeley Moynihan (whose work has always been open to visiting surgeons, and whose friendly help has been given to many of us), to Mr. Sherren, and to Mr. William Mayo. To some extent we evolve our individual methods in the course of dealing with our own patients, but certain trails have already been blazed for us, which lessen our anxieties and save our patients from some dangers. To these pioneers our debt is deep.

In dealing with gastric and duodenal ulcers, as with osteo-arthritis, exophthalmic goitre, tuberculosis, and many other diseases, the aim of our profession is to prevent their occurrence, and one by one we may hope to see them disappear; but in the meantime we find our patients seriously ill, being already in a condition which hampers their activities, gives them pain, and puts their lives in danger. Usually they have not consulted a surgeon until their disease has become well established, but many of them have come to you earlier, and some of them reach the surgeon without having had sufficient guidance. Therefore etiology should always be present in our minds. The hygiene of the month, arrangement of diet, treatment with drugs, limitation of smoking, and proper rest, may cure in the early stages, and will relieve in all. No surgical operation should be undertaken until all these points have been attended to; for by these means operation may sometimes be rendered unnecessary, and operation will fail to achieve its object if the cause of the condition is not removed.

At what stage, then, are we to say, "This patient should be subjected to operation?" For myself, that time is when the patient, in spite of efficient medical treatment, suffers

\* Given at Felixstowe to the Suffolk Branch of the British Medical Association, October 31st, 1924.

so much pain or inconvenience that work cannot be carried on, sleep is interfered with, and life becomes a burden. The symptoms may never have responded to treatment, or may have recurred from time to time in spite of it; or certain complications may occur which force our hands.

The cases which I propose to discuss are all such as have reached the stage at which, in the judgement of physician and surgeon, the time has come for surgical help in treatment. I put it in that way because it is only "surgical help" in treatment. These patients are not all cured by operation in the way a person is cured who has had an appendix removed during an attack of appendicitis, or cholecystectomy performed for a stone impacted in the cystic duct. A great many are cured; others are so greatly improved that, with ordinary care and some guidance, pleasure in life is regained and work can be carried on with zest. A few have had so large a part of their stomachs destroyed by a long-standing callous ulcer that, whatever method of operation may have been adopted, they are still not normal beings afterwards; they will have been relieved of their intense pain, but will always require guidance in feeding. Then, again, occasionally a gastro-jejunal ulcer will follow a gastro-jejunostomy. It is therefore obvious that there should always be the closest co-operation between physician and surgeon if the patient is to derive the benefit he has the right to expect from our profession.

In an uncomplicated case of duodenal ulcer the symptoms are characteristic. Even in the clearest cases it is satisfactory to have a skiagram which demonstrates the lesion. Fig. 1 is from a patient (of Dr. Morison) whose symptoms might have been taken from a textbook, so accurately did they fit in with the recognized picture. He had pain two hours after a meal, more food always "sending it away." He regularly had an attack of acute pain at 3 or 4 o'clock in the morning, which he would relieve by taking an alkaline mixture; he would then go to sleep again. He had the usual periods of complete freedom from pain. The skiagram shows the distortion of the duodenum, with the barium mixture trickling past the obstruction in a thin stream, and filling the duodenum farther on. But I find that many of the patients, by the time they reach the surgical ward of a hospital, do not give this clearly cut history. In some it can be elicited by careful investigation; in others I fail to obtain it.

Pain such as we expect has been absent in one group of cases. In illustration of this group I show skiagrams of a man and woman, both of whom discovered blood in their stools. From the man I could only get the slightest history of indigestion, and he had not troubled to modify his food as so many patients do; but the melaena had occurred frequently enough to alarm him. The woman stated that she had "queer feelings" two hours after a meal, but her own description of it was that "it was like someone pushing a fist into her back." I could not get an admission from her that she suffered any pain, or that there was abdominal discomfort. Her haemorrhages had been severe. The man was aged 46 and the woman 58. The most common cause of severe melaena is duodenal ulcer; but from the history I could not otherwise satisfy myself of the presence of duodenal ulcer. A skiagram of the man (Fig. 2) gives a cruciform picture from the distortion of the first part of the duodenum. Fig. 3 is a skiagram of the woman, showing the crater of an ulcer filled with barium. In cases of this kind a good skiagram gives conclusive evidence, such as can be obtained in no other way, and it shows the extensive duodenal ulceration that may occur without pain.

As opposed to the cases with unusual freedom from pain, there are others in which pain is atypical in time or intensity, either because of the complications of the lesion itself or of associated conditions. A man was known to drink more wine than he should, and to do so throughout the day. For the last two or three years he had taken considerably too much. During the last eighteen months he had had severe bouts of pain in the upper abdomen with vomiting. It began each time with a feeling that he was not fit, and that an attack was imminent. After a day or two this deepened into pain right across the upper abdomen, which steadily increased in severity and never

stopped except when he vomited, which he did several times a day. Vomiting gave relief for an hour or two, the pain then gradually returning. The intense stage of the attack lasted about three days, and then the pain and vomiting subsided. He was closely questioned as to any relationship between the pain and food, but none could be detected. I believed his attacks to be due to alcoholic gastritis, but I suspected that he might have gall stones, for when the pain was present it was continuous, and when the attack passed his digestion was good. Exploratory operation was performed rather under protest, and a very large duodenal ulcer was found, the inflammatory mass being firmly adherent to the head of the pancreas and the neck of the gall bladder. The liver was cirrhotic. These symptoms were quite unlike those usually present with duodenal ulcer. The patient had been examined by the x rays before I saw him. I believe a skiagram by an efficient radiographer would have definitely demonstrated the lesion.

An ulcer on the free surface of the duodenum may perforate, but this we are not considering to-day. Apart from perforation its base may become adherent to neighbouring structures and surrounded with an inflammatory mass; Fig. 4 illustrates such a case. A narrow channel filled with barium mixture is seen over a considerable length in the pyloric region; the stomach is filled proximally to it, and the duodenum ballooned distally to it, implying the presence of the rigid inflammatory mass which surrounded the duodenal region and showing the barium filling the deep narrow penetrating ulcer. (This skiagram will be referred to more than once later. It presents points of resemblance to gastric carcinoma, also it shows two calcified tuberculous glands above the lesser curvature.) The ulcer, if not on the free surface, may penetrate deeply posteriorly, producing a large inflammatory mass, which may involve, and not infrequently penetrate, the head of the pancreas. Either of these conditions may induce pain which is intense and almost constant, quite unlike the typical pain of duodenal ulcer.

When these conditions have caused narrowing of the lumen of the duodenum, the signs and symptoms of retention of gastric contents are added to those of ulcer. Furthermore, there are sometimes other signs associated with these last mentioned conditions which may be perplexing. I call to mind five men, each of whom had a palpable tumour, seeming to be a little larger than a golf-ball, movable within limits. A distinguished American surgeon has made the pronouncement that when a tumour of the stomach is big enough to be felt it is too late for surgical cure. All of these men had apparently reached that stage. In each the condition was associated with pain which had become very constant. Whether a lump is due to a neoplasm or an inflammatory mass some stenosis is always present, and in each of these there was evidence of gastric retention. One man had vomited constantly for ten days. Another carried a stomach tube in his pocket, and drew off the stomach contents as soon as the pain became intolerable. A third had vomited so constantly for so long a time that his medical attendants regarded surgical intervention as being quite impossible. In these three patients emaciation was extreme; in the other two vomiting and wasting, though present, were not so marked. Fig. 5 shows a pool of barium mixture lying at the bottom of an enormously distended inert stomach; the barium-filled crater of the duodenal ulcer is seen above and to the left.

It is extremely difficult in the presence of a palpable tumour to come to an exact diagnosis between carcinoma at the pyloric end of the stomach and duodenal ulcer penetrating deeply and surrounded by a mass of inflammatory tissue. The inflammatory condition does not necessarily fix the tumour. The history may be long or short. A long history suggests the possibility of a gastric ulcer which has become malignant, a short one that the lesion is unlikely to be an ulcer and has been a carcinoma from the first.

Does x-ray examination help us in these cases? Some patients are far too ill for investigation to be made at the time when the surgeon first sees them. Two of these five

FIG. 1.—Stenosis in first part of duodenum. (Skiagram by Dr. Vilvandre.)

FIG. 2.—Duodenal ulcer: a not infrequent type of distortion with ballooning beyond. (St. Bartholomew's Hospital skiagram.)

FIG. 3.—Duodenal ulcer. Crater filled with barium mixture. (St. Bartholomew's Hospital skiagram.)

FIG. 4.—Duodenal ulcer; stenosis. Crater filled with barium emulsion. Ballooning of duodenum beyond stricture; indentation of pyloric end of greater curvature simulating filling defect of cancer. Two calcified tuberculous glands at cardiac end of lesser curvature. (Skiagram by Dr. Vilvandre.)

FIG. 5.—Large circular ulcer of duodenum filled with barium mixture. Pool of barium mixture lying in a big atonic stomach. (St. Bartholomew's Hospital skiagram.)

FIG. 6.—Carcinoma of pyloric segment of stomach, showing filling defect. (Skiagram by Dr. Vilvandre.)

FIG. 7.—Marked stenosis of commencement of the duodenum due to ulcer, associated with great dilatation of the stomach and emaciation; death from bronchopneumonia following operation. (Photograph by Miss Vaughan.)

FIG. 8.—Hour-glass stomach with saddle-shaped gastric ulcer: upper part invading left lobe of liver; lower part invading pancreas. Sleeve resection. Patient perfectly well. (St. Bartholomew's Hospital skiagram.)

FIG. 9.—Very narrow hour-glass constriction. Sleeve resection. See Fig. 10. (St. Bartholomew's Hospital skiagram.)

FIG. 10.—(a) The same patient as Fig. 9 one month after operation, showing filling defect caused by the inrolling of the approximated edges of the stomach by the Lembert sutures. (b) Twelve months later; the filling defect has disappeared, the shape and motility of the stomach are practically normal.

FIG. 11.—(a) Hour-glass constriction of stomach. (b) The stomach after the Polya-Balfour type of operation. (St. Bartholomew's Hospital skiagrams.)

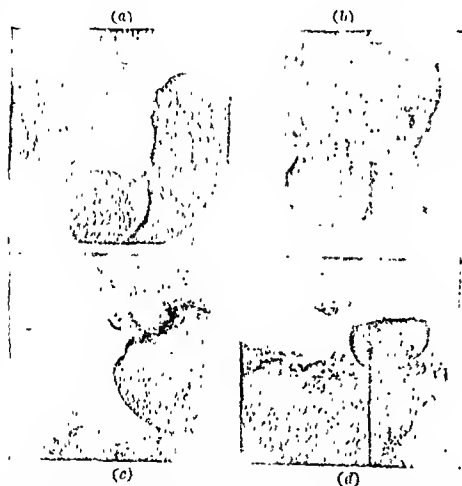

FIG. 12.—(a) Immediately after a meal. The gastric ulcer is shown at the middle of the lesser curvature. Notice also the barium entering the cardia. (b) Two hours later; the gastric and duodenal ulcers are both shown. (c) The same patient after six hours. Both ulcers are shown. (d) At eight hours after the meal. The duodenal ulcer crater is filled and there is considerable residue remaining in the stomach. The gastric ulcer was proved on microscopical examination to have become malignant. (Skiagrams by Dr. Salmond.)

FIG. 13.—(a) Deep incisura extending from lesser curvature, showing narrowing of stomach at the site of a healed ulcer which had been active thirty years previously. (b) Skiagram taken three months after (a). The gall bladder contained calculi. (Skiagrams by Dr. Salmond.)

FIG. 14.—An ulcer below and behind the lesser curvature. With a thick meal it is only seen on rotating the patient almost transversely. (St. Bartholomew's Hospital skiagram.)

FIG. 15.—? Ulcerated diverticulum at cardiac orifice of stomach in a tuberculous patient. Inset: Diverticulum still filled with barium mixture after stomach is practically empty. (New Lodge Clinic skiagrams.)

had been steadily getting worse until the operation had to be performed as an emergency measure. If the patient is not too ill, x-ray examination may settle the diagnosis. Fig. 5 is obviously the picture of a large duodenal ulcer with such degree of associated stenosis that the peristaltic vigour of the stomach had diminished and atony resulted. But if Fig. 4 be compared with Fig. 6 it will be seen that the problem is more difficult. The history was identical in each of these two cases, and the age practically the same—about 60 years. In each a tumour could be felt of the same size. Each moved with respiration and was mobile apart from respiration. In each the skiagram appeared to show a filling defect at the pyloric end of the stomach; the indentation of the wall in this area and the narrowing of the pyloric region over a considerable length may be noted. From the skiagram I believed the condition in Fig. 4 to be carcinoma, and I was sure that Fig. 6 indicated the same. Both patients were too ill for a complete operation to be performed at one time. In each gastro-jejunostomy was performed in order to tide the patient over the emergency. In each the tumour was seen and palpated, and in each it appeared to be carcinoma. In one a carcinoma was removed a fortnight later. In the other the second operation was delayed on account of lung complications, and when the abdomen was afterwards opened for the partial gastrectomy all signs of the tumour had disappeared, the pylorus and duodenum being then soft and unscarred. (The deeply penetrating ulcer shown in Fig. 4 had been on the posterior surface.)

It is easy to be wise after the event. In a review of these cases it should be realized that in Fig. 4 the barium entered a long narrow ulcer cavity, quite unlike the cavity of a carcinomatous ulcer; the inflammatory mass surrounding this had thickened, hardened, and indented the stomach wall in its vicinity, and given a skiagram bearing a considerable resemblance to that produced by the carcinoma in Fig. 6.

An associated pathological condition will alter the characteristic history of duodenal ulcer. We have all seen a gastric and duodenal ulcer in the same patient. Moynihan states that a duodenal ulcer is present in 12.3 per cent. of all cases of gastric ulcer. Tuberculous glands are also not infrequently found. Fig. 4 shows, in addition to the duodenal ulcer, two calcified glands along the line of the lesser curvature of the stomach. These may not only make the history less clear, but make the prognosis less perfect. Needless to say, when an abdomen is opened the search for other pathological conditions should be very thorough, even though the ulcer is obvious; for if tuberculous glands are present—as they have been in several of my cases—and are not discovered, the surgical treatment may be deemed to have failed, while actually the remaining symptoms are due to other causes.

In at least two conditions special care is required in planning surgical interference. These are: (1) extreme emaciation from increasing pyloric stenosis with consequent starvation, and (2) repeated haemorrhages. On four occasions I have been able to perform a gastro-jejunostomy very easily and quite successfully with local anaesthesia, when the patient appeared to be too emaciated and weak to justify the use of general anaesthesia; on one occasion I lost, through lung complications, a patient who I believe would have been saved if I had used local anaesthesia. He was the patient who had either vomited or emptied his stomach with a tube every day for many months in order to relieve his pain, and he was emaciated to a skeleton. Fig. 7 is a photograph of the organs removed at autopsy. The first part of the duodenum is seen to be narrowed. It is very thick-walled and the lumen is almost obliterated. Sometimes a patient recovers from repeated haemorrhages sufficiently to undergo operations safely, but occasionally it seems impossible to control the haemorrhage from the ulcer, and day by day the patient becomes weaker and paler. These patients have several times been rendered fit for the appropriate surgical measures by means of blood transfusion.

In gastric as in duodenal ulcer there are long periods of latency, which lead patient and practitioner to believe that the pathological condition has disappeared. There may be

some cases in which the ulcer has healed, but there are many in which it has not. Again, as in duodenal ulcer, the history of gastric ulcer in its early stages is much more characteristic than in the later stages. In many cases which come to the surgical wards of a general hospital the characteristic history has long passed, and the story may have to be reconstructed from the patient's memories of long ago. One man recently came to us who twenty years before had had the orthodox symptoms—pain an hour and a half after food, lasting half an hour, disappearing before the next meal. He had continued in this state for fifteen years, being sometimes better, sometimes worse. Then a severe haemorrhage rendered his admission to hospital necessary. He was discharged "cured." Still later—twenty years after the onset of the first symptoms—there was another attack of haemorrhage, and from this time onwards he was scarcely ever free from pain, day or night. The pain, the sleeplessness which the pain induced, the inability to take food, the loss of blood (which could always be detected in his stools), and the resulting exhaustion made him pallid, emaciated, and very ill. During all this time the ulceration had been slowly progressing; the base of the ulcer became adherent to and eroded the body of the pancreas, while surrounding inflammation in the wall of the stomach resulted in the formation of an hour-glass stomach.

When once these ulcers have penetrated the gastric wall so that the base is formed by structures outside the stomach, the reaction surrounding them may be intense, and the inflammatory products constitute a mass which may fill the upper left quadrant of the abdomen, and extend below the umbilicus. This area will be rigid and without movement on respiration. The rigidity and the tenderness may prevent any effective examination of the abdomen. In one patient of this type pain occurred within a few minutes of taking food and lasted about two hours. He would vomit at any time during this period, but obtained only slight relief. The pain was violent; it "doubled him up," and prevented him from sleeping; he was afraid to take any food except egg and milk. He obtained a little relief by lying in the left latero-prone position. Four weeks before admission to hospital he had vomited blood. He was far too ill for an x-ray examination to be made. He presented the picture of late malignant disease of the stomach, but because of his age (34) his abdomen was explored. There were enlarged glands in the great and lesser omenta. A large hard mass involved the lesser curvature and posterior wall of the stomach and extended up to the cardia; it appeared to be infiltrating the left lobe of the liver. A partial décollement was made in order to examine the stomach from below; it was found to be firmly fixed to the pancreas. The condition was regarded as malignant and inoperable. Three glands were removed for examination and the abdomen closed. The glands were found to be non-malignant, and the patient improved sufficiently to enable an x-ray examination to be made. The result is shown in Fig. 8. The barium mixture is seen filling a large ulcer crater above the lesser curvature; the base of this was formed by the liver, and opposite this, bulging below and overlapped by the greater curvature, is seen the edge of a very large barium-filled crater which had burrowed into the pancreas. The middle third of the stomach immediately below these ulcers was almost obliterated. When the stomach was dissected off the liver and pancreas scarcely any middle third remained. The free edges of the proximal third were very ragged and the induration along the lesser curvature and posterior wall extended almost to the cardiac orifice. The patient suffered from marked aortic disease, and as the distal third of the stomach was healthy it seemed wise to save time by trimming off the ragged indurated edges and joining up the two ends of the stomach. This patient is quite well two and a half years after the operation.

Even when patients are not so ill as in the last case the diagnosis is not always easy. In women it has not infrequently happened that the pains have been so much worse about the menstrual periods, and have appeared not to be so definitely related to food, that attention has been directed to other organs of the body. Of two women who came for treatment, one had had four, and the other three,

previous operations on the lower abdomen and pelvic organs; all these operations were for pain, which was ultimately proved to have been due to gastric ulcer. In one of them the skiagram shows an extremely narrow hour-glass constriction; this case is interesting in that the ulcer perforated immediately above the site of constriction. The hole was big enough to admit a finger, and the stomach contents were mixed up around and between the adhesions consequent on three previous abdominal operations (one of which unfortunately had been a double oöphorectomy). The perforation was closed, and, as soon as the patient was fit for it, an x-ray examination was made. The result is shown in Fig. 9. It was realized that this patient would be in a precarious state if the stomach were left in this condition. It was known that the abdomen was matted with adhesions rendering it difficult to apply the jejunum to the proximal end of the stomach, so it was decided to perform a sleeve resection. The resulting shape of the stomach soon after operation is shown in Fig. 10a. At this early stage the filling defect in the stomach outline caused by the inrolling of the approximated edges of the stomach wall by Lambert sutures is seen. The stomach functions well, and the patient has since married. A recent photograph has been obtained showing the stomach shape and motility to be practically normal (Fig. 10b).

It is not often possible to apply stomach clamps in the manner figured in textbook illustrations of sleeve resection. The cases in which clamps can be applied rarely require sleeve resection, and in those which demand it the surgeon must use all the skill of which he is possessed to cobble together the distal third on to the ragged remains of the proximal piece, so that the posterior wall may be safe and efficient. In the patients upon whom it has been found necessary to perform sleeve resection on account of the exigencies of the condition the late progress has been quite good. Fig. 10b shows a stomach in which abnormality can scarcely be detected.

Usually in cases of hour-glass stomach due to ulcer in the middle third, when the case has been carefully worked out, and the x-ray examination—fixing the site of the ulcer and the degree of mobility of the stomach—has enabled the operation to be properly planned before the abdomen is opened, a partial gastrectomy is performed, the proximal end of the duodenum is closed, and the jejunum anastomosed with the open end of the remaining piece of stomach—Balfour's modification of the operation originally planned by Polya. Figs. 11a and 11b show the hour-glass constriction, and the condition of the viscera subsequent to operation. This operation has proved to be most satisfactory in the cases which have been severe enough to necessitate it. I believe the patients are more free from subsequent discomforts than after any other operation for gastric ulcer in this situation. The only disadvantage I have found is that in a few cases the size of the meal has to be restricted. If this is regarded the patients are happy, and as this operation has usually been performed for very disabling pain they do not mind the slight restrictions. Some are so hungry afterwards that, as one man put it, "I really cannot keep myself away from food."

I have already mentioned the simultaneous occurrence of gastric and duodenal ulcer. Figs. 12a, b, c, d, show the appearance on x-ray examination of such a dual condition: 12a is immediately after the meal; 12b in two hours; 12c shows the condition almost unchanged in six hours; and at eight hours (12d) there is still a barium residue in the crater of the duodenal ulcer. At operation the gastric ulcer was found to be about one and a half inches in diameter and an inch in depth. Examination of the specimen showed that it had penetrated into the body of the pancreas. The duodenal ulcer was on the posterior inferior aspect of the first part of the duodenum; that also is a considerable ulcer. A finger could invaginate the anterior wall of the viscus into the crater of each ulcer easily. The skiagram 12a shows barium in the oesophagus and entering the stomach, so that the position of the cardia is defined. It also shows that there is probably sufficient of the proximal part of the stomach still unaffected to permit a partial gastrectomy. The Polya type of operation, planned to include both ulcers, appeared to be the most suitable pro-

cedure for the condition, and it was performed. The concave floor of the gastric ulcer consisted of pancreas. It was wiped clean, and a layer of great omentum tacked over it with a catgut stitch after the stomach had been dissected free from it. When this man was seen by his latest consulting physician before operation he stated that he had no pain in his abdomen, but an intense pain deep in the middle of the right side of his chest and in his right shoulder-blade, and that it had no relation to food. It had become constant and unbearable. Microscopical examination of the gastric ulcer showed that it had become malignant, thus bearing out the statement that gastric ulcers more than one inch in diameter are prone to be malignant.

Figs. 13a and 13b are shown to illustrate the permanent change which may occur in the shape of a stomach with the healing of a chronic ulcer. These two skiagrams were taken with an interval of three months between them. A similar picture is given on each occasion—a deep narrow incisure cutting into the stomach from the lesser curvature. This was unaffected by peristaltic waves. On other films of this patient the outline of the gall bladder can be easily seen. Thirty years previously he had suffered from a gastric ulcer. He had been seriously ill for six months and an invalid for two years. After four years he could take ordinary food, but often suffered from indigestion. Twelve months before these skiagrams were taken discomfort after food became more insistent, but the symptoms were rather suggestive of gall stones. At operation the gall bladder was found to contain many gall stones. After dealing with this, and removing a firmly bound down appendix, the stomach was opened in its long axis across the constriction for two and a half inches. This was to determine if there was any active ulceration present, and to restore a normal shape by suturing the incision transversely to the long axis of the stomach. The ulcer had healed, the stomach wall was soft, but the stenosis was such that it would just about admit a thumb.

Fig. 14 is the skiagram of an ulcer which, in the days when a large barium meal was given, instead of the small fluid meal, might only be discovered by a lateral view of the patient. The position of the vertebrae shows how much this patient was rotated before the ulcer became visible.

Two conditions are met with which present great difficulty: one is persistent uncontrollable haemorrhage from an ulcer; the other is gastro-jejunal ulcer. The records of St. Bartholomew's Hospital show that during the years 1921 to 1924 inclusive seventeen patients died from haemorrhage attributed to gastric or duodenal ulcer. Blood transfusion has made it possible to deal with these cases under conditions which would have been impossible before the days of transfusion. For this condition some surgeons perform partial gastrectomy. It has seemed to me, however, that a less severe operation is wiser in patients who are almost moribund; and in the cases which have come under my care, partial gastrectomy would scarcely have been effective. In one there was a duodenal ulcer in the distal half of the second part of the duodenum, and on the posterior surface. On opening the duodenum a large callous ulcer was evident, and blood was seen trickling from under its upper margin. It was possible to undermine it with fine catgut and the bleeding was controlled at once. Gastro-jejunostomy was then performed. Blood transfusion was carried on by Mr. Keynes during the operation. Bleeding never recurred, and the duodenal ulcer healed, for I saw it at a subsequent operation. A gastro-jejunal ulcer supervened in the following year, and of this I will speak later.

In one case of persistent haemorrhage from a gastric ulcer the ulcer was so high that on opening the stomach and emptying it by suction it was impossible to reach and undermine the spot where the oozing was readily seen. It was reached by a long-handled cautery at a dull red heat and the bleeding was seen to stop. A gastro-jejunostomy was performed to prevent gastric retention and allow alkaline intestinal fluid to enter the stomach. I am not persuaded that either of these reasons is physiologically sound, but the patient—who for a month had been incapacitated and who at the time of the operation was moribund—has been working as a stevedore ever since.

Haematemesis due to acute ulcer seldom requires operative interference. Rest, medical treatment, and, if necessary, blood transfusion, has, in our experience, been sufficient to arrest the condition and recovery has followed; but with a chronic ulcer it is often otherwise. In spite of rest and blood transfusion the haemorrhages may continue with fatal result. In an increasing number of this class of patient we have been able to operate with success.

I have seen one case of syphilitic ulceration—a patient under the care of Dr. J. H. Drysdale. The patient suffered from gastric symptoms, and x-ray examination revealed the presence of a gastric ulcer. The Wassermann test was positive, and the symptoms cleared up with appropriate treatment.

In another case the diagnosis is not yet absolutely settled. In Fig. 15 a sacculus opening into the stomach close to the cardiac orifice is shown filled with barium emulsion. Inset is shown the cavity still filled with barium after the stomach had emptied. Severe haematemesis had occurred, presumably from this, and I had been asked to take in the patient. Dr. Hurst believes the condition to be ulceration in a diverticulum of the stomach. The patient was subsequently found to be suffering from phthisis—from which she is recovering, so that further opportunity for x-ray examination will probably be possible.

Five cases of gastro-jejunal ulcer have come under my care. Of these, one was the patient mentioned above, upon whom I operated after repeated severe duodenal haemorrhages extending over a month and increasing in severity. He was therefore very much debilitated when the operation was performed, and recovery was slow; whether this influenced the formation of the gastro-jejunal ulcer I am not prepared to say. Another case followed an operation which I performed for a perforated duodenal ulcer. The perforation was closed and a posterior gastro-jejunostomy made. Two years later an ulcer at the site of the stomach perforated. As far as I know these are the only two which have followed my own operations. In one other case I found strands of infected silk hanging into the lumen of the stomach from several ulcerated areas, and the whole circumference was thickened by the infection and granulation tissue surrounding the buried part of the silk. Operation for this condition is very difficult. There is always an inflammatory mass in the mesocolon surrounding the base of the ulcer. Often it is closely adherent to the colon, and separation of this is never easy. The stomach is freed from the mesocolon and the jejunum separated from the stomach; the opening in the jejunum may be closed and some variation of the Polya operation performed, or the jejunum may be divided and the operation completed as described by Sir Berkeley Moynihan.

X-ray examination with a barium meal has become a valuable procedure. Some years ago we were glad when positive evidence was obtained, but we did not expect too much from the method. If the surgeon and radiologist work together, evidence is obtained by a screen examination which is not always recorded on films or plates, and operation is now not often performed if there is no x-ray evidence of ulcer. Some patients are too ill for the examination to be made. If it is done by an unskilled radiologist the findings may be worse than useless, because inaccurate evidence is actually misleading. If ulceration is present, distortion of the outline of the viscus is sometimes seen (Figs. 1 and 2); a deposit of barium may remain in an ulcer crater (Figs. 5 and 13b). X-ray examination not only establishes the diagnosis, but also shows the position of the lesion, and knowledge is obtained of how much of the viscus appears to be normal, so that the type of operation may be considered, and perhaps definitely planned before the abdomen is opened. If a dual condition is present, as in Fig. 4 (duodenal ulcer with tuberculous glands) or Fig. 12 (gastric and duodenal ulcer), the surgeon is forewarned.

Of these skiagrams some have been reduced to a size appropriate for publication by Miss Vaughan in the Dunn Laboratories of the Professorial Units at St. Bartholomew's Hospital, and some by Kodak, Limited.

## A COMPARISON OF DRIED, EVAPORATED, AND FRESH COW'S MILK: AN EXPERIMENTAL STUDY.

BY

GLADYS ANNIE HARTWELL, D.Sc.

(From the Physiological Laboratory, Household and Social Science Department, King's College for Women, Kensington, London.)

At the present time there are many varieties of dried, evaporated, and condensed milks on the market. As it seemed possible that there might be fundamental differences between various sorts of dried and evaporated milks, a series of feeding experiments on animals have been made.

Sherman, Rowe, Allen, and Woods,<sup>1</sup> experimenting with rats, observed that "with bread and milk there was continued growth at a normal rate to full adult size." It seemed possible, therefore, to compare the different kinds of evaporated milk by feeding rats on each kind of milk and bread as the sole diet. According to a report of the Medical Research Council (1924) on the presence of vitamins in different varieties of milk, vitamins A and B are quite well represented, but vitamin C may be absent, or only traces present, in evaporated (condensed unsweetened) and dried milks.

Simmonds<sup>2</sup> concluded that the rat does not need the antiscorbutic factor for normal development, and that a diet of milk and bread might be expected to contain all the essential constituents of a complete diet for this animal. The experiments here described were started when the rats were just weaned (three weeks old), and were continued for twenty-two weeks, during which time several litters were born and reared. I regard it as a more searching test of the adequacy of a diet if gestation and lactation are included, and the experiment made not merely for the actual growth period. Mitchell,<sup>3</sup> in his article on the nutritive value of proteins, pointed out that the demands of growth, gestation, and lactation are all separate problems as far as the biological value of protein is concerned, and it is highly probable that this applies equally to all food factors.

## EXPERIMENTAL.

The experiments were made on the following lines:

## (a) Animals and Method of Experiment.

Rats were used in these experiments. They were all bred in the laboratory<sup>4</sup> and were all in equally good condition at the beginning of the experiment. Twelve animals, six males and six females, were fed on each diet. They were kept in a large cage together, so that breeding could take place as soon as the rats reached maturity. Each animal was weighed every day (except Saturday and Sunday) for the first few weeks, and after that, when growth was less rapid, only once a week. They were fed once a day. The females were removed to separate cages before the birth of the young. As far as possible, the method we adopt is to remove a doe from the large cage two or three days before the birth of the litter. She suckles her young for twenty-one days, after which she is returned to the large cage. If the young do not survive (as may happen when the diet is poor) the doe is returned to the large cage again when all her young have died. Rats have large litters, and our custom is to reduce the number of young to six on the second day, in order to prevent any undue strain on the mother rat, and to make the growth curves of the young comparable. The combined weight of even six babies towards the end of lactation may exceed that of the mother rat, but on a suitable diet she is capable of rearing her offspring without detriment to herself. From the second day onwards, the mother and her young are weighed daily; she is given ample food, all constituents of the diet being well mixed in the form of a paste.

## (b) Foods.

1. White bread bought from a baker was used, no crust being given. The bread was weighed each day old.

2. *Milks*.—The fresh cow's milk used was of good quality, was delivered in a bottle, and on standing always showed a large amount of cream. It was heated to 70° C. before being given to the animals. Of dried milks a well known brand (referred to as sample A in a previous paper<sup>5</sup>) was chosen as being a variety largely used by the general public. The brand of evaporated, non-sweetened milk chosen was selected because it appeared to be a popular article.

3. *Proportions*.—The evaporated milk was diluted according to the directions on the tin, and the specific gravity of this reconstructed food was approximately that of fresh cow's milk. With the dried milk 12 grams of solid were mixed with 100 c.c.m. of water. This is approximately the amount of solid required to imitate 100 c.c.m. of whole milk. My object was to use such amounts as would be used by the general public, following the directions given on the tin. Thus, when told to measure out

tablespoonful, etc., different people select different quantities—for example, some people give a generously heaped spoonful, while others will only fill it level. To avoid this difficulty, about twenty people were asked to measure the prescribed quantity, and these amounts were weighed. The average figure obtained in this way gave 12 grams of solid per 100 c.cm. of liquid.

**Actual Foods.**—The proportion given was 15 grams of white bread (crumb only) to 36 c.cm. of liquid, this being the amount of liquid which is conveniently soaked up by that amount of bread; also such a diet has been used with marked success during lactation. The animals were given plenty of food, the ration being increased whenever necessary.

### RESULTS.

All the animals grew well and the females produced litters at the normal time, but throughout the experiment it

FIG. 1.—Chart showing the growth curves of young rats (just weaned) fed on different diets.

was obvious that the rats fed on the evaporated milk were less fit than those fed on fresh cow's milk, or the dried milk. They were less firm to the feel and did not grow quite so rapidly; neither were their coats quite so thick. There was little to choose between the rats fed on the dried milk and the fresh cow's milk; but, if anything, those fed on the dried milk fared a little better—their coats were slightly thicker and more silky. A possible explanation may be that the milk used for the dried preparation was of better quality than the fresh supply, for Luce<sup>6</sup> has pointed out that the diet of the cow appears to be the main factor in determining the growth-promoting value of the milk. On the other hand, the experiment lasted for twenty-two weeks, and as one sample of milk was not used throughout any variation in composition might be found equally in any one of the three samples used.

### Growth.

Two series of experiments were made with regard to growth. The first were only continued for nine weeks, but the results were so striking that it was thought advisable to repeat them and continue them for a longer period in order to have data about gestation and lactation as well.

The composite growth curve of the male animals is shown in Fig. 1. It is impossible to give a composite growth curve for the females, owing to the rats becoming pregnant at different times.

All the rats grew well, but more rapid growth was exhibited by those which received the dried milk diet. Finally, those fed on the dried milk and those fed on cow's milk were of equal weight, while those fed on the evaporated milk did not attain to quite such a good weight. These rats received a mixed diet of bread and fresh cow's milk, supplemented by kitchen scraps.

It is not the object of this paper to show that the final weights of animals fed on bread and milk is not up to that of the control animals which were fed on a more varied diet, but to compare dried and evaporated milks with fresh cow's milk. It is, however, a point of interest to note that for the first few weeks the growth of the milk-fed rats is equal to that of the control animals receiving a good mixed diet—that is to say, for the first few weeks the rate of growth was maximal. It is also of interest that the first

FIG. 2.—Chart showing the weights of litters the mothers of which were fed on different diets.

curve to deviate from the normal standard is that of the animals fed on bread and evaporated milk.

### Reproduction.

Breeding took place at the normal time, and during the experiment fifteen litters were born to animals fed on bread and fresh cow's milk, fifteen litters also to those fed on bread and dried milk, and eighteen litters to those rats which received bread and evaporated milk. The greater number of litters born amongst animals on the third diet is probably due to the fact that fewer litters survived, and therefore the does returned to the males sooner than if they had suckled their young.

Thus all three diets must be regarded as suitable for the attainment of maturity and for fertilization.

### Gestation.

The average weight of the young at birth was not up to that of the stock animals. The average weight of a rat on the second day of life is 5.79 grams (figure taken from records in the laboratory). As will be seen from the accompanying table, none of the young of the experimental rats came up to this weight. It is interesting that, in this respect, the dried milk gives slightly better results (5.26 grams) than the fresh cow's milk (5.049 grams). Again, the failure to rear any babies of some litters is more marked among the mother rats fed on bread and cow's

milk and bread and evaporated milk (see table). Possibly this is due to the young being less fit, as well as of lower weight, at birth.

#### Lactation.

Lactation cannot be studied satisfactorily from this series of experiments. If the young are of low weight at birth, and the mother rat fails to rear them all, it is incorrect to assume that the diet is responsible. Obviously two factors are involved: the diet may be unsuitable for lactation, or the primary factor may lie in the poor condition of the young at birth—that is, a faulty diet during gestation. Since the young were all below average weight at birth, it is possible that the fault lay in the condition of the young, and not in the mother's milk supply. As will be seen from the table, some of the young were successfully reared, but not all.

To compare the three diets from the point of view of lactation, other experiments were made, as follows:

Stock does were selected and were given a good mixed diet during gestation. The milk diets were started as soon as possible after the birth of the litter; three mother rats were given each diet, and all were able to rear six young per litter. Examples of the growth curves of the young are given in Fig. 2.

It will be seen that the young whose mothers had the evaporated milk did not grow so rapidly as the others. Also, these babies were less fit—they were limp to the feel, and their coats were less good. However, they were all successfully weaned at the usual time.

Statistical Comparison of the Three Milks as Food during Lactation.

	Dried Milk (Sample A).	Fresh Cow's Milk.	Evaporated Milk (Sample G).
Average weight of one baby rat on second day	5.25 grams	5.04 grams	4.91 grams
Failures in rearing any one litter	2 failures out of 15 litters	6 failures out of 15 litters	7 failures out of 18 litters
Number of times all six young reared	6	3	4
Highest weight of one baby at 21 days	47 grams	42.75 grams	38.5 grams
Lowest weight of one baby at 21 days	30.33 grams	23.8 grams	25.0 grams

#### COMMENTS AND CONCLUSIONS.

From the experiments described in this paper it is obvious that dried and evaporated milks possess quite different dietetic values, and that the dried milk approximates more closely to fresh cow's milk than does the evaporated variety. Although only one sample of each kind of milk was used in this work, experiments previously reported prove that dried milks are superior to the evaporated ones as regards vitamin B content. To sum up—

1. The dried milk (Sample A)<sup>5</sup> compared with fresh cow's milk:

(a) The initial rate of growth of the young rats was more rapid, but the final weight attained was practically the same.

(b) The weight of the young on the second day was slightly better—that is, dried milk appears to be a better food for gestation.

(c) The suckling rats had thicker and silkier coats if the mothers were fed on the milk diet throughout their lives, but when the milk diet was only fed during lactation (that is, a good mixed diet given during gestation) there was no apparent difference in the sucklings.

2. The evaporated milk (Sample G)<sup>5</sup> as compared with cow's milk:

(a) The rate of growth of the young rats was less rapid and the final weight attained was less.

(b) The weight of the young at birth was less satisfactory.

(c) The weight of the young at weaning was lower. This applied equally to the baby rats of mothers fed on a good mixed diet during the gestation period, or on the milk diet throughout their lives.

Thus, the dried milk (Sample A) appeared to be quite equal in dietetic value to fresh cow's milk; if there was any advantage, it was in favour of the dried variety.

The evaporated milk (Sample G), however, compared less favourably with the fresh cow's milk.

It must be remembered, however, that a restricted diet, such as bread and any form of milk, is not as good as a mixed and more varied diet.

## THE ETIOLOGY OF PERNICIOUS ANAEMIA.

BY

A. CECIL ALPORT, M.D. EDIN., M.R.C.P. LOND.,  
FIRST ASSISTANT TO THE MEDICAL UNIT, ST. MARY'S HOSPITAL,  
PADDOINGTON.

SIRER Addison in 1849, in a paper read before the London Medical Society, described idiopathic anaemia, later called pernicious anaemia, a large number of theories have been advanced relative to its etiology. Hunter's hypothesis is that it results from oral sepsis with subsequent streptococci infection of the stomach, and there can be no doubt that pyorrhoea is at least a contributory cause. It may account for the toxin to which the combined lateral and posterior degeneration of the cord, occurring in about half the cases, is due. The latter is a true degeneration of nerve fibres affecting both the axis cylinders and the myelin sheaths, and not a sclerosis such as occurs in disseminated sclerosis. The fact that this degenerative change in the posterior and lateral columns occurs in other wasting diseases and may antedate the anaemia or be unaccompanied by the anaemia, lends weight to James Collier's argument that the toxin affecting the cord is not necessarily the cause of the anaemia, but that the anaemia and the cord changes may be the results of a pathological process responsible for more than one toxin. Other investigators are of opinion that pernicious anaemia is due to intestinal toxæmia. Herter blames the *Bacillus welchii*, while Adami suspects the *Bacillus coli*.

Hurst<sup>1</sup> says that it is now generally agreed that Addison's anaemia is caused by a haemolytic toxin produced by some infection in the alimentary canal, and states his belief "that this infection cannot take place unless free hydrochloric acid is completely absent from the gastric contents." He claims that the achlorhydria is neither caused by the same toxin which produces the anaemia nor is it secondary to the anaemia, but that it is an essential predisposing factor. He quotes Ryle and Bennett<sup>2</sup> to show that 4 per cent. of healthy young men have achlorhydria. It will be interesting to see whether these men in due time develop pernicious anaemia. Hurst sums up his views as follows: "The achlorhydria allows the bacteria which produce the haemolytic toxin, and which probably have their primary focus in the mouth, to pass through the intestines without being destroyed by the HCl which ought to be present."

I have endeavoured to approach the subject of pernicious anaemia from a new standpoint. I agree that an unknown toxin is probably the cause, but can find no proof of this. Therefore I have tried to postulate a theory with a non-toxic basis. It is possible that in this disease two independent processes are at work—an abnormal blood regeneration by the bone marrow and an increased blood destruction. Which of these processes is the primary one?

The general opinion seems to be that the main factor is the toxic effect upon the bone marrow, resulting in the production of immature cells, which are unable to resist the forces of blood destruction and become disintegrated in the blood stream or destroyed by the phagocytic cells in the liver, kidneys, and other organs. The hypothesis I prefer is that the primary factor is the phagocytic action of the liver and kidneys, and that the bone marrow change is secondary, the latter being due to an increased and urgent

demand for red cells to replace those destroyed. As a corollary to this I ventured to suggest to myself that the cause of the increased destruction was not an unknown toxin, but an unknown substance normally present in blood, the diminution or absence of which renders the blood increasingly liable to phagocytosis by the epithelial cells of the liver, etc., and I assumed this substance to be a constituent of bone marrow or a complex circulating in the blood.

In an endeavour to prove this theory, I attempted to extract an active substance by treating 2 kilograms of ox bone marrow with 80 per cent. alcohol, and later with 95 per cent. alcohol, and obtained no result. This was probably to be expected. I now applied this alcohol-fractional precipitation method, used by Banting in Toronto for the preparation of insulin, with slight modifications, to ox blood. I am indebted to Dr. Calvert of the Medical Unit for his assistance in the extraction.

#### Preparation of Extract.

To 8 litres of fresh ox blood 5 litres of 95 per cent. alcohol, previously cooled to 3° C., were added with constant stirring. The mixture was allowed to stand for two hours and filtered through thick Chardin paper. To the filtrate was added one and a half times its volume of 95 per cent. alcohol. The liquid, placed in a cool room overnight, was refiltered next day, giving a perfectly clear yellowish solution. The alcohol was distilled off *in vacuo* at a temperature of 45° C. in a water-bath. The following day the turbid liquid residue was redistilled *in vacuo* until the volume of the aqueous solution, the fat having separated out, was reduced to 250 c.cm. It was then filtered free from fat in a Buchner funnel and the residue shaken up in a separating funnel to dissolve any fat that might be left. After this the aqueous solution was made up to 80 per cent. with absolute alcohol and allowed to stand overnight in a cold room.

On the fourth day a thick yellowish solution had formed; it was decanted off and made up to 93 per cent. with absolute alcohol. This was allowed to stand in ice overnight. By the following day a precipitate had separated out. The 93 per cent. alcohol was siphoned off, about 50 c.cm. being left covering the precipitate. The latter was then centrifuged down, washed once with alcohol and once with ether, and then transferred to a vacuum desiccator over sulphuric acid.

The 8 litres of ox blood yielded 1.45 grams of a blood extract which I called "sanguinin." The substance is light brown in colour and very readily soluble in water. The solution, which is yellowish, I made up in the following dilution: 1 c.cm. of the solution = 10 mg. of sanguinin.

#### Experiments.

Intravenous injections were given into the marginal veins of the ears of two rabbits.

**Experiment 1.**—In the first rabbit 2 c.cm. (20 mg.) of sanguinin was injected. Fifty minutes after injection the blood sugar equalled 0.128 per cent., and ninety minutes after 0.140 per cent., showing that there was no appreciable amount of insulin present in the injection of blood extract given. Blood counts taken on the following dates showed:

1923.	Red Cells.	White Cells.	Haemoglobin.	Colour Index.
Dec. 4, just after injection ...	5,496,000	5,200	70%	0.64
Dec. 8, 4 days " " ...	6,410,000	7,400	65%	0.5
Dec. 10, 6 days " " ...	5,512,000	5,100	80%	0.78

In ninety hours the red corpuscles had increased by nearly a million per cubic millimetre, the whites by 2,200, and there was a fall of 5 per cent. in haemoglobin. The latter may have been due to there being too great a demand for haemoglobin to cope with the increase in the number of red cells. The general deficiency of haemoglobin was due to the animal being kept in confinement.

**Experiment 2.**—Into a second rabbit was injected 5 c.cm. (50 mg.) of sanguinin. Blood counts taken on the following dates showed:

1923.	Red Cells.	Haemoglobin.	Colour Index.
Dec. 17, just before injection ...	4,016,000	83%	1
Dec. 21, 4 days after injection ...	5,654,000	75%	0.66
Dec. 24, 7 days " " ...	6,280,000	90%	0.72
Dec. 31, 14 days " " ...	5,594,000	82%	0.82

Here again we find a fall in haemoglobin and an increase in red blood cells followed by a fall. It would appear that the sanguinin either temporarily stimulates blood formation or temporarily inhibits blood destruction.

A similar effect was observed on giving a series of intravenous injections to a patient with pernicious anaemia in a remission stage.

The patient was admitted to hospital on October 21st, 1922, with the following signs and symptoms: Lemon-yellow tinge of skin, glossitis, complete achlorhydria on three occasions; temperature rising to 100° F. at night; numbness and tingling in arms and legs, oedema of legs, and increasing weakness. All her teeth had been removed eight years previously, and her stools contained coliform bacilli only. The blood picture on admission was as follows: There was a great variety in the size and shape of the red cells, numerous megaloblasts, some showing mitosis. The red cells numbered 802,000 per c.mm., white cells 1,500, haemoglobin 20 per cent., colour index 1.2. Differential count: Polymorphs 32.5 per cent., small lymphocytes 51 per cent., large lymphocytes 7 per cent., eosinophils 5 per cent., myelocytes 3 per cent., hyalines 1 per cent.

The patient left hospital on December 15th for Christmas. She had greatly improved; the red cells numbered 2,436,000, white cells 1,400, haemoglobin 33 per cent., colour index 0.69. She attended afterwards as an out-patient, and periodical blood examinations were made without showing any appreciable difference in the blood picture.

As this seemed a suitable case for experimental purposes, owing to the blood being in a stationary condition, I gave her a series of intravenous injections of sanguinin at intervals of four days: 1 c.cm. (10 mg.) of sanguinin was given on September 30th and on October 3rd, 7th, 11th, and 15th. The blood counts, taken four days before, during, and subsequent to the injections, were as follows:

1924.	Red Cells.	White Cells.	Haemoglobin.	Colour Index.
September 26 ...	2,640,000	1,100	36%	0.68
October 7 ...	3,193,000	1,201	39%	0.61
October 11 ...	2,956,000	1,700	39%	0.66
October 15 ...	3,148,000	1,400	39%	0.61
October 22 ...	3,176,000	—	39%	0.61
October 29 ...	3,560,000	—	42%	0.6
November 5 ...	3,640,000	2,600	40%	0.55

Differential count: Polymorphs 29 per cent., large lymphocytes 10 per cent., small lymphocytes 59 per cent., eosinophils 4 per cent., fragile cells 2 per cent., and neutrophil myelocytes 1 per cent.

After the first injections she complained of sweating and of feeling tired, sleepy, and heavy in head, arms, and legs. After the later ones she said that they gave her fresh life and vitality and she missed them when they were omitted—probably a mental effect.

On December 1st, 1924, the count was as follows: Red cells 2,920,000, white cells 1,600, haemoglobin 40 per cent., colour index 0.69. Examination of the above figures shows that there was a rise in the red blood corpuscles of 1,000,000 per c.mm. in six weeks, followed by a fall in the succeeding three weeks. The white count of this patient has always shown a marked leucopenia, usually about 1,500 per c.mm. with a relative lymphocytosis. The colour index is characteristically high in the relapse and low in the remission stages.

Experiments with sanguinin (1 c.cm.) on blood pressure showed an immediate fall of about 20 mm. of mercury, but intravenous injections of distilled water (1 c.cm.) gave the same results, so the observation was of no value. I expected an increase in the blood pressure, on the assumption that there might be a percentage of adrenaline present in the blood extract. It is impossible to say how much of the undoubted improvement which has occurred in this patient since the injections were given is due to the sanguinin.

#### Conclusion.

The fact of importance which arises out of the above experiment is that an extract can be obtained from blood by means of the alcohol-fractional precipitation method. The substance is freely soluble in water, non-toxic, and has apparently some effect in increasing blood formation. The extraction process is a long and expensive one and the amount of sanguinin obtained very small. The failure to extract sufficient insulin to affect the blood sugar curve in the amount given to the rabbit is interesting, as is also the negative result obtained on examining the blood pressure.

It is not impossible that, by using other methods of extracting blood, further substances, probably of greater import than sanguinin, may materialize.

## MEMORANDA.

Memoranda:  
MEDICAL, SURGICAL, OBSTETRICAL.

**GALL STONES IN ADOLESCENTS.**  
THE accounts of cases recently published in the *BRITISH MEDICAL JOURNAL* describing the occurrence of gall stones in adolescents have elicited the fact that, at all events until fifteen years ago, no operation for this trouble had been performed on anyone under 21 years of age, and therefore the publication of another instance would appear to be justified.

S. E., a well built French girl, aged 15 years, was seized with abdominal pain, referred chiefly, but not solely, to the epigastrium, and of varying but gradually increasing severity. On the second day, at my request, Mr. C. P. Childe saw her with me, and forty-eight hours later the condition sufficiently resembled an "acute abdomen" to call for immediate operation. An appendix in a high position was the most natural conclusion, but a tentative diagnosis of gall-bladder trouble was made, with, however, less confidence than would have been the case had the patient been older.

Mr. Childe operated through an incision in the right semi-lunar line, which revealed acute cholecystitis without peritonitis. On opening the gall bladder, thickened bile with 150 small faceted stones and two larger ones, measuring  $1\frac{1}{4}$  and  $1\frac{1}{2}$  inch respectively, were found. On account of the infected condition of the gall bladder, cholecystectomy was performed, and recovery was uneventful. The only other point worthy of note is that the patient had been an inordinate eater of sweets from babyhood.

M. ASTON KEY, O.B.E., M.D.

Southsea.

THE note by Mr. C. M. Kennedy (May 9th, p. 882), relating a case of gall stones in a girl of 13, prompts me to send a few details of a somewhat similar case.

M. R., a girl aged 14 years, was sent to me by Dr. E. Gimson, D.S.O., of Witham, with a diagnosis, which he had made, of gall stones. The symptoms dated from two years previously, and there had been five attacks of severe colic in the preceding nine months and minor attacks of pain dating back to 1921. During one attack she was definitely jaundiced. When I saw her on March 24th, 1923, there was distinct tenderness on deep pressure in the right hypochondrium. I performed cholecystectomy for her a few days after, the gall bladder containing a large number of small stones.

Although this is the earliest age at which I have performed this operation for gall stones, I have had one or two others under the age of 20.

CECIL A. JOLL.

London, W.I.

CASES like that recorded below are of interest apart from their rarity. The patient was a Tamil boy, aged 12, with obstructive jaundice caused by gall stones and *Ascaris lumbricoides*. The case demonstrates the importance of this parasite as a cause of surgical conditions.

The patient was admitted to hospital on December 12th, 1923, under the care of Dr. P. H. Hennessy. He was in poor physical condition; both thighs were flexed on the abdomen; there was general abdominal tenderness, but no visible tumour. The temperature was normal; pulse 80. The tongue was coated and the bowels constipated.

His past history was as follows: At the age of 7 he suffered from sudden abdominal pain followed by vomiting. The pain increased in severity and lasted for about a week. He was at this time constipated and retention of food was difficult. He was taken to a dispensary and given "worm powders" and a dose of castor oil, and subsequently passed several *ascaris* worms. The pain subsided temporarily, only to return at monthly intervals. No swelling or distension of the abdomen had been noticed. During the three months previous to admission the attacks of pain had increased in severity; they were not constant in character, but were accompanied by fever and general weakness. Examination of the blood for malarial parasites was negative. A blood count showed: Polymorphs 69 per cent., small mononuclears 20 per cent., large mononuclears 5 per cent., eosinophils 6 per cent. No ova were found in the faeces, and the urine was normal.

On the day following admission the temperature rose to  $100^{\circ}$  F. and the patient had a rigor; severe pain was present in the umbilical region. A well marked globular swelling of the liver, felt protruding from beneath the under surface of the abdomen, was felt protruding from beneath the under surface of the abdomen. The urine contained bile, and the patient was slightly jaundiced. Dr. Hennessy diagnosed obstructive jaundice caused by gall stones in the common duct, complicated by *ascaris* worm in the biliary tract.

The patient was transferred to the surgical ward under my care on December 20th. Examination confirmed the diagnosis, and operation was decided upon.

**Operation.**—Under C.E., ether, and oxygen (Shipway) anaesthesia, the abdomen was opened by a right paramedian incision and the right rectus drawn outwards. The gall bladder was found greatly distended, the liver enlarged and of a bright red colour, with the lower border much thickened. There were no adhesions either in conjunction with the gall bladder or liver. The upper surface of the liver showed some scarring. The common bile duct was enormously dilated. Palpation of the common duct disclosed a number of stones, but palpation of the common duct failed to detect any stones, but palpation of the common duct disclosed a number. The abdomen was thoroughly packed off. The gall bladder was opened, emptied, and the wall was not appreciably thickened; no stones were found. The bile evacuated appeared normal. A drainage tube was fixed into the gall bladder and brought well outside the abdomen. The common duct was then opened over a stone, sufficiently passed upwards to the hilum of the left index finger was then easily passed upwards to the hilum of the liver and several stones were located. These were manipulated downwards and extracted. The finger was then passed upwards and the incision in the duct sutured over it. Both tubes were now brought out through the posterior sheath of the rectus—through a specially made incision. The rectus was replaced and a small split made in it; through this the tubes emerged. The gauze packs had already been removed and the peritoneal toilet attended to. The abdomen was then closed. The drains were removed on the fifth day. The fistula was completely closed on January 5th, 1924, and the boy was convalescent. Examination of the urine showed bile to be present each day from December 23rd to 28th, 1923, but absent on December 30th. There were no *ascaris* ova in the stools. The specimens were forwarded to Dr. Fletcher, Government pathologist, Kuala Lumpur, who reported as follows:

"I could find no eggs, but the fragment of worm was surrounded by a definite article, and there is no doubt that you are right and that it is a piece of round-worm."  
In a subsequent report Dr. Fletcher said:  
"I should think it probable that the *ascaris* was the cause of the gall stones, by acting as a contaminated irritating foreign body. The gall stones probably formed in the gall bladder."

C. BURGOYNE PASLEY, F.R.C.S.I.,  
Chief Surgeon, Perak, F.M.S.

## BILATERAL TWISTED OVARIAN CYSTS.

THIS case seems to be worthy of recording on account of its rarity.

A married woman, aged 45, was in good health until the beginning of March, 1925, when she noticed that she was getting stouter. On March 14th she had an attack of abdominal pain lasting a few hours; there was no vomiting, and the following morning she was well again. She consulted her doctor, and at a subsequent consultation the following facts were noted.

The patient was well nourished and looked well. She had slight exophthalmos with some enlargement of the thyroid and tachycardia (90). Menstruation had been quite regular up to Christmas, but she had seen four periods since then. The abdomen was distended, with bulging of the flanks and a well marked fluid thrill. A solid mass could be felt 2 to 3 inches above the pelvic brim rather to the right of the middle line. No pain or tenderness was elicited. By vaginal examination it was found that the pouch of Douglas bulged into the cervix. Bimanually a rounded swelling or two small fibroids in the cervix. Bimanually a rounded swelling could be palpated, which was thought to be separate from the uterus. The uterus itself was enlarged.

A diagnosis of fibroid uterus with an ovarian cyst or solid ovarian tumour and a large ascitic accumulation was made. The patient came to the nursing home on the following day, and during the forty-eight hours between the consultation and the operation the amount of ascites had markedly increased and the abdomen was tense. The pulse rate had risen to 110, and a systolic bruit was heard at the apex. Just prior to the operation the radial pulse could not be counted, but the patient seemed remarkably comfortable.

On opening the abdomen 14 pints of clear ascitic fluid was slowly evacuated and the patient's general condition improved. Two large ovarian cysts, each about the size of a grape fruit, were found. The right one was in the right iliac fossa and the left was in the pelvis, with many recent adhesions around it. They were both twisted, purplish in colour, and very tense, and many of the vessels running over them were thrombosed. Both were removed in the usual way. The uterus was enlarged to about two months' pregnancy and fibroid, but the condition of the patient did not warrant removal.

The interior of the cysts was lined by a warty growth which Dr. Walker Hall found to be a proliferating papillary ovarian cystoma, with much degeneration, accompanied by haemorrhage due to strangulation and locally malignant. The patient made an uneventful recovery; the bruit disappeared, and she left the nursing home three weeks after the operation.

Hereford.

J. AUGUSTIN PRICHARD.

## Reports of Societies.

### ERYTHROEDEMA.

At a meeting of the Edinburgh Medico-Chirurgical Society on May 6th, with Sir DAVID WALLACE, the President, in the chair, Dr. J. S. FOWLER read a paper on erythroedema and described four cases which had come under his notice.

Dr. Fowler referred to the rarity of the condition in this country, but pointed out that, owing to the fact that the symptoms of the disease did not always form a typical syndrome, it was probable that the condition would be found to occur more frequently if a careful watch was kept for it. He referred to the frequent occurrence of the condition in Australia: Swift of Adelaide was the first to draw attention to the condition, and he named it "erythroedema." Jeffreys Wood of Melbourne, and Bilderback and Weston in America, described further cases, the latter terming the condition "acrodynia." A few cases had been recorded in England by Thursfield, Parkes Weber, and Paterson, and by Feer of Zürich—the only Continental reference. Dr. Fowler then described the four cases seen by him since 1923. In none of them was there any history with regard to diet or antecedents which might throw light on the etiology; the home conditions in all were above the average. The chief clinical features as shown by these four cases were as follows:—*Age:* Dr. Fowler's cases were two boys aged 2 years and 13 months respectively, and two girls aged 2 years 1 month and 13 months. The disease, however, might occur between 4 months and 4 years, and appeared to affect both sexes equally. *Course of Prognosis:* Three of Dr. Fowler's patients died, but this was exceptional; most recovered after a protracted illness lasting up to a year. In Jeffreys Wood's 91 cases only 5 died, mostly from bronchopneumonia. *Symptoms:* The striking appearance of the hands and feet was pathognomonic of the disease, and the red nose and cheeks were often seen. Profuse sweating accompanied by rashes and intolerable itching was invariable. The thoroughly wretched condition of the patient was most striking, and was associated to some extent with the characteristic insomnia. Dr. Fowler thought that this insomnia was not entirely due to the itching but was a direct symptom of the disease, resembling the insomnia of encephalitis in some cases. Loss of teeth was common, and the chief nervous symptom was muscular atony. The frequent pulse without pyrexia and the high blood pressure were probably constant features. Dr. Fowler found no special changes in the blood or cerebro-spinal fluid, and the Wassermann test was negative in all cases. Nothing was definitely known as to the etiology of erythroedema. On account of a distant resemblance to pellagra, a diet deficiency had been suggested, but in the cases described the feeding and home surroundings had been usually quite satisfactory. There seemed no doubt that for some reason or another erythroedema had become more common since the influenza epidemics of 1918; Feer had suggested some upset of the vegetative nervous system. The treatment was not satisfactory. Attention to the diet, and painting the gums with 1 per cent. chromic acid to prevent secondary infection, were the main points. Feer stated that benefit resulted in one case from large doses of atropine, and in another from calcium lactate.

*Case 1.*—A female, aged 2 years and 1 month, had been quite healthy until an attack of vomiting with feverishness of fourteen days' duration, four months before admission. Since then she had been very miserable, cross, and sleepless, refusing food, and suffering from an itchy rash over the body. During the last few weeks her fingers and toes had become thickened, red, and clammy. She had wasted, could no longer walk, and when sitting in bed always fell forward on her face. On admission the child was miserable, whined constantly, and seemed in pain if touched. She was fairly well nourished, her cheeks and nose were bright red, and her muscles very soft and flabby. She lay either with her face buried in the pillow or with her head resting on her knees. A punctate erythema resembling a sweat rash was scattered over the body, and she sweated profusely. The hands and feet were swollen, livid red, with thickened fingers and toes covered by sodden, desquamating skin which felt cold but did not pit on pressure. The discoloration had an ill defined margin and extended to just above the wrists. The hair was short, ragged, and scanty. The heart and lungs were healthy, and there were no signs of rickets. The leucocyte count was 12,000. There was great muscular hypo-

tonia, with no true motor paralysis; the knee-jerks were much diminished, and sensibility to pin-pricks impaired. While in the ward she showed marked sleeplessness, very poor appetite, and slowly wasted. Cutaneous irritation was marked; she rubbed at her skin and pulled out tufts of her hair. The temperature was not raised, but the pulse varied from 120 to 150. The blood pressure was high—100 to 120 mm. mercury. With no apparent previous changes in the gums three incisor teeth loosened and fell out; this was followed by a very bad stomatitis which showed no tendency to heal. During her eighth week in hospital she developed bronchitis and a streptococcal infection of a finger-nail, and died of septicæmia.

*Case 2.*—A male, aged 2 years, was admitted on account of stomatitis and loss of teeth. Seven weeks previously he had become moody, fretful, and irritable. Three weeks later the hands became irritable, red, and swollen, while a speckled rash appeared over the body. He then began to pull tufts of hair out, and play with his teeth, which fell out. There was no insomnia. He was very ill on admission and died a few hours later from bronchopneumonia. The hands and feet had the same appearance as in Case 1; the body was covered with sudamina, the muscles were very soft and lax, and the gums were sloughing deeply.

*Case 3.*—In a female, aged 13 months, the first symptoms were constipation followed by diarrhoea. She became flabby and very cross, and sat with her face resting on her knees. She slept little and had a very poor appetite, but was always thirsty. The hands and feet had become red and swollen. On admission she was fretful, the nose and cheeks red and mottled, the hands and feet swollen, dark red, and moist, and the muscles very lax. The pulse was 160, the blood pressure 115. Several teeth fell out while she was in hospital, and the gums became ulcerated, exposing the permanent teeth and leading to the loss of one of these also. The symptoms were the same as in Case 1, only less severe. After five weeks in hospital she was removed by her parents, who were leaving the town, and had since been lost sight of.

*Case 4.*—In a male, aged 13 months, illness began at the ninth month with bright red rashes on the body. He became very limp, but was not fretful. He sweated a great deal, and the hands were so itchy that they had to be bandaged to prevent scratching. His symptoms had never alarmed the mother, but two days before his death he had erythematous rash, was very flabby, and his hands and feet were red and swollen. Next day his temperature was 100°, and on the morning of Dr. Fowler's visit he had suddenly collapsed. He was moribund when seen, the temperature was 105°, and the pulse was uncountable. He was sweating profusely; one incisor tooth was loose. He died half an hour later; no explanation of the sudden collapse and fever was found.

Dr. JOHN THOMSON said that his own experience of erythroedema—apart from the cases which Dr. Fowler had shown him—consisted of two good-class children aged 2 years 4 months and 17 months respectively. Their symptoms were those which Dr. Fowler had described, but they were milder cases and showed no loss of teeth. They were both treated with cod liver oil and cod liver oil in the diet, and autogenous vaccine injections. Both recovered and had remained well.

Dr. CRANSTON LOW suggested the possibility that the teeth condition might be the primary one, and the source of absorption. From the description of these cases the skin condition seemed to him to resemble what might be called glorified chilblains: in his opinion chilblains were due to the absorption of some toxic substance—most likely from the bowel.

Dr. FOWLER agreed with Dr. Cranston Low about the resemblance of erythroedema to chilblains, and thought there might possibly be some relation between them. He did not think that the teeth could be the primary cause, as disease there was usually a late symptom. An early x-ray examination might, of course, show a primary focus, and in any future case this would be looked for.

### Bronchial Fibrosis in Children.

Dr. CHARLES McNEIL then read a paper on fibrosis of the bronchi and lungs in childhood following bronchopneumonia. He referred to the fibrotic conditions of the lung consequent upon primary interstitial pneumonia produced by tuberculosis, syphilis, the duct diseases, and foreign bodies in the bronchus. He drew attention to the fact that though widespread alveolar pneumonia was a common condition, interstitial inflammation followed by fibrosis rarely resulted from it. Inflammation of the bronchi or pleura was more commonly followed by permanent peribronchial and subpleural fibrosis. With regard to the latter condition, one striking feature was the good general health usually found with widespread physical change in the affected lung. His paper was based on six cases in which the fibrotic changes were definite and demonstrable, and on twelve others in which the fibrosis was indefinite, but where the other clinical features justified their inclusion in the same

group. Referring to the history of the disease, he paid tribute to Laënnec's work in describing the fibrotic condition of the lung associated with bronchiectasis. In Laënnec's four cases the history was life-long, but the condition was compatible with long life and fair health. He apparently considered the bronchial dilatation as the primary factor. In 1833 Corrigan of Dublin described three autopsies, and said that the primary change was the increase of fibrous tissue, bronchial dilatation resulting from the traction of this contracting fibrous tissue. In addition he described the displacement of the heart to the affected side. Dr. McNeil referred to the monograph by Clark, Hadley, and Chaplin, differentiating between simple and tuberculous fibrosis by the good general condition of the patients, the absence of tubercle bacilli from the sputum, and the massive fibroid change in one lung. In most cases the originating illness had not been observed, but he believed that it was always a bronchopneumonia. In three of his cases the bronchopneumonia was primary and in three associated with measles. The immediate sequelae of such cases were the persistent hacking cough and failure to recover former vigour, but alarming thinness was uncommon. In the early months relapses with fever and exacerbation of cough occurred. The cough usually began on waking and lasted for half to one hour. Sometimes it occurred during the night and vomiting was frequent. Cough was apt to follow slight exertion or crying. The sputum in Dr. McNeil's cases was scanty and viscid, occasionally streaked with blood, and tubercle bacilli were never found. The breathing readily became hurried on exertion. In his six complete cases the fibrosis was always unilateral—left-sided in five, and right-sided in one. Flattening of the affected side, dullness, and faint or loud bronchial breathing with accompaniments were found in all cases. X-ray examination confirmed the physical findings and demonstrated the displacement of the heart and trachea. Dr. McNeil showed lantern slides from photographs of his patients and of x rays of their lungs. With regard to bronchiectasis, he suggested that on clinical grounds paroxysmal cough and cavernous breathing were not enough. A copious expectoration and probably also the presence of clubbing of the fingers and cyanosis should be present before the term "bronchiectasis" was justified. The general health in those six cases was found to vary. Under 5 years old, nutrition suffered little, after 5 years periods of good and bad nutrition, according to the severity or otherwise of the symptoms, occurred. In later childhood average energy and activity was shown. Clubbing of the fingers, cyanosis, and dyspnoea did not show in these six cases. Recurrent attacks of pneumonia occurred, but Dr. McNeil's experience had been that they were less severe and prolonged than usually occurred in an undamaged lung. These patients also resisted well ordinary infectious diseases. With regard to the possibility of infection by tuberculosis, Dr. McNeil thought that because of the amount of fibrous tissue these patients resisted tuberculosis more readily. If the general condition was good, and especially if in addition the tuberculin reaction was negative, the presumption was against active lung tuberculosis. Dr. McNeil then described his incomplete cases as being identical with the classical type with nocturnal cough, except for the absence of definite consolidation and contraction of the lung. The x-ray picture was blurred and streaked and the changes were bilateral. The signs of bronchial or pulmonary catarrh, however, were confined to one area of lung and remained so. He showed slides of microscopic sections of lungs of children who died at a very early stage in acute bronchopneumonia, in which congestion of the peribronchial tissue and cellular proliferation and oedema of the interalveolar tissue were seen. The prognosis in these cases, as had been indicated, was usually good, but treatment to reduce the fibrosis was not promising. Dr. McNeil had used iodides and thyroid extract without definite results. For the catarrhal condition and cough, complete rest in bed, warmth, fresh air, and sunshine were the sovereign remedies. Various expectorants and antiseptics might be used with benefit, but postural coughing and autogenous vaccines in Dr. McNeil's six cases—in which probably no real bronchiectasis was present—were of no value.

Dr. FOWLER remarked on the good general health of these

patients. He thought that in the majority of the cases the affection was primarily in the pleura. Dr. RITCHIE said that the massive involvement of one lung and the healthy condition of the other, along with the radiograms, were the most useful signs in differentiating between this condition and pulmonary tuberculosis. Dr. GUTHRIE referred to the condition being produced by a foreign body. In none of Dr. McNeil's cases which Dr. Guthrie examined could any sign of a foreign body in the bronchus be found. Dr. MATHEWSON described two cases in older children in whom an early systolic aortic murmur was heard. He suggested this might be due to mechanical traction on the root vessels of the neck. Dr. McNEIL, in reply, agreed that some cases might be pleural in origin. He had not found any aortic murmur in his cases.

### GASTRIC AND DUODENAL SURGERY.

A MEETING of the Section of Surgery of the Royal Society of Medicine, with the President, Mr. H. J. PATERSON, in the chair, took place on June 3rd, when Dr. CHARLES H. MAYO (Rochester, Minn.) gave an address on gastric and duodenal surgery.

Dr. Mayo said that operations to relieve pyloric obstruction were devised and practised early in the history of modern surgery. The first of these was the operation of pylorotomy by Billroth's first method. In 1882 Hartmann and other Continental surgeons were practising this operation, which gave great relief in successful cases, but was attended by a very high mortality from leakage at the dangerous triangle where the duodenum was united to the suture line in the stomach. To Nicolodena belonged the credit for devising the first short-circuiting operation or gastro-enterostomy, which avoided the difficulty of dealing with this triangle. This was followed by the introduction of Billroth's second method of pylorotomy, in which the cut stomach was completely sutured and the open end of the duodenum anastomosed to a fresh opening in the stomach. Owing to the fact that the duodenum was an unsatisfactory material for suture, the operation of Billroth II was superseded by operations designed to dilate the pylorus, such as those of Loreta and Ramstedt; the latter was still extensively practised to this day for the congenital form of pyloric stenosis in infants. In 1892 Finney began to perform pyloroplasty, an operation which he continued to perform with great success until three years ago, when it was modified. About the same time came the mechanical aid to anastomosis—Murphy's button, Mayo-Robson's bone hobbin, Senn's decalcified bone plates, etc.; all these had now been abandoned in favour of plain suture. The next and very great advance in gastric surgery was the advent of the Polya operation, which was extensively practised at the present time throughout the surgical world, either in the original form, in which the anastomosis was a posterior one, or now oftentimes in Balfour's\* modification, in which the loop of jejunum was brought in front of the splenic flexure of the colon and the anastomosis was consequently an "anterior" one, although the same opening in the stomach was employed for the stoma. It was remarkable that the small remainder of the stomach became dilated after this operation, so that in time the organ resumed a size approximating to the normal. Balfour's modification, now regarded as the more satisfactory operation of partial gastrectomy, whether for ulcer or for cancer, was originally designed to avoid the necessity for the opening in the transverse mesocolon near the mid-colic artery; for it was thought that the liberal blood anastomosis in that region was responsible for the very rapid dissemination of cancer which sometimes followed the original procedure. The success of the operation of gastro-enterostomy had led to its abuse by performing the operation when no ulcer was demonstrable, although symptoms simulating ulcer might have been present. The reflex causes of gastric symptoms were now more generally recognized, and failures from this cause less frequent. Other causes of failure which the speaker had had to deal with arose from an improper site of the anastomosis, a long loop, and ulcer at the anastomosis. In

\* Generally known as the Mayo-Polya operation.

three cases, on reopening the abdomen after a primary operation by another surgeon, he had discovered the anastomosis in the ileum at 9, 10, and 18 inches respectively from the ileo-caecal valve. A long loop was now recognized as being liable to give trouble from angulation or kinking, but the direction of the stoma was a matter the importance of which was still insufficiently appreciated. It was only rarely that the first piece of the jejunum ran directly down from the duodeno-jejunal junction; more often the first turn or loop was in the region of the spleen. There was sometimes trouble with the third loop of the jejunum in the region of the gall bladder. Gastro-jejunal ulcer had become less common since the adoption of the catgut suture for both layers; the majority of anastomotic ulcers were associated with the presence of an unabsorbable suture. At the Mayo Clinic it was remarked that the cases that progressed well from the first generally continued to do so; further trouble was to be expected chiefly in the cases which did not make rapid improvement immediately after the operation.

Regarding the choice of operation to suit the individual case of ulcer of the stomach or duodenum, Dr. Mayo held very strongly that the operation of partial gastrectomy should be reserved for the large ulcer of the body of the stomach, the type that was apt to become cancerous. He had seen extensive resections of the stomach with a portion of the duodenum performed for small ulcers of the pylorus or even of the duodenum, neither variety being of the type that became cancerous; this he regarded as quite unnecessary and unjustifiable. As regards the results of the surgery of gastric and duodenal ulcer, records of 1,000 consecutive cases at the Mayo Clinic showed that 90 per cent. were successful, but 10 per cent. were failures either from haemorrhage, obstruction, or gastro-jejunal ulceration; the incidence of the last had been reduced from 4 per cent. to 2 per cent. by the use of catgut exclusively. The common etiology of ulcer of the stomach or duodenum was expressed by its name, "peptic ulcer," but ulcers did occur in cases of complete achlorhydria which could not be so explained, since no hydrochloric acid was present to activate the pepsin. Such ulcers were associated, he thought, with the innervation of the stomach; the achlorhydria was a part of a general alkalosis throughout the body, accompanied by various symptoms of nervous derangement. The ulcer in achlorhydria he therefore regarded as "trophic." Such ulcers rarely or never perforated. Ulcers could also be produced by large doses of drugs or of bacteria, and ulcers in the duodenum had been experimentally produced by diverting the normal alkaline pancreatic secretion into the lower ileum, but none of these forms of ulceration was permanent; so soon as the stimulus that produced them was withdrawn they healed. The late Dr. John Hunter, in his study of the sympathetic system, pointed out that many muscles possessed the power of fixation only. Such muscles were apt to go into a state of spasm and were responsible for pylorospasm, cardiospasm, and certain cases of hour-glass stomach. The essential feature of such cases was a derangement of the central nervous system. In some cases a similar spasm was observed in the small intestine, and led to the bulging of the mucosa through the muscular coat at the points of entrance of the vessels, thus paving the way to the formation of permanent diverticula. He had actually observed this occurrence during an operation.

Returning to the question of the choice of operation, Dr. Mayo pointed out that gastro-enterostomy was not very successful in dealing with haemorrhage from duodenal ulcer, which was a symptom in 24 per cent. of such cases although serious haemorrhage only occurred in about 8 per cent. He concluded by referring to the necessity for travel and seeing new methods and hearing new theories if medical men were to avoid having a closed mind and becoming stereotyped in their work. In surgery it was essential to keep constantly in mind the ideal of achieving the desired result with the least possible damage to the patient.

A number of lantern slides showing the work at the Mayo Clinic, and Drs. William and Charles Mayo at their home, were shown by the President, and the meeting con-

cluded after Dr. Mayo had replied briefly to a vote of thanks, proposed by Sir JAMES BERRY, seconded by Mr. NICHOL, and carried with acclamation.

## PARASITIC SKIN DISEASES COMMON TO MAN AND DOMESTIC ANIMALS.

A MEETING of the Section of Comparative Medicine of the Royal Society of Medicine was held on May 27th, Mr. F. HONNAY, the President, in the chair.

Dr. J. H. SEQUEIRA read a paper on the parasitic diseases of the skin communicated to man from the domestic animals. The paper was illustrated by lantern slides. This question, he said, was a most interesting one, and although a specially rich field could be found among such diseases from tropical and subtropical countries, he proposed to confine his remarks to those occurring in Britain. In recent years it had been found that so-called "eczema" was frequently due to micro-organisms and often was really scabies; this was true both for man and animals. He divided the skin diseases into four classes: (1) Animal parasites—due to the Sarcophagidae and Demodicidae. (2) Moulds—due to ringworm fungi. (3) Micro-organisms transmitted from animals, including such diseases as tuberculosis, anthrax, and glanders; and parasites inoculated by insects or deposited on the skin in their faeces. (4) Virus diseases such as cow-pox, foot-and-mouth disease, and, possibly, molluscum contagiosum.

*Animal Parasites.*—The most important of the mange mites from the point of view of intertransmissibility was *Sarcoptes scabiei*. No differences were found between those forms in man and those in animals—except possibly in point of view of size. Some of the animal forms were found not uncommonly in man; but in general, infection of the human subject was difficult. Other genera than this were found in animals, but were peculiar to them—with the exception of the mange mite of the cat, *Notodectes cati*. McDonald had recently drawn attention to the infection of a class of veterinary students from a diseased horse which was being dissected, and had given considerable details as to their symptoms and treatment. Cases from dogs were not infrequently reported, and occasionally also from the camel. *Demodex folliculorum* was generally considered a harmless human parasite, but it had been suggested that it might convey bacteria to the skin and be the cause of a form of "ring" impetigo. It appeared to be much more pathogenic in the domestic animals. A final animal parasite of interest in this connexion was the extremely rare subcutaneous hydatid, only two cases of which had been reported.

*Ringworm.*—Many species of ringworm fungi existed in man and animals, and there was a great deal of intertransmission of the various species. Two genera of fungi, *Microsporum* and *Trichophyton*, were responsible for ringworm, and one, *Achorion*, for favus. Many strains of these parasites existed, and the lecturer showed illustrations of ringworm in man caused by infections derived from cat, dog, and calf, that from the calf forming concentric characteristic rings. Dr. Sequeira quoted the case of a "lather boy" in a barber's shop who had contracted the disease from a customer (the fungus being of animal origin originally). The boy developed a lesion on his finger, which passed the disease on to the face of other customers. The forms from animals might be scaly, vesicular, or pustular—the last often developing into follicular or perifollicular abscesses. Favus was uncommon in Britain, and was usually seen in Polish immigrants and those who came into contact with them. It formed a distinct cup-like lesion ("favus cup"), and attacked both hair and skin, leaving very deep scars. It was not a common animal parasite, but evidence had been produced to implicate the mouse as a source of infection, and the infective chain was probably: mouse—cat or dog—man.

*Bacterial Diseases.*—Warty tuberculosis was the commonest form found due to inoculation, and was occasionally seen in those making post-mortem examinations or coming into contact with tuberculous discharges of human or animal origin. It formed a characteristic lesion with a scarified centre, a warty intermediate zone, and a purplish periphery. Anthrax was familiar as a malignant pustule, which, owing to public health measures, was now much less serious than in the past. It was curious that in negroes it appeared to be much less malignant than in Europeans. Glanders was now almost extinct in this country, and he personally had never seen a case.

*Virus Diseases.*—Dr. Sequeira referred to a case of cow-pox occurring in 1913 in a man from direct contact with cattle. The patient was 55 years of age, and had not been vaccinated since infancy. Cases were not uncommon of mothers being

infected by scratches from their own newly vaccinated children. Foot-and-mouth disease was another subject of great interest in connexion with this subject.

The PRESIDENT drew attention to the increasing importance of the animal diseases from the point of view of human health, and gave instances of cases which had come under his own notice.

Dr. A. STOKES raised the question whether actinomycosis could be considered as one of the diseases of animals directly transmitted to man.

Dr. T. W. M. CAMMION drew attention to a source of sarcoptic mange in man which was very often overlooked—namely, cattle, which were very extensively infected, at least in some parts of Britain, and were a source of "dairyman's itch." The parasites of the genus *Demodex* were of great interest. Mr. Stanley Hirst of the British Museum had recently published a most exhaustive monograph on the genus, in which he showed that the human species was not the same as that found in dogs; and that, in fact, most animals had their own peculiar species—unlike the mange mite *Sarcoptes scabiei*, only strains of which existed in the various hosts. It was very improbable that man could be infected by animal forms. At the same time the parasite must to some extent at least be contagious, otherwise one would be compelled to believe in spontaneous generation. The relationship of "follicular mange" to *Demodex* was a very vexed one. Many people believed that a micro-organism was the cause of the disease and the mite merely the carrier. He had often found the parasite in apparently healthy dogs, and it was probably as common as the human form was reported to be, and probably as little pathogenic as a rule. It was possible that the parasite merely found a convenient ground to develop in the primary lesions developed by the micro-organisms, but a *post hoc, ergo propter hoc* attitude must be rigidly avoided. He was very doubtful if actinomycosis, which was rapidly becoming a name for a symptom and not a disease, was ever transmitted from animals to man.

### AORTIC DISEASE.

At a meeting of the Devon and Exeter Medico-Chirurgical Society held on May 21st, the Vice-president, Dr. R. WORTHINGTON, in the chair, Dr. G. L. THORNTON read a paper entitled "A few reflections on aortic disease," based on over five years' study of ex-service men.

Dr. Thornton laid emphasis upon the point that any conjectures and conclusions were purely personal, and in no case represented necessarily the considered views of the Ministry of Pensions. Aortic insufficiency offered special attractions as regards wealth of material for study. The ages of the patients ranged from the early twenties to 65 and upwards, the extremes being supplied for the most part by ex-naval ratings, the discharged "boy" and the chief petty officer, both engaged in active service at ages which were exceptional in the army. After referring to the six groups of aortic disease distinguished by Osler, Dr. Thornton added that in his paper he would limit himself to the endocarditic group (acute rheumatism), the syphilitic, and the arterio-sclerotic. The endocarditic group had supplied every degree of the disease from the case discovered accidentally, the condition causing little or no embarrassment at the time, to that of severe degree with rapidly failing compensation. In the milder cases had occurred what might be described as the "elusive, aortic diastolic murmur," and various clinical details were given in illustration of this and other conditions. Several examples were noted of the arterio-sclerotic type and age, the patients having failed rapidly after four or five years' service in the war, and it might be conjectured that the myocardium must have been exhausted before demobilization. Naval cases comprised the majority of those in which the condition had become rapidly worse since the completion of their service. The arterio-sclerotic type of case raised the question how far the increased tension had in itself a mechanical effect upon the aortic valves, and a great deal of evidence was forthcoming in this respect. In a series of cases of nephritis carefully analysed only 2 per cent. showed lesions of the aortic valve, although blood pressures as high as 260 were registered. Dr. Thornton remembered

two high readings, one approximating 300, in men less than 30 years old, who at present showed no sign of insufficiency at the aortic valve although the condition had been under observation for several years. In both cases, nevertheless, the arteries were thickened, and degenerative changes might well be expected in the valves later in life. There seemed, however, to be no authority for suggesting the existence of any condition of the aortic orifice comparable with temporary regurgitation at the mitral valve, either as the result of strain or of the myocardium being weakened by acute illness. Although strain had a powerful influence for evil on the aortic valve, it would appear necessary to admit the presence of some contributory agent, such as syphilis or atheroma. In some cases a diastolic murmur heard over the aortic area had tended to disappear, but Dr. Thornton could recollect no case where some evidence did not persist pointing to valvular insufficiency, and as regards severity of a case the elusive diastolic murmur had been noted at both extremes of the scale. In several instances the Flint murmur had been detected when the aortic diastolic murmur was either absent or too faint for recognition. Not infrequently such a case had been first diagnosed as pure mitral stenosis.

With regard to symptoms, the general appearance of the patient had been frequently of great service in estimating the disease, and the nature of the cardiac pain gave valuable information, ranging as it did from a mere slight stuffiness in the throat in the milder cases, to the definite angina occurring in the later stages of atheroma. Intermediate degrees were associated with pain across the chest at the level of the nipples, especially the left breast. This distribution seemed to be often compatible with a large but otherwise well compensated heart. On the other hand, the most severe and anginal type of pain had been noted in hearts where pressure from enlargement could be discounted as a factor in the production of pain, and Dr. Thornton believed that the prognosis would be bad in any case, even without the ominous facial appearance, so often present, as a guide. The actual extent of the transverse enlargement of the heart or the position of the cardiac impulse had not provided any sure line of demarcation, but in the young patient, with a past endocarditic history of many years, rough guides could be formulated by calculating the hypertrophy which maintained the compensation and relating it to the apparent age of the affection. With regard to the Flint murmur, if there was a possibility of stenosis of the mitral valve being associated with aortic disease, the case must inevitably be considered grave, but in those cases where the mitral valve was healthy no indication could be drawn from the presence or absence of a Flint murmur. This murmur had been observed in nearly 50 per cent. of the cases, apart from those where there was evidence of the existence of mitral stenosis. It was unnecessary to consider the import of an apical systolic murmur, which was different in pitch from one heard at the base, and more especially if there was wide external conduction of the former murmur. Dr. Thornton alluded to the elusiveness or varying degrees of intensity of the diastolic murmur, and remarked that conclusive evidence of aortic regurgitation might exist without there being a constant diastolic murmur. Although the complete absence of an aortic second sound, either in the neck or at the base, was undoubtedly of serious significance, yet care was necessary before classifying the case as mild when the sound was clearly audible. The second sound had been present, though not necessarily at every examination, in at least 40 per cent. of the cases, and in many of these the symptoms had been so severe as to negative the presumption that the presence of the sound could be taken to indicate efficient closure of the valve, even if it was admitted that the second sound at the aortic area originated solely at the aortic ring. Still greater caution was necessary in atheromatous and syphilitic cases where there might be interruption of the innervation and local circulation of the myocardium. Auscultatory findings must be collated with the symptoms generally. Blood pressure readings had been very variable, though in the majority exceeding 140. Apart from high figures and the wide separation of the systolic and the diastolic readings, more information was derived when repeated routine examinations showed that

the pressure was steadily falling—the sign of a failing myocardium. Oedema, except at the ankles, and pulmonary stasis had been rare, even in the most severe cases, and albuminuria had rarely exceeded a trace, except when the aortic reflex was associated with nephritis. Nervous symptoms had not been prominent, but when present had always been found to be associated with advanced aortic disease and failing compensation. Actual mental disease, necessitating removal to a mental hospital, had been less common than would have been expected.

The prognosis seemed to be particularly difficult in aortic disease; once the diagnosis was established no case could be regarded lightly, either in the present or from the point of view of the future, bearing in mind the circulatory changes of middle life. No single symptom appeared to give a definite lead for forming an opinion; the guidance must be drawn from the sum total of the subjective and objective findings, and not infrequently in aortic disease the condition was clearly shown by the face of the patient. Dr. Thornton expressed his indebtedness to the Director-General of the Medical Services, Ministry of Pensions, for permission to publish his paper.

The CHAIRMAN referred to the pessimistic prognosis which had been attached to cases of aortic regurgitation in his student days. He was glad to learn from the paper that the disease was compatible, in some cases, with many useful years of life, and he quoted a parallel case of an old friend in medical practice.

Dr. WILLIAM GORDON was much interested in the elusive aortic diastolic murmur, which might be subclassified into the true elusive murmur which all observers failed to find from time to time, and the murmur which was easily missed on auscultation. He showed a form of telescopic single stethoscope which, when drawn out to full length, lengthened the wave and proved very useful in doubtful cases. Touching on prognosis, Dr. Gordon quoted Allbutt, who, writing on aortic disease, and from a long experience of an industrial city, gave twelve to fifteen years as the outside expectation of life from the time the murmurs were first noticed. The longevity peculiar to Devon, which Dr. Gordon's statistics had proved in association with other disabilities, had probably a bearing on cardiac survival also. Rheumatic cases certainly survived longest, but syphilitic affections of the aortic valve were very grave unless treated energetically from the onset, and in this connexion he strongly advocated sodium iodide and deprecated injections of salvarsan. As regards congenital cases, the French had considered that the origin might be due to intranatal acute rheumatism. He also quoted a "traumatic" case, where the history pointed to a severe blow over the chest from a football. Finally, he counselled the meeting not to desert such valued friends as the iodides had proved themselves in treatment; whilst, in the literature of cardiac disease, *The Senile Heart*, by Balfour, would still give profitable reading.

Dr. H. JONAS mentioned his personal experience of an elusive aortic murmur, where the remainder of the cardinal symptoms of regurgitation were quite obvious. The murmur appeared, disappeared for a time, and finally became permanent. In his opinion suitable employment was of vital importance in treating the disease, and it was even better to take a little risk in recommending employment than to allow the patient time for brooding and introspection.

### OTORRHOEA.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on May 22nd, the President, Dr. F. C. PENNER, in the chair, Dr. J. H. POLLOCK gave an account of 49 cases of otorrhoea observed in Cork Street Fever Hospital.

Dr. Pollock found that from 29 of these a pure culture of *Staphylococcus aureus* was obtained, and from 14 cases diphtheria bacilli were recovered. Treatment by autogenous vaccines resulted in cure or very marked improvement in practically all the staphylococcal cases. He did not think that syringing the ears with antiseptic solutions was beneficial. Very marked anaemia was often present in cases of otorrhoea. Diphtheria frequently occurred in cases of scarlatina and measles, though in these cases the diphtheria

bacilli could rarely be obtained from the throat in the acute stage, but were found during convalescence.

The PRESIDENT said he had noticed that often in cases of severe sore throats, clinically resembling diphtheria, negative results were obtained from a bacteriological examination; diphtheria then developed, and later, when the patient was improving, diphtheria bacilli were recovered.

Dr. J. D. CURTIS said that very often in cases of acute otitis media an obvious cause could be found in the nasopharynx; this cause could be removed, if dealt with rapidly. Dr. W. D. O'KELLY was surprised that none of the cases recorded showed pneumococci, and thought that 29 staphylococcal cases out of 49 was a high percentage. Dr. H. F. MOORE thought the pneumococcus was a very common organism in cases of otorrhoea, and suggested that instillations of ethyl-hydrocupreiu, which killed pneumococci, might be beneficial.

Dr. R. J. ROWLETTE suggested that vaccine treatment should be tried in the more acute cases as in the more chronic cases described. All these cases had been late ones, which would account for the very limited bacterial flora found. Otitis media was generally present in cases of influenza, but these patients seemed to recover without much treatment; he thought it possible that pneumococcal patients also recovered without much treatment. Dr. A. R. PARSONS said that some years ago Sir Robert Woods had found that pneumococci were present in a large number of cases.

Dr. V. M. SYNGE said that in the cases in which diphtheria bacilli had been found, no animal inoculations had been carried out, and therefore it could not be ascertained whether the bacilli were toxin-producing or no. Unless diphtheria bacilli could produce toxin he did not think that they were genuine. He was surprised to hear that Dr. Pollock found the diphtheria bacillus so frequently in the throat in cases of scarlatina and measles; in his own experience diphtheria had been very rarely associated with scarlatina or measles.

Dr. POLLOCK, replying, said that his reasons for postponing treatment until the cases became chronic were that a certain number of these patients recovered spontaneously, and that he wanted to avoid the chance of such recovery after the vaccine treatment had been started.

### Osteomalacia.

Dr. H. F. MOORE and Dr. J. HAYDEN described a case of osteomalacia in an unmarried woman aged 28, in which there was a complete absence of hydrochloric acid in the gastric juice. There was no bending or softening of the bones, though fractures of the pelvis had occurred. The blood calcium was reduced. Dr. Moore discussed the relationship of osteomalacia and rickets, and also referred to tetany. The patient was treated by one drachm doses of dilute hydrochloric acid three times a day. Rapid improvement occurred, and after seven weeks all fractures had healed, while the blood calcium had markedly increased. Dr. GERAGHTY showed x-ray photographs of the bones before and after treatment.

The PRESIDENT said that osteomalacia was a very rare condition: he had seen one case some years previously. Dr. V. M. SYNGE referred to the possibility of lack of vitamin being associated with the condition. It was generally believed at present that rickets was due to absence of the antirachitic vitamin.

At a meeting of the Edinburgh Obstetrical Society held on May 13th, the President, Professor B. P. WATSON, in the chair, a communication was read by Dr. JAMES HENRY on the mobility of the uterus as a factor in the care of the third stage of labour and in the control of post-partum haemorrhage. Dr. Hendry described a simple method by which the mobility of the uterus after the second stage of labour could be taken advantage of. A communication was read by Mr. DAVID LEES on syphilis in pregnancy. The subject was gone into thoroughly, and the contentions of the author were illustrated by descriptive cases. The question of treatment was perhaps the chief import in the paper, and dual therapy was advocated, preferably with a preparation of arsenic and bismuth. No ill effects had been noted in the large number of cases so treated, and bismuth was tolerated well during pregnancy. Mercury could also be given, but not in such large doses, as tolerance was not nearly so good as with the other drugs.

## Reviéws.

### THE RADIO-ACTIVITY OF MINERAL SPRINGS.

FOLLOWING on the discoveries of Becquerel and the Curies in France, and of Rutherford, Ramsay, and Soddy in England, scientists began to study, some twenty years ago, the radio-activity of the mineral springs in several of the European spas. Since then a vast amount of independent physico-chemical, physiological, pharmacological, therapeutic, and clinical research has been carried out. The results have now been collated and examined in an instructive volume<sup>1</sup> by M. PIÉRY, the lecturer on hydrotherapy, and M. MILHAUD, the director of the laboratory of therapeutics, hydrology, and climatology, in the Lyons School of Medicine. It is perhaps the most complete and exhaustive work yet published on the subject, and it is fitting that it should come from the Lyons school, for many of the best known mineral springs of France, such as Vichy, Mont-Dore, Royat, and La Bourboule, are in its immediate vicinity.

The volume consists of a short preface by Professor TEISSIER, an introduction, and four sections. The introduction describes the physical and chemical properties of the radio-active elements and the rarer gases, with a detailed description of the methods of detecting them and estimating their quantity. The unit of radium emanation employed is the millimicrocurie (m.m.c.), adopted by the Congress of Radiology in Brussels in place of the German Mache unit (u.m.), which is equal to 0.4 m.m.c. and therefore readily convertible. The emanations of thorium and actinium derivatives are measured as an electrostatic unit (u.e.s.), equal to 1,000 Mache units. With this essential preliminary information the authors, in the first section of the volume, describe in detail the results of researches into the radio-activity of mineral springs and its geological origin. Several useful tables are given showing the amount of radium emanation (niton) and gaseous products of the principal springs of France and other countries. Stress is laid on the need for estimating the value of radium emanation, not by the number of millimicrocuries in the gases per litre, but by the amount of gases given off hourly. In other words, the horo-radio-activity is the essential measure of emanation value. This is explained by comparing the results in some of the mineral springs. Thus the Boussanges spring, Vichy, has only 0.6 m.m.c. of emanation per litre, but a discharge of about 60,000 litres of gas hourly. The horo-radio-activity is therefore  $60,000 \times 0.6$ , or 36,000 m.m.c. of emanation hourly. On the other hand, the Vauquelin spring at Plombières, with 109,038 m.m.c. of emanation per litre of gas, has only a delivery of 2 litres of gas hourly, so that its horo-radio-activity—218 m.m.c.—is comparatively low. It may be mentioned in this connexion that the Choussy spring at La Bourboule, with 492,420 m.m.c. of radium emanation hourly, is by far the most radio-active of all the French mineral springs. It has not only a high discharge of gas (3,480 litres hourly) but also an exceptionally high quantity of radium emanation (141.5 m.m.c. per litre). In this first section the question of the mineral constituents of the various springs in relation to radio-activity is also considered. Several have small mineral contents or are merely thermal; others are rich in mineral salts and in sulphur, iron, or arsenic constituents. The former are consequently classified by the authors as radio-active springs properly so called, the latter as radio-active mineral waters in which the radio-activity is secondary to the mineral constituents. No tables are given of the estimate of thorium or actinium emanations. Owing to their extremely short life—a matter of seconds—this amount can only be measured satisfactorily at the point of emergence, unless there happens to be a thorium or actinium element in solution or in the sediment.

The next section is devoted to the biological and pharmacological effects of the radio-active bodies, their channels of absorption and elimination, and their action on the

various organs and tissues. The chief difference between the radium and thorium emanation is their action on the blood corpuscles. Radium has little or no influence on these, whereas thorium is said to increase the haemoglobin and diminish the white corpuscles to a marked degree. The third section deals with the therapeutic action of radio-active emanations on individual diseases. Their value in gonitic affections and that of thorium derivatives in diseases of the haemopoietic system stand out as the most determinate effects in hydrotherapy.

The final section contains a description of the installations and methods of radio-active therapy in individual spas of France and other countries, followed by chapters on the indications and contraindications of emanotherapy, as it is called, and on the choice of spas for the treatment of particular classes of disease. Much emphasis is placed on the provision and construction of emanatoriums or installations for the application of radio-active emanation by inhalation. The vault and dome method of construction adopted by the ancient Romans satisfied all the essential requirements. Without knowing why, they hit upon the most practical way of deriving benefit from the emanation in thermal baths. In this connexion the authors consider that the chief value of the immersion baths is due to the emanation given off from the surface of the water and inhaled, and not from absorption by the skin or other channels. Another point is that in places like Vichy and Bagnoles de l'Orne, where there is constant escape of radium emanation into the atmosphere surrounding the springs, patients undergoing the cure are inhaling emanation continuously during their sojourn. Loisel, for example, has stated that the air of Bagnoles is four times richer in radio-active emanation than the air in Paris. The climate, therefore, of the radio-active spas probably plays an important part in the cure, and cannot be transferred to other places in bottles, like the mineral contents of their springs.

The authors have written for the instruction of French balneologists and medical practitioners, but the book is commendably free from propagandism on behalf of the French spas. A chapter, for example, is devoted to the methods and installations in the radio-active bathing establishments of other countries. It includes a description of Bath and Buxton, the only two spas in Great Britain where, they say, radio-activity has been thoroughly studied. But in describing the mud baths they write strongly in favour of the thermal mud baths of France as compared with those of Germany, Czechoslovakia, Italy, and Russia. The French mud baths, of which St. Armand in the north-east and Dax and Barbotan in the south-west are the chief, are naturally radio-active because the springs flow through the mud deposits, whereas in those of other countries the mud is taken from the place of origin at a distance, and often with much delay, and mixed with the water of the springs, and is inert. Further, the French baths are employed at their normal temperature, the others are artificially heated. The former, too, are classed as radio-active properly so called, the latter are sulphur baths or strongly saline; and even those with the highest reputation, such as Battaglia in Italy and Franzensbad in Czechoslovakia, have a less radium emanation than the French mud baths. The conclusion of the argument, therefore, is that France is the country one must go to for a radio-active mud cure. At the same time, the authors acknowledge that the installation of emanatoriums in the French spas is, as a rule, inferior to that in the spas of Central Europe.

Piéry and Milhaud's work merits close study both by balneologists and by all medical practitioners who may be called on to recommend a spa cure to their patients. Hydrotherapy is emerging from its traditional empiricism; but there is still much to be accomplished, not only in perfecting the means and methods of applying the treatment for the cure of the class of patients who have hitherto derived benefit from a sojourn at this or that spa on purely empirical grounds, but also in investigating more closely the conditions under which radio-activity has its origin in each locality and the measure of its quantity.

Further research is needed to detect the presence of thorium, actinium, and other radio-active elements, especially their presence in the sediment and muds of mineral

<sup>1</sup> Les Eaux Minérales Radio-actives. By M. Piéry and M. Milhaud. Preface by M. J. Teissier. Paris: G. Doin, 1924. (Roy. 8vo, Pp. 456; 4 plates (2 coloured), 45 figures, and 25 tables. Fr. 50.)

springs. The dosage and effects of emanation treatment have also to be studied more closely clinically. Much also has to be done in the way of constructing suitable emanatoriums and providing equipment for emanation inhalation.

### CHEMICAL ASPECTS OF IMMUNITY.

THE book by Professor H. GIDEON WELLS, entitled *The Chemical Aspects of Immunity*,<sup>2</sup> has been published as one of the American Chemical Society's series of scientific monographs, and is addressed chiefly to chemists. The technical language of immunology makes difficult reading to all but those who have approached this science by the road of specialized medicine; and the chemist, untrained in pathology, has hitherto received little encouragement in his efforts to master the subject of immunity. Medical science has been the loser thereby, for we must look to the researches of expert chemists for explanations of many of the serological reactions commonly used in diagnosis, and we may hope to learn more accurate quantitative methods from such allies.

Since he is speaking to a non-medical audience Professor Wells begins his book with an introductory chapter in which he defines the technical terms used in immunology, such as antigens, precipitins, agglutinins, toxins and antitoxins, lysins, and anaphylaxis. The ground having been cleared, he proceeds in subsequent chapters to discuss different immunity reactions from the chemical point of view. But this is not a book on chemistry: it is primarily a textbook of immunology, and medical men who have enjoyed the clear descriptions of serological and other technical terms in the introduction need not fear that later on they may find it difficult to follow because a chemist is speaking to chemists. We observe that immunologists are not repaid for their own inhospitality of language, and the author proves that both chemistry and immunity may be clearly dealt with in simple words. One excellent feature of this book is that at the end of each chapter the author has summarized the most important teaching on each theme in the form of a recapitulation, occupying a page or two of print. This enables the reader to pick up the essential points quickly: if read before the text of the chapter the orderly development of the argument becomes more obvious, and if read after the chapter the recapitulation fixes the essential points in one's mind. When touching on subjects which cannot be fully expounded in a book of this size Professor Wells supplies references to guide further study. By a skilful choice of analogies, gathered from wide fields of scientific knowledge, a new significance is often given to familiar facts. Thus, the chapter on immunological specificity is introduced in this inviting fashion:

"We see the manifestations of specificity in so many and so varied processes that many of them are taken for granted, and others are not at first thought of as illustrations of the biological specificity which rules all the processes of life. It must obtain, from the fertilization of the ovum by the specific sort of spermatozoon which alone can enter the germ cell and stimulate division, on through the processes of growth which lead to the formation of specific structures characteristic of the species in form, composition, and function, on to the specific reaction to injury which leads to repair by the proper tissue elements and the specific methods and means of defence against invading enemies. The autumnal reddening of the maple leaf, the yellowing of the birch are as typical examples of chemical specificity as the secretion of a neurotoxic poison by the cobra or the production of antitoxin by a horse immunized with the poison of the diphtheric bacillus. The fact that a dog can follow the trail of his master and recognize him from all others by scent alone, shows that each of us is chemically individual."

Professor Wells's textbook on chemical pathology is known throughout the English-speaking world, and we predict that his monograph on the chemical aspects of immunity will receive an equally wide welcome.

<sup>2</sup> *The Chemical Aspects of Immunity*. By H. Gideon Wells, Ph.D., M.D. American Chemical Society Monograph Series, New York: Chemical Catalog Co., Inc., 1923. (Med. Rev. no. 254; 2 figures, 1 plate.)

### AN INTRODUCTION TO SCHOOL MEDICINE.

Now that *An Introduction to School Medicine*,<sup>3</sup> by Dr. H. LESLIE CRONK, has appeared no doctor engaged in school medical inspection will remain content until such an extremely useful manual has a place on his bookshelf. Information on the minor departures from health of children attending school, their detection, causation, prevention, and importance, is given clearly and concisely, with full references to the authorities quoted.

Hitherto school medicine has been in a somewhat nebulous state, and each individual doctor engaged in the work has perforce had to work out for himself the deductions to be made from his daily experience and observations. The author of this book, who until recently was the assistant school medical officer in the county of Cornwall, has here set down the results of his own experience, with references to similar information collected by others. He states that:

"The school is the link between the intimate sheltered life in the home and the strenuous fight of adult working years; in like measure the functions of the school medical officer lie midway between the personal attentions of the family doctor and the more general and impersonal activities of the medical officer of health."

The book contains a large amount of useful information, and may almost be said to be a complete equipment for a school medical officer.

The first chapters deal with the normal child as regards growth, food, sleep, and teeth; for, in order to recognize slight departures from the normal, the school medical officer must know the normal intimately well. Other chapters are devoted to the recognition of defects in the eyes, teeth, nose, ears, tonsils, and circulatory system. Statistics of various defects are set forth in tables, and the most recent tests are discussed helpfully in the text.

The recognition of tuberculosis in childhood is very carefully and fully dealt with. Deformities are grouped with particular reference to postural deformities, which generally arise during the school period. Very useful information with regard to infectious diseases and the checking of their spread is given. At the end of each chapter is a bibliography and the volume has an index.

The school medical service should be closely linked up with ante-natal and infant welfare care on the one hand and national insurance and factory inspection on the other. All should be co-ordinated to produce the best results in preventive medicine.

### ANNALS OF MEDICAL HISTORY.

THE first number of the seventh volume of the *Annals of Medical History*,<sup>4</sup> which, unlike most journals, has an ever-changing face on its cover, bears on the outside the portrait of Tobias Smollett, whose life is sketched in an interesting manner by Dr. C. K. Drinker of Boston; the well illustrated account of life in Bath, then under the rule of Beau Nash, when Smollett was resident and unsuccessfully sought practice from 1745 to 1762, comes at an appropriate time in connexion with this year's meeting of the British Medical Association. The frontispiece is a reproduction of the print of the portrait of William Cadogan (1711-87) by R. E. Pine in the Royal College of Physicians of London; Cadogan's "Dissertation on the Gout and all Chronic Diseases jointly considered" and a contemporary satire in verso on the author are reproduced with some notes by Dr. John Ruhrh of Baltimore. Dr. Hermann Goodman writes on "Master Dermatologists, based on Diseases named after them," which will serve as a storehouse of information to those interested in eponyms. Dr. Leroy Crammer has done well to provide some further information about early anatomical fugitive sheets as a supplement to his earlier article on the same subject in the fifth volume of the *Annals*; he also writes an appreciative review of Mr. Geoffrey Keynes's *Bibliography of Sir Thomas Browne. The life of James*

<sup>3</sup> *An Introduction to School Medicine*. By H. Leslie Cronk, M.A., M.D., D.P.H. Camb. London: H. K. Lewis and Co., Ltd. 1925. (Cr. 8vo, pp. x + 256; 38 tables. 7s. 6d. net.)

<sup>4</sup> *Annals of Medical History* (Spring Number, 1925). Vol. vii, No. 1. Edited by Francis B. Packard, M.D. Philadelphia, New York: Paul J. Hoeber, Inc.; London: Baillière Tindall and Cox, 1925. (8vo, 122 pp. 10s. illustrated. Subscription in Great Britain £2 2s. per volume of four numbers.)

Menso (1771-1846) of Philadelphia, who was known for his thesis on hydrophobia, which, greatly daring custom, he wrote in English as "being generally useful to my countrymen," is described by Dr. W. S. Miller in an article with a number of illustrations and many annotations. In the interesting article "Su-wen, the Basis of Chinese Medicine," Dr. Percy Dawson utilizes the summary recently given by L. Weiger of this previously untranslated work of unknown authorship, dating from the end of the fourth century B.C. The system revealed in the work is related to the Taoist philosophy. The primordial body, being Su-wen (mystery), is without form or figure and is invisible and impalpable, but enters into the formation of all bodies. The work shows that the Chinese recognized by conjecture, but not by experiment, the circulation of the blood twenty centuries before Harvey's discovery. Among the book reviews which are a feature of the *Annals* attention may be called to the editor's appreciative critiques of Professor M. Bloch's *Les Rois thaumaturges* and Dr. G. C. Peachey's *Memoir of William and John Hunter*; with regard to the wretched story of Home's conduct in dealing with Hunter's manuscripts, Dr. Packman considers that more might have been said, but he explains the length of his review by the good reason that this monograph is "by all odds the best account of both the Hunters which has yet appeared."

### FREUD'S COLLECTED PAPERS.

We have received three volumes of *Collected Papers* by Professor SIGMUND FREUD, and it is proposed to publish a fourth in order that a translation of the whole of the *Sammlung kleiner Schriften zur Neurosenlehre* may be available for English-speaking readers. The papers in this series have been re-grouped, in co-operation with their author, so that they do not follow the same order as in the German original. The date when each paper was written is given, and the editorial preface insists that the only satisfactory way of acquiring a knowledge of Professor Freud's writings is to follow the order of development of his work. Volume I contains the early papers and a lengthy account of the history of the psycho-analytic movement. Volume II includes a number of purely clinical papers, together with some dealing with subjects of general interest; the second section contains all those papers relating directly to the technique of psycho-analysis. Volume III contains psycho-analytic studies of five individual cases.

### NOTES ON BOOKS.

INTO a little book, the *Pharmaceutical Pocket Book*,<sup>6</sup> the Pharmaceutical Society of Great Britain has succeeded in condensing the whole duty of the pharmacist. There is an excellent chapter on the science and art of dispensing, worth reading by the doctor, especially in the matter of incompatibility in prescriptions, which is most delicately dealt with. The dispenser, it is said, must endeavour as far as possible to fathom the intentions of the prescriber; changes are sometimes brought about intentionally; but if the incompatibility is such that the apparent intention will be frustrated, the dispenser should, if possible, communicate with the prescriber. This chapter will be found valuable even by the doctor who does his own dispensing. A list of all the preparations of the *British Pharmacopoeia* is given, the doses are stated in imperial as well as metric proportions, and there is a useful table for the conversion of imperial into metric doses. There are chapters on the analysis of milk, water, and urine; on endocrine organs, food, bacteriology, and poisons. In these matters it might have been wise to lay down the rule that they concern the medical man, are of interest in the complete study of pharmacy, but are not suitable for exploitation as slide-lines in the business of a pharmacist. At the same time a knowledge of poisons and their antidotes may well be of value in an emergency. Of greater importance to the student and practitioner of pharmacy is the chapter on the conditions of sale of poisons in Great Britain, which has been relegated

to small type at the end of the book. The completeness of the little book is shown by its extensive dictionary of synonyms, its table of veterinary posology, and its inclusion of an article on the mysteries of homeopathic dosage and nomenclature.

In *Rejected Addresses* we are told that—

Emmanuel Jennings brought his youngest boy  
Up as a corn-cutter, a safe employ.

That was more than a hundred years ago, and now each successor of red-headed Pat is dignified with the title of "chiropodist." This word has always seemed to us a strange one. Compounded of the Greek words for hand and foot, it means, etymologically speaking, nothing in particular. The logical French, with far more reason, call those who minister to the untoward troubles of the feet "pedicures," and it seems simply that the well intentioned persons who established the Incorporated Society of Chiropodists did not adopt this name for their specialty. Mr. NORMAN C. LAKE, who is the author of *Lectures to Chiropodists*,<sup>7</sup> has been so good as to enlighten and entertain the members of this society and their brethren by instructing them in a number of interesting matters, lying, however, outside the treatment of corns and callouses, and such like. The life and work of Lister, anatomy, pathology, club-foot, pain, galls, varicose veins, and the antiquity of man are only a few of the subjects dealt with. We have no doubt that the students of chiropody were edified, for, as far as it goes, this book forms a useful elementary introduction to various branches of knowledge.

The post-graduate lectures on cancer, delivered under the auspices of the Fellowship of Medicine, have been published in one volume, edited by Mr. HERBERT PATERSON, under the title *Post-Graduate Lectures on Cancer*.<sup>8</sup> The conditions under which such lectures are given lead to emphasis being laid on practical questions such as those with which the practitioner is faced each day, and therefore such a book as this, though it adds nothing fresh to our knowledge of cancer, is likely to be welcomed by many because of its practical character. Eleven lectures are reprinted in this book, the first being by Sir Thomas Horder on "Some medical aspects of cancer," and the second by Dr. Archibald Leitch on "The general pathology of cancer." The remaining nine deal respectively with cancer as it affects some different region of the body—namely, the larynx, oesophagus, breast, stomach, uterus, intestines, kidney, bladder, and rectum, each lecture by an expert in the particular subject. Sir JOHN BLAND-SUTTON observes in a preface written to this book that fortunately these lectures are free from discussions relating to operative methods, and anticipates that their clinical character will make them extremely useful to practitioners.

*Pediatrics for Nurses*<sup>9</sup> is the outgrowth of a series of lectures given by Dr. BALDWIN at the Johns Hopkins School for Nurses during the past six years. It is clearly written and contains twenty-five illustrations and charts; but it is cumbersome and its price would make it in general prohibitive for English nurses. The final chapter on the convalescent child touches on now ground and contains helpful suggestions. In the earlier part of the book the chief interest lies in differences between American methods and those in use in England. Information concerning the normal infant and the premature infant, and the care and feeding of both, is given. Other chapters are devoted to the therapeutics of infancy and childhood, rickets and scurvy, infectious diseases, skin diseases, tuberculosis, syphilis, and the neurotic child. A picture of a cap to prevent ruminant is given. The book should prove useful to doctors who lecture to nurses in this country as a basis of comparison between English and American methods.

We have received a copy, printed in pamphlet form,<sup>10</sup> of the address delivered to a meeting of the North of England Branch of the British Medical Association last October by Dr. WILLIAM ROBINSON, consulting surgeon to the Royal Infirmary, Sunderland. Dr. Robinson's thoughtful address, entitled "On Brains," dealt with the subject mainly from the physiological point of view. His pamphlet is reprinted from the *Northern Counties Medical Journal*.

## INTER-STATE POST-GRADUATE ASSEMBLY OF AMERICA.

## LONDON MEETING.

THE 550 members attending the Inter-State Post-Graduate Assembly of America carried through a heavy instructional and social programme in London before going north on Sunday last. The mornings were devoted to a succession of half-hour lectures, the afternoons to hospital demonstrations, and the evenings to receptions and other functions, culminating in the great banquet in the Guildhall of which some account is given below. On every possible occasion, public and private, the American visitors expressed their warm appreciation of the hospitality, intellectual and social, which had been afforded them, the value of what they had been privileged to see and hear, and the organizing capacity of the executive and officers, in particular their compatriot Mr. Philip Franklin, which had made the meeting possible. Dr. Charles Mayo said repeatedly that nothing would content his colleagues except a return visit of British practitioners *en masse*.

At the end of the series of lectures in Wigmore Hall Dr. Mayo invested a number of representatives of British medicine with honorary membership of the Assembly. These were Sir Humphry Rolleston, Bt., P.R.C.P., Sir John Bland-Sutton, Bt., P.R.C.S., Lord Dawson of Penn, Sir St. Clair Thomson, Sir Arbuthnot Lane, Bt., Mr. W. Girling Ball, and Mr. Philip Franklin. It was announced that Sir Holburt Waring, Sir William Hale-White, Sir John MacAlister, and Sir George Newman, who could not be present, were also to be admitted to the fraternity, and at the Guildhall banquet Mr. Neville Chamberlain, Minister of Health, was made an honorary member.

## SECOND LECTURE SESSION.

Some account of the opening session appeared in our last issue (p. 1051). At the second session, on the morning of June 3rd, six lectures were given, Sir JOHN BLAND-SUTTON presiding.

*Renal Disease.*

The first was by Professor H. MACLEAN, who discussed some aspects of chronic renal disease. He confined himself to ordinary chronic interstitial nephritis characterized by the usual symptoms of retention of nitrogenous waste products and cardio-vascular disturbance. This disease, he said, was progressive and ultimately hopeless, but it was possible by certain tests to form an idea as to the length of time which would elapse before the fatal termination. Within the last ten years very elaborate methods had been introduced in order to ascertain the condition of the renal system, though in Great Britain, on the whole, these had not found much favour. At St. Thomas's, at all events, it was believed that as much information could be gathered from the simpler tests as from the much more elaborate ones. The test most frequently employed was the estimation of blood urea, but the mere fact of a patient showing a high blood urea was no evidence whatever that that patient was suffering from renal disease; if high blood urea indicated renal deficiency, naturally the urine would show a low percentage of urea, and when both the patient's blood urea and the percentage of urea in the urine were high it might be taken as certain that renal disease was not the primary condition. He described a urea concentration test, involving a fifteen-hour abstention from liquid, and thereafter periodic examination of the urine, which was a test, he said, that could be carried out in general practice, and in 90 per cent. of cases would furnish all the information it was possible to obtain. He added that although the textbooks stated that sometimes there were cases of uraemia without albuminuria he did not think it was realized how common this state of affairs was; rather renal changes showed no albuminuria at all.

Sir JOHN BLAND-SUTTON remarked that the impression

which the lecture had left on his mind was that their knowledge of the urinary functions was as unstable as their knowledge of the universe!

*Gastro-jejunal Ulcer.*

Mr. A. J. WALTON, who lectured on gastro-jejunal ulcer, said that in this country a large number of gastro-enterostomies had been performed by men whose experience had been limited to a small amount of war surgery, and no doubt the incidence of complications had been increased as a result of technical errors; but before gastro-enterostomy was replaced by another operation it ought to be remembered that in the hands of the experienced surgeon the operation had a mortality of well under 1 per cent. He had never yet seen a case of true jejunal ulcer; every case had been gastro-jejunal, the ulcer invariably starting at the junction. At one time he believed that gastro-jejunal ulcer was due to the use of a wrong form of suture at the operation, but since the use of silk had been given up gastro-jejunal ulcer had not disappeared, though its incidence had decreased; therefore it could not be put down entirely to the use of non-absorbable suture. Any gross errors of technique certainly did increase the tendency to this complication, but minor variations such as all surgeons practised had no bearing whatever, in his belief, on the incidence. It had been assumed that partial gastrectomy did not carry with it any risk of gastro-jejunal ulcer, and there had been published a large series of cases of partial gastrectomy, generally by surgeons of wide experience, which showed that the mortality of such an operation could be very low. But if the operation was done widely by many surgeons there was no question that the mortality would not be low. The removal of so large an amount of healthy tissue as was involved in partial gastrectomy was an extreme step to take, and he held that this was too severe an operation for the routine treatment of gastric and duodenal ulcers. It should be reserved for those cases in which a gastro-jejunal ulcer had developed.

*The Combating of Venereal Disease.*

Colonel L. W. HARRISON gave an account of the combating of venereal disease in Great Britain by the free treatment of the infected. He mentioned that as long ago as 1899 the British Medical Association proposed at the Brussels Conference on Syphilis a resolution, which was carried, to the effect that all governments should appoint a commission to determine the frequency of venereal disease in the civil population, to inquire as to the facilities for treatment available, and to collect opinions as to the best methods of securing control of venereal disease. Treatment centres in this country numbered 193, of which 142 were in voluntary hospitals, and 51 (in places where it was not possible to obtain such facilities in the hospital) were centres controlled directly by county or county borough councils. The work of the treatment centres was shown by comparing the number of new cases for two recent years:

	1920.	1924.
Syphilis ... ..	42,805	22,010
Gonorrhoea ... ..	40,284	31,272
Soft chancre ... ..	2,442	1,038

At the same time the number of attendances at the centres had gone up, from 1,488,514 in 1920 to 1,645,415 in 1924. It was stated that many persons ceased attendance before treatment was completed, but it was easy to exaggerate that figure. Many of the cases put down as having ceased attendance were those in which the venereal condition had quite cleared up, but the patients were under observation or treatment for some intercurrent condition; others, again, resorted to some fresh clinic and were put down as having given up treatment. The cost of treatment (including laboratory work, supply of arsenobenzol to practitioners, and propaganda) was £380,000 in 1923-24.

*Cancer of the Rectum.*

Mr. W. ERNEST MILES gave a lantern demonstration of the pathology and spread of cancer of the rectum. He said that cancer of the rectum accounted for more than one-third of the cancerous growths which occurred in the alimentary tract. Cancer spread in the rectum in three ways: by the venous system, by direct continuity of tissue, and by the lymphatics. The extent of the circumferential involvement was an indication both of the duration of the disease and of the depth of the local infiltration. The tendency of the spread was upwards, and therefore it was necessary to bring into the area of operation a sufficient upper zone, in particular the pelvic mesocolon, which corresponded in its importance from the point of view of spread of infection to the axilla in cases of breast cancer.

*Auricular Fibrillation in Exophthalmic Goitre.*

Mr. T. P. DUNNILL spoke on the surgical treatment of exophthalmic goitre from the point of view of auricular fibrillation. He began the operative procedure in these cases—the patient having been got by the physician into the best possible condition—by ligating one artery in order to test the reaction to operation, then, after a rest of ten or twelve days, another vessel was ligatured, followed by another long rest, after which one lobe of the thyroid was removed, and later from one-half to two-thirds of the second lobe. The cases were put on quinidine, but quinidine could not get them regular while the thyroid toxin was still working on their heart muscle. Quinidine was able to act on the heart muscle to restore it to regularity, but there was a toxin in the thyroid which was able to interfere with the neuro-muscular heart mechanism and make it fibrillate, and so long as that continued quinidine was of no permanent avail. The chief danger was in operating on the wrong type of case. Of 26 patients he had operated on, 3 had died, and 2 others had had only one lobe removed, and still fibrillated on exertion; the remaining 21 had never fibrillated from the time the operation was completed, and the records went back to 1919. The treatment was lengthy—each case would take from six to nine months for the medical and surgical procedures.

*The Heart in Influenza.*

The concluding lecture was given by Dr. STRICKLAND GOODALL, whose subject was "The heart in influenza." He said that a critical survey and analysis of the history of large numbers of heart cases which he had had the opportunity of examining carefully during the past twenty years had convinced him that the etiology of heart disease in this country was changing. Up to a few years ago the only antecedent disease to which any attention was paid in connexion with heart trouble was rheumatism, and if it was found that the patient had suffered from no rheumatic manifestations very little heed was paid to any other complaint from which he might have suffered. Within the last few years one had been struck by the fact that there were a very large number of cases in which definite heart involvement occurred with an antecedent history of influenza. He showed electrocardiograms of cases every one of which had been the subject of the most critical examination for rheumatic history, and no such history had been elicited. These were cases of acute paroxysmal tachycardia of the ventricular region, or auricular fibrillation or flutter, all following upon mild influenza. It was not true that influenza gave rise to a poison which caused many different diseases; all these conditions represented injuries to the myocardium, which was poisoned, with consequent impairment of function. The influenza virus was a muscle poison which might attack any part of the heart. If it attacked the auricle it gave rise to auricular fibrillation or flutter; if it attacked the bundle of His it gave rise to heart-block, temporary or permanent; and if it attacked the ventricles it gave rise either to extra-systoles or to ventricular fibrillation. The myocardial condition following on influenza might develop from seven to twelve days after everything seemed well, the gastro-intestinal disturbance having cleared up, and the doctor having ceased his visits.

## THIRD LECTURE SESSION.

*Medical Research in Great Britain.*

The third lecture session, on the morning of June 4th, was held under the presidency of Sir STCLAIR THOMSON. A sketch of medical research in Great Britain was given by Sir WALTER FLETCHER. He claimed that in this country there had never been wanting men of first-rate ability in science, but research had been crippled by want of means, and that discredit was most marked when the country was most rich. The great achievements of scientific men had been largely dependent upon the accident of financial ability. What would Sir Isaac Newton have done without the monastic endowments which came to Trinity College, Cambridge? It was the endowments of the Royal Institution which supported Faraday in his great work and made Albemarle Street the cradle of the electrical industry of the world. Darwin was able to do his work because he was a rich man, and the same was true of Lord Rayleigh. Very few British statesmen had appreciated the national and world value of helping on the new knowledge. He could name only four conspicuous princes or statesmen in England who had made a mark in this particular. These were: Henry VIII, who endowed colleges under the advice of Thomas Linacre, founder of the Royal College of Physicians; Charles II, who founded the Royal Society; Albert, Prince Consort, who took an active part in the promotion of scientific institutions and research in the middle of the last century; and Mr. Lloyd George, to whom three remarkable departures were due—the foundation of the Development Commission, which had to do with the development of roads and agriculture, the foundation of the Medical Research Council, and, modelled on the Council, the foundation of the Department of Scientific and Industrial Research. The lecturer described the functions of the Medical Research Council, which at first had £40,000 a year to spend, and now, in spite of the impoverishment caused by the war, had £140,000. That annual appropriation had been of immense value. He told the story of the beginnings of the work at Cambridge by Hopkins and others on nutritional problems, and also other episodes of recent research. The State recognition of research had served to stimulate voluntary endowments, and here he mentioned the generous benefactions of the Rockefeller Foundation, which since the war had expended two million sterling in Great Britain, besides one and a half million sterling in other parts of the British Empire.

*Symptoms of Suprarenal Disease.*

Dr. GORDON HOLMES addressed the Assembly on certain symptoms of suprarenal disease. He described two cases which chance had brought in his way which threw some light on the functions of the cortex of the suprarenal body. Hitherto very little had been known of the effects of pathological lesions affecting the cortex. One of these cases, in a girl, exhibited signs of sexual inversion; after a period of normal development, with commencing menstruation, the menses ceased, and she began to show male characteristics, both physical and mental. Ultimately a large tumour was discovered projecting under the liver. On removal one-third of the tumour tissue was found to be identical with the cortex of the normal suprarenal body. Thirty-six days after the tumour was removed she recommenced menstruation, in three weeks an abnormal growth of hair began to fall away, and in three months no trace of abnormal hair remained on face or trunk, her figure began to develop the female shape, and she was now a normal young woman. The other case was that of a girl, very obese and mentally dull. Pituitary disease was suspected, but the type of obesity was not that which was found in such a condition. Ultimately this girl died of bronchopneumonia, and at the autopsy striking changes were found in the suprarenals, almost all the cells of which were abnormal.

*Operation in Gastric and Duodenal Ulcer.*

Mr. JAMES SHERREN dealt with the considerations that should guide the decision as to operation and the choice of operation in chronic gastric and duodenal ulcer. The more one saw of chronic duodenal ulcer the more one realized that it was a condition associated with a great amount of

risk. In the hands of a surgeon used to abdominal work operation was the safest form of treatment. New operative procedures were constantly being brought forward, but duodenectomies and wide partial gastrectomies were no guarantee against recurrence of the ulcer. He believed that gastro-jejunostomy, efficiently carried out, would bring about the healing of all duodenal ulcers, except those very large ulcers which eroded the pancreas, and sometimes even those would respond. The problem was to prevent secondary ulceration, and all efforts should be directed to that end. To bring about healing the gastro-jejunostomy must be efficient, it must be posterior, vertical, and extending from the lesser to the greater curvature. In uncomplicated cases he thought the duodenal ulcer should be left alone. He only dealt directly with the ulcer when it had been causing recent haemorrhage. With regard to chronic gastric ulcer, the danger of the development of carcinoma had to be reckoned with. There was no doubt that malignant disease did develop on simple gastric ulcer. Small mobile ulcers were quite well treated by gastro-jejunostomy. Large indurated ulcers eroding the pancreas and liver should be treated by partial gastrectomy. He urged as far as possible conservative treatment of lesions, believing that any additional cures which might occasionally be obtained by more radical procedures were more than set off by the increased risk.

#### *Cancer of the Larynx.*

Sir STCLAIR THOMSON, after some remarks on cancer in general, from which, he said, 50,000 people in this country died last year, spoke on cancer of the larynx. Intrinsic cancer had yielded in his hands 80 per cent. of lasting cures—by "lasting" he meant anything up to fifteen years' survival. He described by means of successive lantern illustrations his technique in the practice of laryngo-fissure. He deprecated laryngectomy when laryngo-fissure was shown to be not very complicated, but certainly safe, and affording lasting results. Complete laryngectomy was much more successful nowadays than formerly, in respect of operative mortality and ultimate results, for the good reason that it had been almost entirely abandoned for extrinsic cancer. He had done laryngo-fissure some sixty-six times. He gave no opiate of any kind before or after operation, because he had found that this led to a certain amount of operative mortality. As illustrating the sex incidence, sixty of the sixty-six cases were in men. In intrinsic cancer of the larynx it ought to be generally recognized that hoarseness was the first symptom. Persistent hoarseness for more than three weeks should lead to the case being examined by an expert. Sir Felix Semon used to regard fixation of the cord as the characteristic, common, and early symptom. It was certainly characteristic, but it occurred late, and unfortunately many cases escaped treatment because, it was said, the cord was mobile. But to wait until the cord became immobile meant a deeper infiltration. Sir StClair Thomson showed five patients on whom laryngo-fissure had been done. All of these were cases of cancer which had been confirmed by the microscope, and in all of them the patients appeared well, and were able to speak with more or less ease.

#### *Functional Nervous Disturbance in Children.*

Dr. H. C. CAMERON took the audience away from the operating theatre and the laboratory to what he called "the growing point of all neuropathy" in the forcing-house of the nursery. It was only the physician, he said, who was able to detect the very first deflections caused by psychopathic processes, and from all the tangle of forces acting on the child in the home to isolate that which was responsible for any particular disturbance. There was a certain resemblance between the abnormal conduct of an unstable child and of persons who had come to be definitely regarded as insane, between the symptoms which resulted from the functional weakness of the immature brain and those which resulted from degeneration and disease; in ascent and descent the same country was traversed. One of the commonest results of excessive mothering was the production of what he called—to borrow a word from the vocabulary of the alienist—negativism. The negativistic child was the one who, if it were proposed to him that a movement be made downstairs, would immediately rush to

the top of the house. Negativism was the response to a fault of parental management indicated by a constant and repeated attempt to secure control and a constant failure to achieve. One of the commonest things about which doctors were consulted was want of appetite—often a veritable anorexia nervosa. Among poor children this fault was hardly ever met with, for obvious reasons, but in well-to-do households the child who persistently refused food was quite familiar, and usually the food that was refused was the nutritional milk and so forth which the parent particularly wanted him to take. The way to combat this refusal to take food was completely to alter the suggestion with which the food was brought. The mother should give the appearance of haggling over the food she wanted the youngster to take, the second helping should be conceded with a proper amount of reluctance, and this camouflage might induce a willingness to take what had absolutely been refused before. It was easy to see the part that negativism played in pseudo-constipation; in some cases of negativistic resistance the child had actually to be given a state of diarrhoea or even incontinence before the resistance could be overcome. Another group of common nervous disturbances in children were ingrained and perpetuated by the ill judged efforts of the parents to stop them. It would be better to correct the habit of infantile thumb-sucking by ordering the child in the most peremptory fashion to suck his thumb three times a day. In infantile masturbation the awful anxiety of the mother often served only to fix the habit in the child. If splinters were used to prevent masturbation it was worth while to take any amount of trouble to convince the child that the apparatus was used for some other purpose, otherwise the child's attention was riveted on the fault. Purposeless crying, again, was due to the emotional reaction produced in the mother by the cry. In the nursery there was scope for an elementary sort of psycho-therapeutics, and the task of the medical man was to see that the tremendous force of maternal attraction was used for good, and not, as often happened, for ill.

#### *The Speed of Life and Disease.*

The final address was given by Lord DAWSON OF PENN, who spoke on "The speed of life and disease." He remarked, as Sir Thomas Horder had done two days previously, on the change which had taken place in the character of disease. In the West, at all events, pestilences had ceased to devastate the peoples, though it was true that cancer remained, baffling and destructive. A time might be anticipated when specific diseases would be relatively small factors in the general mass of ill health, and their place would be taken by subinfections which caused slow deterioration instead of quick destruction. Many of the causes of the subinfections lay within them—for instance, the streptococcus and the colon bacillus. The microbes of acute infections invaded the human organism in force and laid it low—they were a visitation, and on recovery of the patient they disappeared; but the microbes of the subinfections, like the poor, were always with them, they shared the active life of their host, troubling him little when he was fit, taking advantage of his indispositions. Against these subinfections the measures of public health were of small avail. Here the last word was with the individual. The thoughts of the medical man went first to the treatment of the foci. It was true that where these foci could be treated all authorities would agree that they should be, though in medicine there was no such word as "always," and it might sometimes be better to leave the focus *in situ*. It was necessary to approach these subinfections with more judgement than had hitherto been applied to them, and assess the part they played and the advantage and difficulty of their removal in each case. The effects of subinfection depended on the vitality of the individual and on the conditions of his life. A measure of struggle promoted health, but when the struggle was severe and continuous, as it was in modern life, the result was to produce not strength but stress. Material progress, especially in all that concerned movement, had been so rapid that it had outstripped man's rate of adaptation. Men were so tuned up that they carried over the tension from their work to their play, and the result was fixity, not flexibility. Much might be done by a more careful selection of careers and

employments—not by an official system of card-indexing, but by a careful study by the medical man of each individual case. Everyone was familiar with the man of sound physique, strong digestion, good staying power, with an impressionable nervous system, sensitive, ambitious, whose attitude to modern life was one of tension, who had lost his capacity for relaxation, who could never let go. That man, in spite of vaso-constriction and rising blood pressure, was unaware of any untoward happening, and went on apparently just as efficiently as before. His very constitution became his own undoing. If he had a mild illness it might be the saving of him. But he went on until at last, with little or no warning, cerebral haemorrhage, cardiac insufficiency, or some infection not serious in itself but serious to him, brought about his end; he died of his qualities. In another man of a somewhat different type the effect of strain showed itself in disordered movement and disordered secretion of the gastro-intestinal tract. Often such a man was said to be suffering from colitis—a blessed word—but the nearer one came to the beginnings of disease the more difficult it was to bring the description within a definition. The remedies belonged largely to that side of medicine which was known as education. The tense and hypersensitive people must be taught how to maintain relaxation: the country retreat, the Sunday ramble, the quiet game, the rhythmic exercise, the cult of the garden, the browse in the library, the evening with music, the periodical getting back to nature or to the cloister. Man still needs the “desert place apart” and what it implies.

#### THE GUILDHALL BANQUET.

The ancient Guildhall, lent by the Corporation of the City of London, gave a mellow setting to the great banquet which was the last official event of the Assembly in the capital. On this occasion the visitors, after being guests all the week, became the hosts, and hosts in what they as well as those they entertained might regard as one of their ancestral halls. Gog and Magog overlooked a company of seven hundred seated at the tables, and only by the use of microphones and amplifiers could the speeches be heard in every part of the hall. There was a hint of mediæval ceremonial in the white-capped chef on his high platform carrying the baron of beef, and the turtle soup was ladled out lovingly in the manner dear to the City Fathers. A rumour had been circulated that the banquet was to be “dry,” but presumably it was held to be unthinkable that the Eighteenth Amendment should extend to the Lord Mayor’s banqueting chamber, and the proceedings were, in Sir StClair Thomson’s phrase, “not wet, but pleasantly moist.”

Dr. CHARLES H. MAYO, who presided, had the Right Hon. Neville Chamberlain (Minister of Health) and Mrs. Chamberlain on his right and left hand, and others at the principal table were:

Mr. Ray Atherton (First Secretary, U.S. Embassy), Sir James and Lady Berry, Vice-Admiral and Mrs. Joseph Chambers, Lord and Lady Dawson of Penn, Sir Alfred and Lady Fripp, Sir Kenneth and Lady Goadby, Sir Thomas Horder, Dean Inge, Viscount Knutsford, Sir William and Lady Arbuthnot Lane, Major-General Sir William and Lady Leishman, Dr. and Mrs. Franklin Martin, the Right Hon. T. P. O’Connor, M.P., Sir Cooper Perry, Sir D’Arcy Power, Sir Humphry Rolleston, Sir Arthur Stanley, Sir Harold Stiles, Sir StClair Thomson, Sir Charles and Lady Wakefield, Sir Culbert and Lady Wallace, Sir Holburt and Lady Waring, Mr. Henry Wellcome, Sir W. de Courey Wheeler, Sir William and Lady Hale-White.

A telegram was read from the King, in answer to a congratulatory message from the members of the Assembly. His Majesty replied, thanking them for their good wishes and expressing the hope that their stay in this country might be both interesting and agreeable. A message was also read from the Hon. Frank B. Kellogg, Secretary of State at Washington, expressing his deep interest in the meeting, recognizing as he did “the incalculable benefits which have accrued to the human race through the scientific study and treatment of disease, and the still greater advancement which may be made in medical science through the interchange of views of experienced practitioners.” The toasts of “The King” and “The President” were drunk, and to the latter “The Star-spangled Banner” was sung with great fervour.

Mr. NEVILLE CHAMBERLAIN, in proposing the toast of “The Assembly,” said that it seemed to him that this adventure or expedition of the members might mark something like an epoch in medical history. There had been other visits of professional men from one country to another, either to increase their knowledge or to spy out the nakedness of the land, but he doubted whether there had ever been an instance of a great body of men leaving their practices for so long a time and crossing the ocean in order to acquaint themselves with the progress of medicine in another land. In these days one discovery of medicine succeeded another with startling rapidity. So many scourges had been brought under control that there would be little left for practitioners to do were it not for the fact that new diseases were discovered at a rate approximately equal to that at which the old diseases were eradicated. The general practitioner had special opportunities for educating the public. The community had awakened, perhaps rather late in the day, to the special dangers which attended the crowding together of great masses of people in large cities, and an elaborate organization of sanitation and inspection had been built up. But it was necessary to enlighten the people as well as to improve their environment, and while he would be the last to undervalue the health propaganda carried on by public authorities he could not help feeling that the most powerful and efficient propaganda must always be that which was directed by the general practitioner. Mr. Chamberlain added that, of course, medicine must be international, and he thought it would become more and more so as the years went on. But it was easiest for those who spoke a common language to exchange ideas, and in that respect he felt that there was a great opportunity before the profession of the English-speaking nations. With the natural advantages they possessed they could lead the world in the great war against disease. Therefore this visit would be treasured by those in England because they saw in it the promise of an even more fruitful and abundant co-operation.

Dr. MAYO said in response that their English kinsfolk did not realize how much had been accomplished by this wonderful reception. One of the most important ideas which the visitors would take back with them was that there existed in Great Britain a Minister of Health. In America they had not got so far, nor, indeed, had they a Minister of Education. The creation of the Ministry of Health was due to the combined effort of the medical profession. In every community the condition of health had advanced just as far as the medical profession was capable of carrying it. He went on to speak of the desirability of having in London a great central post-graduate school, where men from all parts of the world could come and sit at the feet of the leaders of British medicine. As instancing the appetite for instruction among those who had come across with him on this occasion, he mentioned that on the boat they had had no fewer than sixty-five lectures and addresses!

Dr. HUGH CANOR (Professor of Surgery, University of Michigan) proposed the health of the British medical profession. He spoke of the influences upon American medicine, especially on the Atlantic side. American clinicians of the seventies and early eighties were much impressed by the French school. Afterwards came the striking and profound influence of the German school, with its accent on the science as contrasted with the art of medicine. This influenced greatly the trend of medical education in the States. It had led, perhaps, to a tendency to lose sight of the patient in considering the pathological process. They had come now to the turning-point, when the question was whether clinical medicine could hold its own, and it was of great interest and importance that at this juncture they should have come to London, where the greatest clinical school in the world had been built up.

Dr. WOODS HUTCHINSON (ex-President of the American Academy of Medicine), who also spoke to the toast, commented on the change which had taken place in therapeutics. Nowadays he was the best physician who knew the worthlessness of most drugs, and extolled only the six or seven real remedies in materia medica. Formerly it was the fashion for the doctor to prohibit many articles of

food, chiefly those which the patient most fancied, but nowadays these foods had all come back into medical favour on account of the vitamins they contained, or, if they did not contain vitamins, one could be nearly certain that they contained iodine, which was good for the thyroid gland. Dr. Hutchinson was hardly in accord with what had been said about the overworked business man, and the need in later middle life for taking things quietly. When a man got to 60 he could afford to do a little experimentation. The speaker was not in favour of slowing down when a man had done the best part of his work and was waiting for his discharge. On the contrary, the happiest thing to do was to put on full steam, to be adventurous, to take risks, to live to the full, until the lenticular striated artery snapped at the base of the brain. The speaker gave some account of public health on the other side of the Atlantic, and mentioned that Mr. Ford in the salvage department of his factory employed 1,100 consumptives, each of whom earned from six to nine dollars a day, and the Ford works were the most successful sanatorium he knew of anywhere in the world.

LORD DAWSON OF PENN, in a brief response to the toast, spoke of the widening horizons of medicine, the proud inheritance of the English-speaking nations, and the limitless possibilities of achievement in co-operation. The enthusiasm and energy of the visitors had been a continual surprise and delight, and he believed that those who had come seeking knowledge from across the seas had brought to their hosts more than their hosts had been able to give them in return.

SIR W. ARBUTHNOT LANE, in proposing the toast of "The English-speaking Nations," spoke of the hope they had in London of establishing a great teaching centre to which their friends from America and the Dominions would continually come. Sir STCLAIR THOMSON also spoke to the toast in a speech which showed that even twice-told stories can be very delightful. He declared that there was nothing to separate the two greatest English-speaking nations, except ignorance and water. The devotion of the Americans to Shakespeare had struck him—a devotion not always manifest among the people in Shakespeare's own country. Indeed, the desire on the part of many to bring in a visit to Stratford-on-Avon was the only thing which had threatened to disarrange seriously the Assembly programme.

Dr. FRANKLIN H. MARTIN (Director, American College of Surgeons), in his response to the toast, implored the leaders of medicine in this country to set up a system of post-graduate medicine worthy of the capital of Anglo-Saxondom. All that it required was organization. There were facilities in London for teaching medicine and surgery which were second to none. Providence long ages ago refused to allow the Thames and the Seine to flow into the Rhine. Why not see to it that scientific medicine no longer flowed into the Rhine? Clinical facilities in London were largely going to waste. There were wonderful medical schools in London for teaching students about to enter medicine, but the resources that might make London the centre of post-graduate teaching were not being used. It was a humiliation to those of them from the West to have to pass through New York and through London to Berlin and Vienna to receive teaching in a language they did not understand. Was it not possible to have in London a great centre for the post-graduate teaching of medicine?

#### THE PILGRIMS' DINNER.

Nothing could be more "fraternal" than the Pilgrims' entertainment of the Inter-State Post-Graduate Assembly of America, at the Hotel Victoria, Northumberland Avenue, on June 4th. The DUKE OF CONNAUGHT, the President, welcomed the guests. He recalled the saying that medicine had now become international, so that the guests were there for an international purpose, and he was certain that they would all feel at home in this country. The Foreign-Sent Guy, Mr. AUSTEN CHAMBERLAIN, made an amusing attempt at proposing the health of the American delegation of what appeared to him to open so wide a vocabulary of the such extensive knowledge that no one child was the one of the *Encyclopaedia Britannica* or the *British Medical Journal* could be competent

to propose it. Mr. Chamberlain said he had not yet recovered from his wonder that, except in Russia and on its boundaries, the great war had not been followed by plague. No comparable event in the history of the world had left so little trace on the health of communities. It was due to the knowledge which doctors had spread throughout the world. Mr. Chamberlain related a story, told by his father, of someone who did not agree that the climate of India was unhealthy, since, except for measles, smallpox, and three attacks of swamp fever, he had never had a day's sickness in his life! Dr. CHARLES MAYO, in reply to the toast, emphasized the unity of medicine. He felt that more good would develop from the present "invasion" of England by America than, perhaps, from that of any other group that had visited this country. The guests were leading men in their profession wherever they came from: a large proportion were in contact with the people as general practitioners, and on their return home they would disseminate the knowledge they had obtained from the "old home." The great men of England belonged to them because they were themselves from England; they had the same ideas and were of the same stock. On previous occasions the visitors had been mainly specialists. Specialists were a peculiar people whom he would call accumulators. The men who were present, as general practitioners, were distributors; and they had been brought into contact with all that was best in the greatest city in the world. At the end of his speech Dr. Mayo made the Duke of Connaught, Mr. Austen Chamberlain, and Lord Desborough honorary members of the Inter-State Post-Graduate Assembly of America. Sir JOHN BLAND-SUTTON proposed the health of the Chairman, and the DUKE OF CONNAUGHT replied.

#### COMPLIMENTARY DINNER TO DR. MAYO.

On the day before the visitors left London for the provinces a complimentary dinner was given to Dr. Charles H. Mayo by the Surgical Section of the Royal Society of Medicine. This took place at the Hotel Cecil, with Mr. HERBERT PATERSON, President of the Section, in the chair. Among others present were Dr. Franklin Martin, Sir StClair Thomson, Mr. J. C. C. Davidson, M.P., the Right Hon. T. P. O'Connor, Sir W. Arbuthnot Lane, Sir Anthony Bowlby, Sir William Macpherson, Sir D'Arcy Power, Sir George Blacker, Dr. H. Cahot, Dr. Woods Hutchinson, Sir James Berry, Mr. H. S. Sonttar, and Mr. Swinford Edwards. Many of those present were accompanied by their ladies. Mr. PATERSON, in proposing the health of the guest, remarked that Dr. Mayo was the son of an Englishman, as his father was born at Eccles, near Manchester. The success of the Mayo Clinic was due to the combination of the highest professional skill, the consideration of the best interests of the patient, and the most highly organized business methods. He praised alike the versatility and the modest disposition of the guest, and spoke of the value of clinical congresses in cementing the bonds of friendship and good fellowship between the English-speaking peoples. These friendly invasions had become established, and he hoped they would be long continued. Dr. MAYO, in his reply, paid a tribute to his brother, Dr. William James Mayo, and expressed his sense of the compliment paid him by the Surgical Section. Mr. J. C. C. DAVIDSON, M.P., Parliamentary and Financial Secretary to the Admiralty, proposed the toast of "America and American Surgery," to which Dr. FRANKLIN MARTIN replied, and the President of the Royal Society of Medicine (Sir StClair Thomson) and the Chairman had their healths proposed respectively by Sir WILLIAM ARBUTHNOT LANE and Sir JAMES BERRY.

#### OTHER FUNCTIONS.

Following upon the morning lectures, the visitors made their way, by a fleet of special motor buses, to the various hospitals where demonstrations of special cases, operations, and lectures by members of the staff formed the usual programme. Garden parties were arranged at the London, St. Thomas's, and St. Bartholomew's Hospitals. The medical staff of the Central London Throat, Nose, and Ear Hospital entertained a party of forty to luncheon at the Carlton Hotel before the hospital was visited.

The evening receptions included one at Lansdowne House, where the guests were received by Mr. H. Gordon Selfridge and Princess Wiasemsky; another by H.E. the American Ambassador, at Crewe House; and a third at the house of the Royal Society of Medicine, when Sir St. Clair Thomson, President of the Society, with the other officers, received the guests, whose numbers were such as to tax the full resources of No. 1, Wimpole Street, great as they are. It was one of the most brilliant of the series of receptions that the Royal Society of Medicine has organized.

A reception at the Royal College of Surgeons was given in the afternoon, when Sir John Bland-Sutton, the President, gave a short lecture on "The psychology of animals swallowed alive." He showed that the story of Jonah does not stand alone even in human history, while among reptiles and deep-sea fishes swallowing alive appeared to be the order of the day. He exhibited from the College museum some creatures which had been swallowed alive by animals whose digestion was not over-dainty. Some fishes, he said, had stomachs so distensible as to enable them to

swallow larger fish than themselves, though the victim sometimes wreaked a fearful *post-mortem* vengeance.

Among other events of the week were receptions by Viscountess Bryce, for the English-speaking Union; by Professor G. M. Gayley, for the American University Union; and by the American Women's Club. The visitors were entertained to lunch by the English-speaking Union, when Sir W. Arbuthnot Lane was in the chair, and by the American Society in London, under the chairmanship of Mr. Wilson Cross. On the invitation of Messrs. Parke, Davis and Co. a party of eighty visited Windsor by motor car and had lunch at the company's laboratories at Hounslow. A party of nearly 300 was received at the Houses of Parliament by Sir Harry Brittain, M.P.

The arrangements for the whole meeting were in the hands of an executive committee under the chairmanship of Sir Humphry Rolleston, and there were a Medical Programme Committee, a Hospitality Committee, and a Ladies' Committee, under the chairmanship of Sir Holburt Waring, Mr. F. E. Powell, and Lady Waring respectively.

## The British Medical Association's Scottish House.

### OPENING CEREMONY.

THE Scottish House of the British Medical Association, which has recently been acquired at 6, Drumsheugh Gardens, Edinburgh,\* was on June 4th formally opened by the Right Hon. Sir John Gilmour, M.P., Secretary for Scotland. The ceremony took the form of a luncheon, given by the Scottish Committee of the British Medical Association, which was largely attended by representatives of the medical profession and various bodies connected with it in Edinburgh. Dr. C. E. DOUGLAS, Chairman of the Scottish Committee, presided.

Among those present were the Lord Provost of Edinburgh, Sir William L. Sleight; Lord Mackenzie, Chairman of the Hospital Services Committee; Dr. R. A. Bolam, Chairman of Council, Dr. H. B. Brackenbury, Chairman of the Representative Body, Mr. N. Bishop Harman, Treasurer, Dr. Alfred Cox, Medical Secretary, and Dr. J. R. Drever, Scottish Medical Secretary, of the British Medical Association; Professor G. Lovell Gulland, President of the Royal College of Physicians, Edinburgh; Professor T. K. Monro, President, Royal Faculty of Physicians and Surgeons, Glasgow; Sir David Wallace, President, Edinburgh Medico-Chirurgical Society; Professor G. M. Robertson, President, Medico-Psychological Association; Dr. A. K. Chalmers, President, Society of Medical Officers of Health; Dr. Drummond Shiels, M.P., President, Royal Medical Society, Edinburgh; and Sir Robert Philip.

#### Speech by the Secretary for Scotland.

SIR JOHN GILMOUR, in declaring the House open, said that those who represented the British Medical Association had applied their minds and energies to bringing healing and light into the community. The Association not only included the country in which they stood but the whole United Kingdom, and the power and influence of the Association was becoming Empire-wide. He was sure he was speaking for His Majesty's Government when he said that they realized very fully indeed the importance of bringing together all well considered opinion upon the increasingly difficult problems with which they were confronted to-day. The British Medical Association had not only banded its members into a great organization, but it had done more in producing a journal which was of great value as a record of medical thought and research. The *British Medical Journal* was a source of great value in post-graduate work to many men who, having become efficient medical practitioners, disappeared into the corners

of the earth. They had met that day for a fresh departure in the history of the British Medical Association. He believed that the relationship of their Association and other medical bodies to Government departments, such as the Board of Health for Scotland, had been essentially of a useful nature, and if in any measure during his present tenure of office he could increase the work between them he would feel rewarded. The health and the housing of the people were clamant and difficult problems, which could only be solved if there was a recognition both by Government departments and by medical associations that they must work together for the solution of these difficulties.

Dr. R. A. BOLAM, replying, said that it was a source of satisfaction that the imperial bearing of the Association was recognized in high quarters. He said that in the Council of the Association, over which he presided, there was a corner called the Scottish corner, which sometimes emphasized the truth of the maxim that you could sit on the rose, you could sit on the shamrock, but you could not sit on the thistle. Nevertheless, they always looked to the Scottish corner for sound guidance. He continued that the outlook for the British Medical Association was good, and they hoped within a month to open their new House in London. He had on occasion resented the comment that the Association was a trade union, for he felt that in it there was something infinitely stronger and greater than a trade union, and he believed that their influence with Government departments was now deservedly great, and was an influence for the good of the country. Dr. Bolam then handed over the custody of the House to the keeping of the Scottish Committee.

The CHAIRMAN, in thanking Dr. Bolam and accepting the custody of the House, remarked that during the last five years the Association's membership had increased by nearly 80 per cent. In the course of an admirable speech, Dr. Douglas drew an analogy between the medical profession and the Army. Every man in each of these callings was, he said, in the first place a keen individualist, depending upon his own strength and brain; but just as the soldier would be ineffective without the organization of the Army, so the doctor nowadays would be able to achieve little without the British Medical Association. There were some respects in which it was necessary for the Association to act as a trade union, but he could say without fear of contradiction that nothing that the Association had ever done had been contrary to the public interest.

The toast of "The City of Edinburgh" was proposed by Dr. R. C. BUIST, Dundee, and acknowledged by the Lord Provost, Sir WILLIAM SLEIGHT; the toast "Floreat Res Medica" was given by Sir ROBERT PHILIP; and that of "The Chairman" was proposed by Dr. H. B. BRACKENBURY.

## British Medical Journal.

SATURDAY, JUNE 13TH, 1925.

### FAR FROM THEIR ENEMIES AND THEIR FRIENDS.

THE medical report of the Cassel Hospital for Functional Nervous Disorders, a summary of which is given at page 1102, merits close attention at the present time, when so much thought and labour is being expended on the types of provision needed for the adequate treatment of the various forms which mental disorder assumes. That there is a serious need for hospitals taking types of case similar to those for which the Cassel Hospital is intended there can be little doubt. The complex and artificial conditions of modern life would seem to be responsible for an increasing tendency to "neurasthenia." The widespread interest in psychotherapy and the growing volume of literature on the subject are indicative of the fact that there really is a social problem requiring solution. Fortunately a cessation from work and isolation from social life are unnecessary measures in many cases of nervous illness; such measures, indeed, are often undesirable, and it is an essential part of the treatment that the patient should remain in active contact with life. There are cases, however, for whom sanatorium treatment is a necessity, and there is little question that by such treatment many patients can be saved from a life of chronic invalidism which renders them not only unproductive themselves, but liable to deplete the energies of those with whom they live; for it has to be recognized that mental illness in any form is more exhausting to the entourage of the patient than any other type of illness.

Fortunately there are now many more facilities for the treatment of the milder forms of mental disorder in persons of the professional and business classes than was formerly the case. The voluntary boarder system has been a great benefit to a certain type of patient, and, as is evident from the report of Dr. T. A. Ross, the medical director, the Cassel Hospital is meeting the needs of patients for whom a mental hospital would be unsuitable. We would emphasize the fact, however, that there is absolutely no provision for the sanatorium treatment within the means of persons belonging to the artisan class who are the subjects of functional nervous illness. Every practitioner has brought home to him the fact that artisans, especially those of the intellectual and ambitious type, are liable to break down with nervous illness, after having struggled to acquire a position of moderate comfort. Very often the collapse occurs at the time when the patient is placed in a position of responsibility which it has been a life's ambition to achieve, and he develops a condition which renders him quite incapable of effective and productive action. In such cases the practitioner is helpless because the sanatoriums to which the patients should be sent, and where, as the Cassel Hospital report shows, they may be greatly benefited, do not exist. In such cases we discover a strong argument for the development of psychiatric clinics. The necessity for provision of this kind is, of course, generally recognized, and Professor Pierre Janet has recently made some interesting com-

ments and suggestions on the subject. He refers to the need of organizing treatment for curable neuro-paths whom it is necessary "to transport far from the noise of the city, the turmoil of business, far from tramways and telephones," and, incidentally, far from their families, their enemies, and their friends. He points out that convents formerly furnished such patients with the retreats they needed, and that while these institutions must have engendered some cases of insanity, they prevented and cured many others that would have developed in a life in the outside world. He suggests that perhaps the next century will see the development of lay convents which will serve our successors as temporary asylums for restoring their forces, calming their nerves, and ret tempering their wills for the struggles of the coming year.

The report includes an interesting discussion of the differential diagnosis between functional and organic disease. Dr. Ross points out that first there is the difficulty of deciding whether organic disease is present; secondly, there is the more specialized difficulty of deciding whether, if present, it is responsible for the symptoms presented by the patient, and if responsible at all, whether in part or altogether. The factors responsible for the production of morbid states of mind are, of course, so complex that it is difficult to assign a predominant part to any one of them in a number of cases. A careful examination of the nervous system, with attention to the diagnostic criteria indicated by Dr. Ross, should in the majority of cases render it impossible to confuse organic disease of the nervous system with a psycho-neurosis. A much more difficult matter, and one which is to be considered in a later report, is to determine in the early stage of a mental disorder the category in which it should be placed. Thus in many cases it is hard to state with precision whether a patient is the subject of a neurosis or of a psychosis such as dementia precox or paranoia. There are probably no absolute criteria which justify a confident diagnosis in the incipient stages, though the impenetrability, lack of co-operation, reticence, and emotional poverty of the precocious dement, in contrast to the frankness, desire to talk of his case, emotionalism, and dependence of the psycho-neurotic will probably afford diagnostic clues to the experienced psychiatrist. Another difficulty arises from the fact that a typical psycho-neurosis may develop into a severe and incurable psychosis. This is often observed in the obsessional neurosis, which is in any case a form of malady particularly resistant to treatment. Thus a patient who has suffered from obsessions for many years may develop a paranoid psychosis or a profound melancholia with fantastic delusions of unworthiness; still more curiously, and more rarely, a paranoiac with ideas of reference may lose these delusions and develop into a typical hypochondriac. We refer to these facts in order to point out how difficult it is to predict the course or outcome of mental disorder, and to emphasize the importance of submitting cases to treatment before symptoms are fully developed. Not only will this render the possibilities of recovery greater before the disease is confirmed, but it will enable the psychiatrist to study the symptoms of incipient mental disease and thereby to gain better insight into their significance from the prognostic point of view.

It is evident from the three reports which have already been published on the work at the Cassel Hospital that these problems are engaging the attention of the medical staff, and it is much to be desired that further clinics of a similar kind may be developed,

not only for those who are in a position to pay for their nursing and treatment, but others connected with the general hospitals or under the control of the health authorities.

### THE LENGTHENED TRAINING OF THE MIDWIFE.

As the British Medical Association, in its evidence before the Royal Commission on National Health Insurance, has made "an efficient service of registered midwives" one of the conditions for its maternity scheme, the rules for the extended training of midwives recently issued by the Central Midwives Board for England and Wales, and the explanatory memorandum accompanying them, have a special interest for members of the Association at the present moment.

The period of training has been increased from six to twelve months for the previously untrained woman, and from four to six months for the fully trained nurse. This differentiation in the degree of lengthening may be justified on the ground that the trained nurse comes to her midwifery work already drilled in the ritual of surgical cleanliness—that part of the training which calls for intensive and continuous discipline until an instinctive habit is acquired. Possibly this halving of the period of study in favour of the trained nurse marks a stage towards making nursing training an essential preliminary to that of a midwife. The number of cases to be "personally delivered" and nursed remains at twenty as before, and one reason for the Board making no increase has been the very sound one of not encroaching further on the already too scanty material for the training of medical students. The memorandum, however, emphasizes the fact that twenty is to be regarded as the minimum number, and that it is expected that the pupil will deliver more, especially in institutions with a small number of cases, so as to compensate for the less continuous experience and less frequent impressions. Another new proviso is that besides the cases actually delivered, the pupil must be certified as having "witnessed not fewer than ten labours," so that she will have learnt what is expected of her before taking her twenty personal deliveries. The most striking change, however, is that five of those twenty cases must be attended within a hospital, and of the remaining fifteen at least five must be attended in the patient's home, with a corresponding proviso that of the twenty lying-in women to be nursed at least five must be nursed in their own homes. This last-mentioned point in the new rules should appeal particularly to the general practitioner who has to carry out the domiciliary practice of midwifery and work with the midwife, because its object, as stated in the memorandum, is that the pupil may learn "how to apply hospital methods to the more difficult circumstances of the patient's home, how to improvise and make the best of what she finds there," as well as how to discharge other duties that may not come to her notice in hospital, such as "her relations with, and duties to, the local health authority and co-operation with private medical practitioners." Space does not permit us to call attention here to other modifications in the rules, which seem well designed to meet their purpose in training women for the maternity service of the country, but it may be as well to note that the antenatal examination of twenty pregnant women is included in the certificates for admission to examination.

Even a cursory study of these regulations, and

particularly of the memorandum, which endeavours to interpret the spirit rather than the letter of the rules, will serve to emphasize the remarkable change that has followed the passing of the Midwives Act of 1902. Save in exceptional instances, the midwives of that period, though attending more than half of the births in the country, were untrained and unsupervised. To this day nearly 20 per cent. of those in independent practice are still of the old order, their names having been placed on the roll because they were *bona fide* in practice at the time the Act was passed. The training meanwhile has advanced by stages from three months—often taken as an apprenticeship to a midwife in practice—to a year's curriculum as set out in these regulations, with service both in a hospital and in the homes of the patients. Experience, however, has shown that it is much easier to turn out trained women than to get them to follow their profession as the Act intended. A large proportion of those taking the training laid down by the Central Midwives Board and passing its examination have no intention of practising as midwives. The qualification is useful to them as maternity nurses, in obtaining positions as health visitors and other appointments; but the work of a midwife is too strenuous, the responsibilities too great, and the prospects and economic return not such as to attract the more educated and highly trained woman. The recognition of her professional status by the Act has been paid for by the midwife by a close supervision of her practice, and by an amount of form-filling and "red-tape" that must excite the sympathy of the insurance practitioner.

The more difficult problem of distributing the services of these well trained midwives throughout the country so as to make them available wherever required is one that must be solved by the public and the health authorities responsible for the local administration of the Midwives and Maternity and Child Welfare Acts. Although something has been done under these Acts and by voluntary effort, such as the Queen Victoria Jubilee Institute and county nursing associations, only its fringe has been attacked; and until this aspect has been faced and some solution found, the degree of benefit from these regulations that will reach the mothers and infants of the country will be but a fraction of what it ought to be.

### THE INTER-STATE POST-GRADUATE ASSEMBLY.

It was said many times over during the meeting of the Inter-State Post-Graduate Assembly in London last week (of which we conclude our report at page 1086) that Medicine has no national frontiers. It may have no national frontiers, but very often at congresses in which different nations take part certain linguistic frontiers are very evident, and only a few specially gifted people hold the necessary passports. In a gathering of British and American medical men, however, this barrier does not obtrude itself, and there can be not merely amity but perfect understanding. The numerous lecturers last week never found it necessary to go back on themselves and recast a phrase because they were not addressing an English-speaking audience or to explain an idiom. They must have felt themselves being warmed, too, by the evident quickness of apprehension and appreciativeness of those they addressed. Not often do lecturers have audiences, especially consisting of the citizens of another country, so eager and co-operative.

The visitors were tireless in their search for instruction. In spite of very strenuous mornings, no flagging was permitted in the afternoons. If any hospitals made preparations for visitors and none came—which did happen in at least one instance—it was due to no negligence or disrespect on the part of the Americans, but simply to a breakdown of one item of the arrangements; and when one considers what an enormous amount of organization such a meeting entailed, it is a wonder that more breakdowns did not occur. On the side of the hosts there was an excusable pride in what this old country had to show. They took it as a great compliment that visitors should have come so many days' journey to explore their possessions, intellectual and other. One doctor from California, who had left his home on May 10th and had been three weeks on the journey, told an Englishman that, apart from what he hoped to hear and see on the professional side, he had two great ambitions in visiting this country, and had fulfilled both; one was to go to Stratford-on-Avon and the other to see the Rosetta stone at the British Museum. The reverence which the visitors showed for our traditions and our ancient things was most noteworthy.

The outstanding personality of the Assembly was Dr. Charles Mayo, of the famous clinic at Rochester, Minnesota—a man who dominated any company, though not by any assertiveness on his own part. The one anxiety of Dr. Mayo, who described himself as "the brother of William James Mayo," seemed all through to be to express as often as possible his gratitude for all that had been done for him and his friends. The visitors have certainly left behind them in London, among all with whom they came in contact—and we do not doubt that they will produce the same impression in Edinburgh and the other centres they are visiting—a greater friendliness for their country. Tennyson's lines were quoted at the Guildhall banquet:

Gigantic daughter of the West,  
We drink to thee across the flood,  
We know thee best, we love thee best,  
For art thou not of English blood?

But this was felt to be not an occasion for grandiloquent protestations of Anglo-American unity, but rather for good fellowship and companionableness. So far as could be told, the visitors represented the general practitioners of all the States from one seaboard to the other. A very large proportion of them came, not from the great cities, but from relatively small communities of the Middle West. What they gathered in the way of fresh instruction will be carried to wider circles through their medical societies, the local units of the American Medical Association, to which three-fourths of them belong. We only hope that their recollections of us will be as kindly as our recollections of them. A permanent result of the visit in this country may be some further approach to the ideal which Dr. Franklin Martin urged at the Guildhall banquet—that of making London the post-graduate centre of the English-speaking world.

On Thursday, June 25th, the President will give an evening party at the Royal College of Physicians of London to commemorate the centenary of the opening of the present College building, during the long presidency of Sir Henry Hallford, to whose influence it was mainly due that the site at the corner of Trafalgar Square and Pall Mall East was placed at the disposal of the College.

## THE PRESIDENT'S VISIT TO CANADA AND THE UNITED STATES.

Mr. J. BASIL HALL, M.Chir., F.R.C.S., President of the British Medical Association, during his recent tour of Canada visited Montreal, Kingston, Peterborough, Toronto, Buffalo, Hamilton, Winnipeg, Ottawa, and the Niagara district. In Toronto he addressed the Academy of Medicine on the overgrowth of modern specialism, and his lecture is described by an officer of the Academy as "one of the most eloquent and inspiring that has been delivered before that body; his visit will undoubtedly strengthen the bonds of sympathy and esteem uniting the British and Canadian Medical Associations." While in Toronto the President also addressed the Ontario Medical Association and the Medical Alumni Association of the University of Toronto. In the United States he has been entertained by the Philadelphia Medical Club, and he addressed the annual meeting of the American Medical Association in Atlantic City. Our contemporary the *Journal of the American Medical Association*, after referring in an editorial article to Mr. Basil Hall's visit to the headquarters of the association in Chicago on May 11th, quotes from his Presidential Address last summer at Bradford, and concludes thus: "At a time when the American medical profession is concerned with similar problems, we are exceptionally fortunate in the visit of a British confrere with a real sympathy for the problems of the general practitioner." Immediately after his return to this country the President, on June 10th, attended a meeting of the Council of the British Medical Association. He was very warmly received, and in the course of a few words spoke of the fine welcome he had met in Canada and in all the other centres he visited. He was, he said, sure that his visit had done good. During the midday recess the members of the Council were entertained to luncheon at the Grand Hotel by the Chairman, whose health was proposed by Dr. Braekenhury. In the course of a brief response Dr. Bolam referred to the great debt the Association owed to many older members, some of whom he was glad to see present; the possibility of acquiring the new house was due to their courage and foresight.

## MEDICAL EDUCATION IN WALES.

THE progress of medical education in Wales can scarcely fail to be impeded by the decision of a recent meeting of the Court of Governors of the University College of South Wales and Monmouthshire, Cardiff, against the separation of the National School of Medicine from the local college. It is true that the court was by no means fully attended, and that the decision arrived at challenges no less an authority than the Privy Council; nevertheless the decision was made, and the next move seems to rest with the Privy Council. The history of the present unfortunate situation is long and complicated. The beginnings of medical education in Wales date back to 1893, when departments of anatomy and physiology were formed at Cardiff College. In 1909 the Treasury gave a special grant to the medical school, which led to the establishment of a chair of pathology and bacteriology; and in response to a general demand the complete "final" school was brought into being soon after the war. In the meantime the urgent need was felt for the reorganization of the University of Wales itself, and in 1916, at the request of the university and colleges, a Royal Commission on University Education in Wales was appointed, with Lord Haldane as chairman. The university and colleges promised to abide by the decisions of the Government based on the findings of the Commission. In their final report the Commissioners recommended the organization of the medical school as a constituent college

of the university, to be governed under the university by a council and senate of its own. This recommendation has since been endorsed by the Faculty of Medicine, the Council of the University of Wales, and the Privy Council. The Council of the University has drawn up a draft scheme for the constitution of the National School of Medicine as a school of the university, which has been submitted to and approved by the Privy Council, but the local college refuses to accept it. The situation is further complicated by the fact that Cardiff College itself is petitioning the Privy Council for a supplemental charter, which, however, the Lords of the Committee refuse to advise His Majesty to grant till the clauses dealing with the School of Medicine are deleted, since "they are convinced that the only satisfactory solution of the problem is to give the school an independent position under the National University." While the desire of Cardiff College to retain within itself its most powerful faculty is natural and understandable, it is just as clear that this retention is directly against the wishes of the medical faculty and the rest of Wales. Incidentally, the college itself would appear to appreciate that its progeny has outgrown its nest, since, while all professors of other faculties have a seat on the senate of the college, only a limited number of the professors of the medical faculty are accorded this privilege. In other words, the other faculties would seem to fear the numerical power of their medical brothers, which is surely acknowledging that the medical school is sufficiently grown up to move into a house of its own. The School of Medicine receives generous financial support from the whole of Wales because it is a national school; if it is to remain an adjunct of Cardiff College this aid will, there can be little doubt, be withdrawn. On March 25th last Swansea Town Council affirmed its approval of the principle of a national school of medicine, and decided that its contribution to the school should be paid into a suspense account, on the distinct understanding that if the school did not become part of the University of Wales the contribution should be refunded to the borough. It seems likely that the rest of Wales will follow Swansea's lead—no national school, no national contributions—and Cardiff College may be placed in the unpleasant position of having to appeal to a Government which it has flouted for financial support for a school which has been impoverished by its short-sighted policy.

#### ENCEPHALITIS PERIAXIALIS.

In 1912 Schilder described a curious form of diffuse sclerosis of the brain to which he gave the name of "encephalitis periaxialis diffusa." Isolated records already existed of cases in which a similar pathological picture had been found, and since the publication of Schilder's paper between twenty and thirty cases of the same sort have been described, chiefly by German writers. A summary of the literature, together with descriptions of new cases, is contained in two articles in *Brain* (1924, Part IV)—one by Professor L. Bouman of Amsterdam, and the other by Drs. James Collier and J. G. Greenfield of the National Hospital for the Paralysed and Epileptic, Queen Square, London. The pathological appearances are remarkable and quite distinctive, but an altogether new interest has been added to the subject by the fact that a fairly constant clinical picture can now be associated with the disease, since Dr. Collier demonstrated one of his cases during life as an example of Schilder's disease. He was led to make the diagnosis by the clinical resemblance which the case bore to one he had observed in 1902 in the wards of the late Dr. Beever at the Queen Square Hospital; this case presented pathological appearances characteristic of the condition described ten years later by Schilder. The subjects of this disease are for the

most part children or young adults, and no predisposing factors have been noted. The onset is fairly abrupt, and the earliest symptoms are usually disturbances of vision of a kind suggestive of a lesion in the occipital region of the brain. Most of the patients complain simply of a rapid failure of vision, but in a few the loss of vision has been preceded by visual hallucinations, inability to estimate distances, or other signs of visual disorientation. It may be found on examination that the loss of visual acuity affects equally the whole of the visual fields, or that homonymous hemianopia is present; in one of Schilder's cases the blindness affected at first the lower half of each field, corresponding to a lesion in the upper part of each occipital lobe. The pupils continue to show the normal reflex contraction to light—an important sign that the blindness is occipital in origin. A mild degree of optic neuritis has been found in several cases, and has led to the diagnosis of intracranial tumour; its occurrence adds considerably to the difficulty of diagnosis, but the fact that it remains stationary or passes off altogether while other symptoms advance rapidly is a strong argument against the presence of a tumour. Along with the loss of vision there is usually headache and in some cases vomiting. In typical cases the earlier symptoms are followed more or less rapidly by evidences of involvement of the parietal, temporal, and finally frontal regions of the brain. Anaesthesia of cortical type in the form of astereognosis, and unsteadiness of gait from loss of sense of position, may be succeeded or accompanied by progressive deafness. Sooner or later in all cases spastic paralysis develops in the limbs of one or both sides; the legs are usually first affected, and the development of an extensor plantar response is an early sign in most cases. Epileptiform fits are a common symptom, and may occur early. Some degree of progressive mental deterioration is invariable, and may set in early, leading in most cases to a condition of complete dementia. The duration of the illness averaged in seventeen cases ten and a half months, the extreme limits being forty-one days and thirty-six months; in one case recorded by Marie there was, however, an almost complete remission for nine years. In a minority of the cases the order of occurrence of the symptoms is not typical, and visual disturbance may be wholly absent; here the main features are spastic paralysis, fits, and mental changes, and it is difficult to see how the diagnosis could be made with any degree of certainty. The Wassermann reaction was positive in one case only, and the only abnormalities recorded in the cerebro-spinal fluid have been an increase of albumin and a slight excess of lymphocytes. There is usually no fever throughout the illness. The appearance of the brain after death is quite unlike that seen in any other affection. Almost the whole of the white matter of both hemispheres is converted into a pale brown translucent substance of firm consistency, the condition being typically most advanced in the occipital region. In the cases in which vision was unaffected the lesions in the brain corresponded in position with the symptoms present during life, and the occipital lobes were relatively intact. The spread of the disease forwards from the occipital region corresponds with the march of the symptoms, and the frontal area, the basal ganglia, and the brain stem are usually affected late or in slight degree. The cortical grey matter and the arcuate bands of nerve fibres immediately below the cortex are either spared entirely or affected to a moderate degree late in the disease. This fact seems to point to the conclusion that the white matter is affected by some noxious substance, possibly organismal, brought to it by the blood vessels, since the cortex and arcuate fibres receive their blood supply from the surface of the brain, and not from the deep vessels which supply the white matter. The microscopical picture is characterized by an extensive destruction of the myelin sheaths of the nerve fibres in the

white matter, while the axis-cylinders remain more or less intact till the later stages of the disease, when they also are destroyed. In addition there is a widespread overgrowth of neuroglial fibrils, and a general infiltration of the white matter, especially around the blood vessels, with cells of various types. Many of these are round cells resembling lymphocytes, but there are also present compound granular corpuscles concerned in the removal of the myelin, and in addition groups of giant cells of a character probably peculiar to this disease. The histological appearances, especially the preservation of the axis-cylinders which gave rise to the name proposed by Schilder, are somewhat similar to those of disseminated sclerosis, but the distribution of the lesions and the clinical features of the illness are totally unlike that disease.

#### THE ACTION OF GOLD SALTS IN EXPERIMENTAL TUBERCULOSIS.

PROFESSOR OLUF BANG, who has been investigating the action of such gold salts as sanoerysin, contributed to the journal of the Danish Medical Association, *Ugeskrift for Læger*, for May 14th an account of recent experiments, which appear to show that these gold salts have no bactericidal action *in vitro* even in strong solutions, and are of no value in experimental tuberculosis in rabbits. The salts tested were sodium aurothiosulphate and sodium aurichloride; it is stated that the former was subsequently found to be identical with sanoerysin. Early in October, 1924, to each of eight rabbits was given an intravenous injection of tubercle bacilli of bovine origin, followed in six animals by the administration of gold salts, the other two serving as controls. One of the rabbits treated with sodium aurichloride and one of the controls survived the infection, and there was no evidence that the intravenous injection of gold had been beneficial. In a second series of tests nine rabbits were infected with bovine tubercle bacilli by the intravenous route and eight subcutaneously; four of the seventeen served as controls. The gold was given by intravenous injection immediately or five days after infection. The treatment had no effect on the disease, and of the animals infected by intravenous injection the controls lived longest. A curious observation was made in the case of a rabbit given a second injection of sodium aurichloride: as this was proceeding the rabbit suddenly became very restless and seemed to be dying. The injection of gold was discontinued, and 1 c.cm. of Moellgaard's serum was injected, when the rabbit revived at once. Later on it again began to look ill, but a second dose of serum had a similar revivifying effect, and next day the rabbit was perfectly well. It was found that the preparation of sodium aurichloride given on this occasion was more acid than those previously used. Next day the same solution of sodium aurichloride was injected into a rabbit in which the absence of tuberculosis was subsequently determined after death. This rabbit collapsed immediately, but recovered after an injection of serum. Professor Bang suggests that the action of serum in cases of shock caused by sodium aurichloride is unconnected with tuberculosis, and he is very sceptical about the theory that Moellgaard's serum prevents shock in tuberculous animals by neutralizing tuberculin supposed to have been set free by the action of sanoerysin on tubercle bacilli. In a third series of tests the dosage and virulence of the injected tubercle bacilli were reduced, and sanoerysin was administered before as well as after the experimental infection. But the four rabbits thus treated fared no better than the two controls. In a fourth series of tests seven rabbits were used, and only a few tubercle bacilli were introduced by the intravenous injection of an emulsion of tuberculous tissue. Only two of the rabbits were dead at the time of

writing, but in this series also there was no evidence to indicate that the gold treatment had a beneficial effect. After describing experiments with gold salts *in vitro*, Professor Bang states that sodium aurothiosulphate (Gjaldback) does not interfere with the growth of tubercle bacilli in a 1 in 2,000 solution, and sanoerysin (Moellgaard) does not do so in a 1 in 3,200 solution. As for the alleged bactericidal action of sanoerysin on tubercle bacilli, Professor Bang describes a test indicating that sanoerysin in a 1 per cent. solution at a temperature of 38° C. fails to kill tubercle bacilli in the course of eleven days. He concludes that the gold salts investigated have no specific action on tubercle bacilli, and that any curative action resulting from the use of sanoerysin in human tuberculosis must depend on other factors. Professor Moellgaard has answered Professor Bang's criticisms in a long letter published in *Ugeskrift for Læger* for May 21st. His points may thus be summarized. Tests *in vitro* of the bactericidal and growth-inhibiting actions of a chemotherapeutic remedy are valueless, as chemotherapy is not internal antiseptis, witness the inability of such drugs as atoxyl, salvarsan, and Bayer 205 to kill in a test tube in a dilute solution the germs which they destroy *in vivo*. The shock observed by Bang in the case of the rabbit which recovered when given serum was a pure drug shock, such as may follow the administration of salvarsan, and has nothing to do with toxin shock following the injection of a chemotherapeutic remedy in a highly infected animal. Bang's method of infection with pus does not ensure a uniform dose of tubercle bacilli, and may entail a mixed instead of a pure experimental infection. The sodium aurothiosulphate prepared by Gjaldback is not necessarily identical with sanoerysin, and negative experiments with the former do not, therefore, at once invalidate the claims made on behalf of the latter. Bang's tests *in vivo* with sanoerysin itself were limited to six rabbits, none of which was treated with serum, and it is doubtful whether the optimum dosage was given; and even if sanoerysin proves to be ineffective in the experimental tuberculosis of rabbits, it does not necessarily follow that it is ineffective in the tuberculosis of other animals and man. Moellgaard concludes with the generalization that as great reserve and caution should be practised in the publication of negative findings and destructive criticism as in that of positive findings and therapeutic claims; and he does not admit that Bang's work on rabbits has upset the observations and conclusions based on four years of conscientious experimental work.

#### SWINE ERYSIPELAS AND MAN.

ONE of the most widespread porcine diseases in this country is the so-called swine erysipelas. Unlike swine fever, it is not a notifiable disease; but although exact statistics are not at present available, there can be no doubt that it is a very serious source of loss to pig-breeders. Its importance is intensified by the fact that the causal organism is capable of attacking human beings. It is a Gram-positive, facultative anaerobic, immobile bacillus, morphologically identical with the bacillus of mouse septicaemia. It is non-sporulating, but nevertheless has very considerable powers of resistance, and apparently can exist as a saprophyte in the soil. In pigs acute and chronic forms of the disease are encountered. In the acute form there is fever, purplish discoloration of the skin, and hæmorrhagic visceral lesions; while in the chronic type, in addition to the skin coloration, there are frequently seen arthritis and a verrucose endocarditis—the vegetations containing immense numbers of the bacillus. A serum obtained from the horse with or without a vaccine has been successfully used in the prevention of the disease; the serum has also been used for treatment. In man the lesions of the heart are unknown;

and in general the disease runs a much more benign course than in pigs. Many cases have been reported at one time or another. Cameron<sup>1</sup> recently referred to a case in one of the inspectors of the Ministry of Agriculture; while Cotoni<sup>2</sup> and Cauchemez<sup>3</sup> have recently described the symptoms as seen in themselves. Numerous other cases have been reported in Germany. All the cases in man have been traced to direct inoculation from a porcine source. In the pig infection is generally by ingestion. The symptoms vary, but usually a slightly painful erythema is observed within forty-eight hours of infection. The swelling extends up the arm—the primary lesions in all recorded instances have been on the fingers—and there is a more or less generalized lymphangitis of the extremity; for some days the patient suffers from a low fever and general malaise and fatigue. In some instances encephalitis has been spontaneous; in others a subcutaneous injection of antiserum has materially assisted the cure—in Cauchemez's own case the swelling disappeared within seven hours after the injection and the subsequent recovery was rapid. In addition to its transmissibility to man, the disease is of considerable economic importance. It is apparently reaching epizootic proportions in some parts of England this year, and is causing great losses. If energetic measures are adopted by the Ministry of Agriculture, there should be a considerable improvement in the situation and a diminution in the probability of human infection.

#### THE ROYAL FREE HOSPITAL.

THE Royal Free Hospital, in Gray's Inn Road, is, we believe, the only hospital in Great Britain which enjoys the specific distinction of being the hospital of a medical school for women. It was the consent of the managers and staff of the hospital to occupy the position which made possible the London School of Medicine for Women, and during the forty or more years the connexion has existed there has grown up a strong feeling of loyalty among the old students of the school. The dean of the school, Dame Aldrich-Blake, M.D., in responding to the toast of "The Hospital" at a festival dinner given on Tuesday evening at the Guildhall, London, dwelt on this point, and said that in this way the fame and name of the hospital was carried into every corner of the British Empire. The toast had been given by Mr. J. H. Thomas, M.P., who, beginning in a humorous vein, went on to make a really eloquent appeal, during which he recalled that the hospital had been founded by Dr. William Marsden in 1828, and moved to its present site in 1840. While there was, he said, difference of opinion as to whether hospitals should be supported by voluntary contributions or by the State, there was no difference of opinion that the hospital work must go on. Lord Riddell, who was in the chair, and who is president of the hospital, said that at the present time it almost seemed that any hospital desiring to raise money must either be falling down, or about to close a number of wards, or have a substantial overdraft. The Royal Free Hospital was not falling down, nor were any of its wards to be closed; on the contrary, a special appeal was made for £50,000 to build a ward for children. It had, however, a substantial bank overdraft. Since its foundation the hospital had treated four million patients, and during all the ninety-eight years of its existence had been able to command the support of generous benefactors, among whom at the present day very special thanks were due to Mr. Alfred Langton, one of the hospital's greatest friends. Lord Riddell was very warmly received, as was his reference to Mr. Langton. The toast of "The Guests"

was given by Dr. Walter Carr, consulting physician to the hospital, and acknowledged by Lord Jessel, formerly M.P. for St. Pancras, and Mr. C. T. Cramp, general secretary of the National Union of Railwaymen. Sir Charles Wakefield, an alderman of the City of London, and formerly Lord Mayor of London, proposed "The Medical Profession"; this was acknowledged by Sir Humphry Rolleston, Bart., President of the Royal College of Physicians, and Sir Squire Sprigge, M.D. It was announced that subscriptions amounting to £21,250, including a gift of £5,000 from Mr. Alfred Langton, had been received in connexion with the festival dinner, and Lord Riddell said that he would make the amount up to £25,000. We fervently hope that the whole amount required will shortly be received, for it seems to us something of an anachronism that the hospital of a medical school, especially perhaps a medical school for women, should lack children's wards.

#### HEALTH AND THE LEAGUE OF NATIONS.

IN a brief foreword to his little volume *What the League of Nations Is*,<sup>1</sup> Mr. Wilson Harris explains that no such publication already exists in small compass and at a reasonable figure. Everyone doubtless thinks he knows a good deal about the League, but after perusal of this admirable work he will find that concise and specific knowledge has displaced his vague acquaintance with the subject. The chapter that particularly interests a medical reader is devoted to the world's health. Article XXIII of the Covenant requires that the League shall "take steps in matters of international concern for the prevention and control of disease." Its organization for that, as for some other purposes, consists of a Health Advisory Council, a Health Committee, and a Health Section of the Secretariat, the Committee being the chief agency. Having neither personnel nor funds for large activities, its main function is to co-ordinate and direct national effort, though at the very beginning it had to participate actively in the campaign against typhus in Eastern Europe. For that special purpose voluntary contributions by Governments provided a fund of about £200,000, so that doctors, hospitals, and drugs were supplied for the emergency at the same time that the countries concerned had the benefit of an object lesson in the prevention and control of disease. Also, an office has had to be established as far away as Singapore to fight the origins of disease in the Far East, under direction from Geneva. Uniformity of standards in the use of medical terms and in the production of serums is manifestly of international importance, and for this the State Laboratory at Copenhagen has been made responsible under the scheme of the League. The same remarks apply to vital statistics and statistical methods. Cancer, malaria, sleeping sickness, and tuberculosis are subjects of study. Thanks to funds provided by the Rockefeller Foundation, health officials of different countries have been organized into parties of twenty or thirty, to receive a two or three months' course of instruction in the administration of selected countries, including Great Britain. An example of other activities is to be found in the inoculation against typhus of half a million refugees pouring into Greece from Asia Minor after the Turkish victory over the army of Greece. Infectious diseases pay no heed to national boundaries, and the League endeavours to establish a system of mutual protection. In the other chapters of his book Mr. Wilson Harris deals with such subjects as the Court of International Justice, the armaments problem, the reconstruction of Europe, the Saar and Danzig, and the protection of the rights of small nations.

## UNIVERSITY OF BRISTOL.

## ROYAL OPENING OF THE NEW BUILDINGS.

On Tuesday, June 9th, the King and Queen visited Bristol to open the new buildings of the University provided by the munificence of the Wills family. Bristol is the youngest of the English universities, for its charter dates only from 1909. When members of the British Medical Association visit the sister city of Bath next month they will have an opportunity of inspecting the University.

## ORIGINS OF THE UNIVERSITY.

In anticipation of this important event Professor J. A. Nixon, C.M.G., M.D., has contributed to the *Bristol Medico-Chirurgical Journal* an article, with illustrations, on the past and present of the University, with special reference to the Bristol Medical School. Higher learning, he says, met with no encouragement in Bristol until the decay of the Barber Surgeons' Company early in the eighteenth century stimulated some of the infirmary staff to give anatomical and other lectures to their surgical pupils. In 1816 Dr. J. C. Prichard conceived the project of founding a medical school in connexion with the infirmary. By 1830 various independent courses of lectures had been combined to form two recognized medical schools—the School of Anatomy and Medicine and the Bristol Medical and Surgical School. In 1833 these were amalgamated to form the Bristol Medical School. When the University College was founded in 1877 some of the lecturers in the Medical School advocated complete incorporation of the new school with the College, but this proposal was defeated and the Medical School remained autonomous until 1892, when it was incorporated in the College. When seventeen years later King Edward VII granted a charter to found the University of Bristol by merging University College and the Merchant Venturers' Technical College, the incorporation of the Medical School in the new university was not even then made complete. At length, in 1922, the whole medical curriculum came under University management.

"Thus the Bristol Medical School with its long and honourable tradition continues as one of the most vigorous faculties in the university to whose foundation it had so actively contributed, even if at times it has dissembled its filial affection and pride by a certain degree of independence."

Professor Nixon follows this historical note with a brief review of the opportunities and advantages which the medical student can enjoy to-day in Bristol. The departments of chemistry, biology, physics, anatomy, physiology, and pathology are splendidly equipped. As for the departments of medicine, surgery, obstetrics, ophthalmology, otology, and laryngology, although these find scanty accommodation in the University buildings, "they can spread their wings wider and more freely in the great hospitals of the city." In the new buildings, however, there is a fine Medical Library, containing collections of books which

formed the separate libraries of the Royal Infirmary, the General Hospital, the Bristol Medico-Chirurgical Society, and University College.

In conclusion Professor Nixon points out the advantages offered by Bristol in the provision of halls of residence for undergraduates. Students who do not live at home are no longer compelled to find isolated and ill furnished lodgings. "The University of Bristol has from the outset aimed at being a residential university, and in the short space of sixteen years has succeeded in laying the foundation of true collegiate life for both men and women students."

## THE NEW UNIVERSITY BUILDINGS.

The new buildings, occupying the Queen's Road frontage of the central university site, are the gift of Sir George A. Wills and of his brother, the late Henry Herbert Wills, who died three years ago. The buildings constitute a memorial to the donors' father, Henry Overton Wills, founder of the University and its first Chancellor. Built of stone in Gothic style, they are surmounted by an imposing Memorial Tower, of which some idea may be gained from the illustrations on this page. This tower, 215 feet in height, which dominates the skyline of Park Street and overlooks the spires and cupolas of mediæval and eighteenth century Bristol, contains a lofty entrance hall with fan-vaulted roof and double flight of stone stairs; a striking feature of the interior is the founder's window. The entrance hall gives access to the Great Hall, a splendid chamber with carved oak panelling and hammer-beam roof, and an apse of fine proportions.

Other features of the new building are the Council Chamber, the administrative offices of the University, and the new premises set apart for the Faculty of Arts. It accommodates also two important libraries in a separate wing—the large general library, with its remarkable barrel roof, and the medical library referred to above.

The architect, Sir George Oatley—as is justly observed in a sumptuous book of the University of Bristol, published for the occasion—has followed the Gothic precedent of previous builders: a choice of style justified by the peculiar adaptability of a Gothic building to complex requirements on a somewhat crowded site. His work, however, shows no servile reproduction of fifteenth century forms. The Memorial Tower with its belfry—original in the solution

of the old problem how to set an octagon upon a square without leaving awkward corners—gives cohesion to the imposing mass of the exterior. Throughout the new buildings the balance of severity and ornament is carefully observed, both in masonry and in woodwork.

Within the octagonal belfry hangs a great bell weighing nearly 10 tons, and bearing an inscription from the Vulgate (Rev. vii, 12).

When, more than a year ago, we had an opportunity of inspecting this great work in progress, with the architect as guide, the idea came over us, as we climbed dizzy heights and scrambled among masses of stonework and forests of

Bristol University: Memorial and Arrowsmith Towers seen from Physics Laboratory.

beams, that we were back in the days of mediæval craftsmanship. Masons and carpenters one and all seemed to be working as their forefathers worked, each fashioning his piece of the fabric as though the success or failure of the whole turned on how he did the job that lay to his hand. The impression that remained was that the artificers of Bristol, conscious of their heritage, had entered into the spirit of the thing. This, as the younger generation would say, must be counted as one up to the architect, who, with boundless resources at his command—for where there are Wills there are ways—has risen to the height of a wonderful opportunity.

#### HALLS OF RESIDENCE.

A large proportion of Bristol students are drawn from the towns and villages of the West and South-West of England, and the aim of the University from the first has been to give such students, and any others who wish for them, the unquestioned advantages of a residential system, thus providing the means of a true corporate life. The authorities recognize how much is to be gained from the influence of a large nucleus of resident students, suitably housed and organized, on the spirit of the University as a whole.

The women students of the University have been fortunate from the outset; a private benefaction enabled the University to purchase and equip for their reception the delightful property of Clifton Hill House. To this has been added the adjoining premises of Callander House and grounds, and another mansion near at hand known as the Manor House. Besides these there are four smaller halls of residence for women.

For the reception of male students Canynge Hall and Mortimer House were instituted in 1919 and 1922. A further and most important step on this side of University development is the projected establishment of a new residential college for men on an estate of twenty-five acres across the Clifton Downs, not far from the University athletic grounds. This estate was the last gift in his lifetime of H. H. Wills, and the buildings are to be given by Sir George Wills in memory of his brother. The plans, as our reproduction of the architect's drawing shows, are already prepared; they foreshadow a complete scheme of collegiate life, such as is practicable only where buildings are originally designed for the purpose. Thus Bristol, thanks to its benefactors, will be able to provide for its undergraduates a full residential college life, such as hitherto has been the peculiar asset of the ancient universities.

#### THE OPENING CEREMONY.

When the King and Queen arrived at Temple Meads, Bristol, at noon on Tuesday they were met by the High Steward of Bristol, the Duke of Beaufort, and Lord Beauchamp, Lord Lieutenant of Gloucestershire, who presented the Lord Mayor and other officials to the King. Their Majesties, accompanied by Lord Eustace Percy, President of the Board of Education, then drove through cheering crowds to the Council House, where the Corporation presented an address of welcome. In his reply the King said that the advance of education was a traditional virtue in Bristol, and that the merchants of the sixteenth century and afterwards who made the city famous in exploration and trade were also great founders of schools. At one time it had been thought that a university town was the seat of a university and nothing else, but it had been the most characteristic feature in the modern development of higher education that new universities had been founded in busy and populous centres. This was in the best interests of both

learning and business, for the interaction of the two was stimulating to each.

After luncheon their Majesties proceeded to the University, where the University procession was formed and entered the Great Hall, headed by the architect and contractor and representatives of the workmen. The Chancellor of the University, Lord Haldane, presented an address, in the course of which it was said that "It is our happy lot and duty to cultivate and encourage learning both by imparting knowledge to those who seek it, and not less by providing facilities for its development through maturer study and research." It was the part of a university to unite in a common life and inspire with a single ideal persons whose fortunes had been unequal. The University was conscious also that it was incumbent upon it to bring science to the aid of industry, and in that region particularly to the aid of the ancient and fundamental industry of agriculture, in which their Majesties had shown so keen and so expert an interest.

The King, in his reply, said it gave him great pleasure to open the magnificent buildings which had been erected in memory of the first Chancellor by his sons, one of whom, to the deep regret of all, had not lived to see the completion of a work to which he had devoted, not only wealth, but many years of thought and care. He had, however, left an inspiring example of devotion to a high ideal. The lofty ideals of the University which had been outlined in the address united the youngest and the oldest of our universities in an undivided fellowship of national service. "To hold in trust," the King said, "for the common use the treasures of past thought; to provide for the creative minds of the present a congenial and stimulating home; to give to all the opportunity of a liberal education in the arts and sciences; to animate men and women with worthy ideals of clear thinking and social usefulness; to spread the pure light of disinterested studies over an ever-widening circle—these

Quadrangle of Projected Residential College for Men.

are some of the essential and ennobling duties of the universities. Their responsibilities are heavy as their opportunities are great; and they can only rise to the full measure of their task if they be strong in public sympathy and support. I am, therefore, glad to hear that, not only the city of Bristol, but also neighbouring counties and important cities, are giving practical proof of a firm belief in the value of the work of this University, and evincing a determination to help in the extension of that work to ever higher levels of achievement."

An address was then presented by the Master of the Society of Merchant Venturers. The King, in reply, said that the society had a striking history, in which the names of Colston and Whitson were proof that the great merchants of the past had a just appreciation of the value of knowledge. The schools of Colston's foundation were still flourishing, but when the educational system of Bristol grew in direction Colston would never have foreseen the Merchant Venturers showed themselves faithful to their old traditions in the new circumstances. The facilities provided in their Technical College were freely used, and the part the society had taken in founding the University of Bristol was fully appreciated. Recent and happy experience showed that the society's old traditions of munificence were not extinct, and that there were still families in Bristol ready to emulate the generosity of earlier benefactors.

The King then, at the invitation of the Chancellor, declared "the University building open as a memorial to the founder for the uses of university education for ever." When the Royal party had made a tour of the building the procession re-formed and passed through cheering crowds to the station.

## RESEARCH DEFENCE SOCIETY.

## ANNUAL MEETING.

THE annual meeting of the Research Defence Society was held on June 9th under the presidency of Lord LAMINGTON. The report showed that during the past year the society had had relatively a peaceful time, though a good deal of work had been done to educate the public in the need for vaccination against small-pox. Dr. G. P. Crowden had been appointed honorary secretary (in place of Dr. Harris, who had resigned owing to the increasing calls on his time), and Dr. A. Salter, M.P., parliamentary honorary secretary. The financial report, submitted by Sir DAVID FERRIER, showed a diminution both in income and expenditure. The income from subscriptions and donations amounted to little more than £70.

*Our Defences against Small-pox.*

Dr. R. A. Lyster (M.O.H. Hampshire) gave a lecture on our defences against small-pox. He said that generally in the campaign against those diseases which had a frightening effect on the public it was not difficult to make headway, but in the case of small-pox and venereal disease, owing to special circumstances, difficulties arose. Both were loathsome diseases, the secret of both of them was known, they were diseases easily prevented and easily exterminated, and yet both continued to exist, thanks to powerful influences against the effective employment of the measures which medical science had at its command. As soon as the secret of small-pox was discovered, the antiprevention crusade began, and a Dean of St. Paul's preached a sermon to prove that small-pox was an agent of the Almighty for keeping down the surplus population. The fight against disease had been constantly hindered by the idea that sooner or later some universal panacea would be discovered whereby disease itself would be abolished. The biggest unit of the antivaccination army believed that sanitation was such a panacea. But there would never be a universal panacea, because every disease had its own particular secret and key. The secret of venereal disease was personal disinfection; the secret of small-pox was immunization by vaccination—that is to say, an extremely mild and non-infectious form of the disease could give the same immunity, or approximately the same, as the disease itself. Many diseases—rabies, tetanus, diphtheria, enteric fever, among others—were combated by the production of immunity, and the triumphs in these cases were as noteworthy as in small-pox. Apart from the possession of the vital secret with regard to any diseases, only general measures could be taken, and these, while useful enough, might be of no avail in an epidemic.

Recently, in the *Times*, Mr. George Bernard Shaw had disputed the assertion that before vaccination small-pox was almost universal. It was true that there were no general official records, but local records did exist which upset Mr. Shaw's conclusion. In Kilmarnock from 1728 to 1764 the average population was 4,000, and 16 per cent. of all the deaths were due to small-pox; the average age of all the small-pox patients at death was 2½ years, and only 3 of the deaths were of persons over 20. At Chester a census was taken in 1775, when the population was 15,000, and only 1,060 of the persons alive in that year had not had small-pox. At Ware in 1772, in a population of 2,515, only 302 had not had small-pox. In the eighteenth century there was evidence that many parents in their panic deliberately inoculated themselves or their children from mild cases. Recently vaccinated persons were exempt from small-pox. Every epidemic told the same story. In the Nottingham epidemic of 1821-22 no vaccinated child took the disease. In the recent epidemic at Toronto no case of small-pox occurred among persons who had been vaccinated during the previous twelve years; there were no deaths at all in that epidemic among persons who had ever been vaccinated, whereas 71 per cent. of the unvaccinated cases died. He cited similar figures for the Gloucester epidemic of 1895 and the Poplar epidemic of 1922. With regard to the Gloucester epidemic, he quoted the report of Dr. John Campbell, the medical officer of health for that city at the time, to the effect that the disease raged at its worst in the area which was the most recently built and

the least densely populated—a fact which contradicted recent assertions. Dr. Lyster confessed himself baffled in his efforts to discover the scientific position of the antivaccinationist agitation. The propagandists on that side appeared to take refuge in a series of denials of scientific facts, and themselves brought forward alleged facts which lacked the necessary precision to permit of their being verified. Moreover, antivaccinationists contradicted one another; one party said that the almost universal incidence of small-pox in the eighteenth century was a myth, another party admitted its existence but said that it was due to bad sanitation. He himself had no quarrel with antivaccinationists on any other than the scientific ground. He gave them credit for high ideals and a desire for the public benefit. He asked only that they should give him similar credit. And he would like to see how far the antivaccinationists were prepared to prove the faith that was in them. Any medical school on the vaccination side would provide two dozen volunteers who, having been efficiently vaccinated, would welcome the opportunity of being brought into intimate contact with a number of typical and fairly severe small-pox cases. Was the antivaccinationist brigade prepared to put up a similar number of enthusiasts? Let them employ whatever prophylactic other than vaccination they chose, and then let them attend on small-pox cases, and let some independent body judge the results. The experiment might have interesting scientific consequences, and might even go far to settle this long-standing controversy. It was time that the bitterness and hostility between the two camps came to an end, and it could only do so by a scientific test to which both sides submitted.

## RUTHERFORD MORISON TESTIMONIAL.

THE following is the third and final list of subscriptions to this fund, the grand total of which, including subscriptions promised, amounts to £1,528.

## THIRD SUBSCRIPTION LIST.

- £32 10s.—Professor C. Saint (Newlands, C.P.).  
 £15 15s.—Dr. Mary S. Gordon (Grahamstown).  
 £10 10s.—Professor R. P. Ranken Lyle (Newcastle), Dr. W. Frank Wilson (Newcastle), Mr. F. C. Pybus (Newcastle), Mr. T. A. Hindmarsh (Newcastle), Mr. J. Collingwood Stewart (Newcastle).  
 Dr. O. W. Ogden (Newcastle), Dr. R. Ingram (Muswell Hill), Mr. A. Dewar (Stanley), Mr. C. W. Craig Dunlop (Carlisle), Mr. J. W. (Newcastle), Professor R. Hawden (Newcastle), Dr. A. Parkin (Newcastle), Dr. Howie (Newcastle), Dr. George Hall (Newcastle), Dr. D. Wells Patterson (Newcastle), Dr. R. W. Wardle (Newcastle), Dr. H. D. MacPhail (Newcastle), Dr. R. W. Wardle (Newcastle), Dr. W. Kerr Russell (Newcastle), Mr. H. Franking (Harrington), Dr. G. E. Lloyd (Hexham), Dr. C. C. N. V. Potts (Newcastle), Dr. C. Robertson (Darlington), Dr. C. C. R. Goodwin (Barrasford), Dr. P. Holgate (North Shields), Captain J. A. Charles (Stanley), Dr. A. Dryden (Newcastle), Dr. J. W. Gibson (Newcastle), Dr. W. Pattullo (Spenningmoor), Dr. W. Hudson (Bedlington), Dr. Langenberg (Houghton-le-Spring), Dr. A. Livingston (Newcastle).  
 £12.—Dr. H. Widdas (Shildon), Dr. P. Vernon Anderson (Shildon), Dr. Janet A. Vaughan (Kasimir), Dr. Hamilton (South Shields), Dr. B. A. Colville (Newbiggin), Dr. L. F. Brown (Felling), Dr. Whitley (Newcastle), Dr. H. S. Brown.

 Subscriptions Specified.—Dr. Sally Allen (Meadowfield), Drs. J. and G. Denholm

## Nova et Vetera.

### AN EARLY VICTORIAN MEDICAL JOURNAL.

PRACTICE and domestic medicine in 1837 were necessarily more primitive than now, but we should hardly have imagined them to be as nearly medicinal as appears from the perusal of an old medical magazine, of which the first number appeared in the year of Queen Victoria's accession. This journal is "The New Doctor, a Medical, Philosophical, and Literary Magazine, and Family Journal of Health: containing New Views in the Prevention and Treatment of All Disorders and Diseases familiarly described, and adapted to All Classes of Society." It was published with rude but spirited woodcuts by Steill of Paternoster Row, and the editor was G—S—, M.R.C.S., lecturer on midwifery and the diseases of women and children, author of a *Treatise on the Disorders of the Digestive Organs*, surgeon to two most respectable clinics, consulting surgeon to the St. John's Midwifery Institution, and honorary member of the Medical Society of St. Bartholomew's Hospital. This does not exhaust the catalogue of the New Doctor's qualifications, but it bears eloquent witness to his respectability in the profession. And this, from the modern point of view, is the more remarkable, for he is emphatically what would be now regarded as an advertising quack: he sells pills and plaisters named after himself, and takes half-crown fees from patients whose ailments mostly require anonymity.

We suppress the surname of the New Doctor, since it still survives honourably in the provinces and has been known in both medical and lay literature. The fact that the New Doctor could apparently proceed in his methods unchallenged and unrebuked marks the extreme difference between the medical ethics of two epochs.

Almost the first article in the magazine we are considering—for the first item is a picture of a skeleton—bears the curious title "Sedative Effects of the Spider's Web." It is the case of "an intelligent young man (in private practice), who after consuming three quarts of brandy in thirty-six hours, fell into a state of temulent excitement, so excessive that he was incapable of keeping a recumbent or even a sitting posture for more than a minute, but paced his chamber with a ceaseless step for two days and nights." He was not delirious, says the record, but vehement in his hurried talk, and haunted by visionary monsters. After taking quantities of opium he felt no relief till the New Doctor, on the morning of the third day after the drinking bout, began to administer *fresh spider's web* in pills of five grains every hour. The patient found great relief, and cobweb, the New Doctor opines, is the sovran remedy in cases of alcoholic excess. Once famous as a febrifuge, especially in Latin countries, cobweb is not now found in pharmacopœias.

The New Doctor on the whole holds sensible views on alcoholic and other excess. He recognizes that ale is bad for invalids, and recommends weak gin and water as far more wholesome than strong ale. "A festive season is approaching; beware, readers, of the dire effects of overloading the stomach"—thus he ends a Christmas article.

The major diseases are still treated by the New Doctor in the traditional manner. Thus "an excellent receipt for consumption" is Dr. Babington's, consisting of "one drachm of compound tincture of camphor, a few drops of aniseed oil, and two ounces of infusion of roses." This draught, amounting to a cough mixture, is to be taken twice a day to ease cough and irritation. "Cancer quackery," as it is called, is condemned, but the views of cancer set forth by this old therapist show that the disease was then rarely diagnosed. Too often, manifest carcinoma was set down as scrofula. A case of Asiatic cholera among the New Doctor's near neighbours is described at some length. Water contamination is not suspected as a cause of the disease, which is fatal in this case, and the patient is allowed to drink many quarts of pump water. The water supply of London, which the householder drew from pumps in the street, did not incur suspicion till long afterwards. The New Doctor is quite nonplussed as to the origin of cholera. He observes that in the great epidemic of 1832 the staff of the Free Hospital in Greville

Street, "opened for cholera cases during its ravages in London," noticed that constipated patients did not recover. Constipation, then, he opines, must have something to do with cholera.

In one particular he just misses being a prophet. We quote here from his article entitled "Contagion communicated by Insects." "We are authorized," he says, "we think, to infer that infection, if not contagious, may be communicated by flies and other insects, and we are of opinion that this is one of the leading causes of the spread of destructive epidemics, such as plague, small-pox, and, perhaps, typhus fever." Mrs. Baillie, Diemerbrück, Francis Bacon, and Dr. Rush are quoted in support of his thesis.

"During the yellow fever in Philadelphia, in 1793, we are informed by the celebrated Dr. Rush, 'that a prodigious number of flies and mosquitoes were observed.' The year 1663," says professor Chapman, "which produced a pestilential fever amongst the settlers at Plymouth, New England, was also remarkable for swarms of large flies, filling the woods with their hum." The same author informs us, that "during the prevalence of a recent epidemic [malaria] in America, which continued for three seasons, mosquitoes abounded beyond all former example; and on its cessation scarcely one was to be seen." In some recent investigations, also, of the yellow fever, the black vomit was found, during the life of the patient, so filled with animalcules as to compose the chief part of it. Though the professor, however, states these facts, he will not admit that there is any foundation for the opinion which we have attempted to advocate; but he adduces no reason whatever, except that he considers it "a much more rational conclusion," that the unusual number of insects "is owing to the state" of things of which epidemics are the effect. This position we would at once grant; but we think it extremely probable that a number of flies, mosquitoes, or other insects, after alighting on a deceased or dead body, and afterwards alighting on a person in good health, may infect the latter.

"We should like much to see this matter farther investigated by those who have more learning and more time than we can bring to bear on the inquiry."

Among disease-conveying insects the New Doctor expressly ranks "animalcules," which, he avers, are found in vast quantities in stagnant water and, among other things, in infusions of oats, barley, and wheat. Here, indeed, we have a dim adumbration of bacteriology and Pasteurism! He foresees the possibilities of the microscope:

"The naked eye takes in from the elephant to the mite; but here commences a new order reserved only for the microscope, which comprehends from the mite, to those twenty-seven millions of times smaller; and this order cannot be yet said to be exhausted, if the microscope is not already arrived at its highest possible degree of perfection."

VICTOR G. PLARR, M.A.

### INTELLIGENCE TESTS AND INDUSTRY.

THE Industrial Fatigue Research Board, in collaboration with the National Institute of Industrial Psychology, has instituted an inquiry into vocational guidance. In the course of the investigation much use was made of "tests of intelligence," most of which have up to the present been designed on a linguistic or verbal basis—that is to say, the answers to the questions submitted are expressed by means of words. It has been represented, first, that such tests, valuable as they are, may sometimes weigh unduly in favour of those which have a special facility for verbal expression, and may fail to discover intelligence, valuable for many industrial occupations, in those who have a special difficulty in using or understanding words; and secondly, that since with all individuals it is desirable to measure intelligence by the most comprehensive means possible, a combination of linguistic and non-linguistic methods is probably preferable to the former alone.

Miss Frances Gaw has made an investigation into what is known as "performance tests," which are mainly the production of American psychologists, and which have been tried and found directly applicable to children in elementary schools under the London County Council. The results of her investigations are now published in a pamphlet.<sup>1</sup>

The history of the developments of these tests is followed by detailed descriptions. Some of the tests, such as the Porteus maze test, are well known, others are of more novel type. Most of them are on quite simple lines and require no more intelligence than the recognition of a

<sup>1</sup> Industrial Fatigue Research Board. *Performance Tests of Intelligence*. By Frances Gaw, B.A. London: H.M. Stationery Office. 1925. (Pp. 41. Price 2s. 6d. net.)

shape and the production of this shape by the building up of pieces cut into several parts, for the formation of cubes or triangles, or of fitting pieces into a ground-work to fill up a simple jig-saw puzzle. Instructions are given as to the way in which the observer should note the actual performance of the child, and of the method of scoring adopted. Uniformity of method and marking is essential if the results are to be of any comparative value. Calculating intelligence quotients is not the only use that can be made of the scores. It is sometimes desired to compare groups of subjects by means of a given test, as for example, 9-year boys with 9-year girls in the Porteus test; or to compare results from a given test within a single group, as, for instance, the range in the cube imitation test covered by 11-year-old boys. For either of these purposes it is sufficient to compare scores without reference to mental ages. It is noted that the differences between boys and girls in performance tests illustrate two of the sex differences in various intelligence tests found by Burt, Terman, and others—first, that while girls excel in a linguistic type of test, boys excel in a more perceptual sensorimotor type of test; and secondly, that girls usually excel in memory tests, boys in reasoning.

The President of the School Medical Officers' Group of the Society of Medical Officers of Health gave for his presidential address in October last an account of his experience with intelligence tests as an indication of the prospects of defective young persons.<sup>2</sup> The tests employed were the second edition of the Binet-Simon tests of 1911. A detailed account is given of the results of these tests when applied during school life and the subsequent careers of the children on leaving school.

Summing up the evidence obtained from this examination of 112 after-careers, he said that if a boy on discharge from the special school has an intelligence quotient of 50 or over, with an average annual gain of six months or more, if his character has been good, and if he has some manual ability, he will probably succeed even if his home conditions are poor and his physique below normal (unless there is actual disease of the heart, lungs, or nervous system or actual crippling deformity). He is still more likely to succeed if he can be allowed to leave at 14 years, suitable occupation having been found for him. If, however, he has already shown antisocial tendencies he will probably presently have to be placed in a residential institution, especially if these tendencies are encouraged by similar actions at home, the antisocial tendencies outbalancing all the other factors. . . . Out of 131 persons from whom this experience has been gained, . . . only 7 per cent. are earning enough to keep themselves, and 28 per cent. are earning on an average 9s. 8d. a week. . . . A very liberal estimate would place the number of those capable of maintaining themselves at . . . about 17 per cent.

With girls, however, the chances of remunerated employment are decidedly less, and the influence of the home greater whether by causing the girl to be unemployed in a good home or causing her to be sent to a residential institution from homes which are undesirable. Also, as far as the experience of this school shows, there is no chance of a girl obtaining remunerated employment if school attendance is enforced until she attains 16 years.

A less optimistic view would limit the number of those capable of maintaining themselves to the [7 per cent.] who are already earning enough to do so, and would expect that the remainder would become chargeable to the rates . . . either as inmates of institutions or workhouses . . . or by requiring outdoor relief.

Institutional treatment is said to be impossible on account of the expense and the lack of institutions, but as it seems that great expense must ultimately be incurred to support these persons at a time when they will be too old to do anything towards earning their living, would it not be better to urge as strongly as possible the necessity for the increase in the number of institutions, and that they should be organized . . . so that every inmate should perform an amount of profitable work proportionate to his ability and be thus kept happily employed and earning something towards the upkeep of the institution? Thus segregated, the mentally defective persons would be kept out of mischief, and the output of mentally defective children would be appreciably reduced.

Special schools would then become only the preliminary observation grounds, at which the children could be graded, measured against the time when they would be drafted into the residential institution.

<sup>2</sup>The Value of Intelligence Tests in the Prognosis of the Future of Mentally Defective Persons. By James W. Fraser. School Medical Officer, Hull, 1924.

## CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS.

THE third annual report of the Cassel Hospital for Functional Nervous Disorders at Swaylands, Kent, is, like its predecessors, of considerable interest and value, and serves in particular to draw attention to the fact that provision, such as this clinic supplies, for the treatment of mild mental cases meets a greatly felt need. The medical director, Dr. T. A. Ross, following the precedent of former years, gives the after-history of all those cases in which it was obtainable, for he believes that, while on the whole the after-report can be shrewdly guessed from the state on discharge, there are exceptions; and from the standpoint of scientific evidence, the longer the period of freedom from symptoms has lasted, the more is it likely that the methods of treatment adopted have been of real value.

The present report contains not only details of all the patients who passed through the hospital in the year 1923, together with the after-history of a large proportion of them, but also further reports on those who were under care during the years 1921 and 1922, whose subsequent histories have been kept up to date. These details are given in an appendix; in each instance the number of months between discharge and report is indicated. The cases are classified by Dr. Ross into various broad diagnostic groups: the first, which includes the largest proportion of cases, embraces the psychoneuroses; the second deals with drug addicts; the third with psychoses, which are mainly of the depressive type; the fourth with organic diseases; and the fifth with a few unclassified cases. An interesting feature of these tables is that they contain a further classification of the psychoneurotic cases according to the results obtained by treatment. The first table contains the patients who are now well or improved; the second, those who are not better but who are at work; the third, those who are improved but who do not admit that the improvement is due to treatment at Swaylands; and the fourth, those who are no better. Of the 144 patients discharged during 1923, 98 belonged to the psychoneurotic group; and of these, 11 were not heard from, 62 were classified in the first table, 3 in the second, 3 in the third, and 19 in the last. These results may be regarded as very satisfactory, especially as they are based upon the condition of the patients some months after discharge.

It is probably true to make the generalization that the psychoneurotic does not make such a clear and undoubted recovery as many psychotics who recover. Many of the latter give the impression that they are quite well and will keep well. The psychoneurotic, on the other hand, may greatly improve under the protected conditions of hospital life, but upon discharge, when he has again to meet the difficulties of domestic and social life, some of which may have been largely responsible for his breakdown, it is by no means unlikely that he will again fail to make a good adaptation. For this reason the treatment of these nervous cases must not merely consist of "a rest cure"; it must include a course of self-examination, a widening of the conscious outlook, and a frank facing of the realities of life. From the reference to the modes of treatment adopted made in the previous report we gather that the treatment given is along these lines, and probably that is why the after-history has been so satisfactory in a good proportion of the cases. Dr. Ross draws attention to the fact that since the hospital opened there has been a waiting list which has blocked admissions for periods of from at least six weeks to about three months. Indeed, but for the fact that many have been found to have made other arrangements when their turn for admission comes, the blocking would have been more serious than it has. Dr. Ross points out that while most psychoneurotic patients suffer from a chronic disorder, and for many the weeks of waiting are at worst only an annoyance, there are some who cannot wait without a serious aggravation of their symptoms; there are others who, if they do not come at once, cannot come at all: for example, school teachers, students, and the like, who must employ their vacation for this purpose, people whom one would be sorry to see give up their work. He goes on to show that the most obvious

way to effect a reduction of the waiting list is to keep the hospital strictly to that class of case for which it is intended. The report shows that a number of cases sent by practitioners turned out to be suffering from lesions of the nervous system, arteries, heart, and other miscellaneous organic diseases. The admission of such cases must cause much inconvenience and disappointment, and Dr. Ross devotes a considerable section of his report to an analysis of the signs and symptoms presented by those patients who were found to be the subjects of organic disease, in the hope that his observations may be of some help in differential diagnosis. It is mainly through improved diagnosis that the full use of the beds can be obtained, and Dr. Ross considers that the elimination of the psychotic cases is of the utmost importance also from this point of view. He proposes to defer the discussion of this subject to another occasion, but observes that for certain patients with psychotic depression the hospital provides a suitable environment, though it does not do so by any means for all who are sent in.

## England and Wales.

### HUGH OWEN THOMAS MEMORIAL LECTURE.

DURING the war the council of the Liverpool Medical Institution resolved to establish a fund to keep green the memory of Hugh Owen Thomas, truly described as a surgical genius. Subscriptions came from surgeons the world over, and the council of the institution decided to establish a lecture on some surgical aspect of orthopaedics, to be delivered every two years by some eminent surgeon, and to use the interest of the fund for his honorarium. The second biennial lecture was delivered by Dr. Robert B. Osgood, of Boston, U.S.A., at the institution on June 2nd. There was a large audience, and the president, Mr. R. C. Dun, who was in the chair, introduced the lecturer in graceful terms. At the outset Dr. Osgood paid a tribute to the memory of Hugh Owen Thomas, and referred to Sir Robert Jones as a leader in orthopaedic surgery. Dr. Osgood took as the subject of his lecture the orthopaedic aspects of chronic arthritis. We hope to publish a report of the lecture in a subsequent issue. The lecture was listened to with attention and was much applauded. The president, in thanking Dr. Osgood, alluded to his inspiring qualities as a teacher.

### UNIVERSITY OF LIVERPOOL.

At the graduation ceremony held in St. George's Hall on June 5th, the Chancellor, Lord Derby, conferred the honorary degree LL.D. on Sir Dyce Duckworth, Bt., and on Sir Robert Jones, K.B.E. Sir Dyce was described as a distinguished alumnus of the old Liverpool Royal Infirmary School of Medicine, whose loyalty to Liverpool and his old school has been steadfast. A lover of books, a lucid teacher, a polished speaker, a writer who has advanced clinical medicine, the Chancellor expressed his pleasure as a Lancashire man on paying Sir Dyce the highest honour the University could bestow. Sir Robert Jones, who was greeted with vociferous applause by the students, was introduced as the greatest bone surgeon of this or any generation, renowned and honoured the world over. Through his influence and teaching he had been the means of saving to the Empire and the Allies a vast number of lives, and it was owing largely to him that our streets show relatively so few cripples as compared with bygone days. The Chancellor recalled the fact that as War Minister he had appointed Sir Robert to the Medical Advisory Board of the War Office. The illustrious surgeon had not kept his great skill and knowledge for Liverpool only, but had given them to the world at large. The University delighted to pay Sir Robert this high honour as a tribute to his outstanding ability in his profession.

### PRESENTATION TO DR. W. E. THOMAS.

Dr. W. E. Thomas, J.P., of Ystrad-Rhondda, was presented, on June 6th, by the insurance practitioners of Glamorgan, with his full-size portrait in oils, painted by

Miss Margaret Lindsay Williams, as a tribute to the great services he has rendered to the medical profession, and to the British Medical Association, of whose Council he has long been a member. A diamond brooch was given to Mrs. Thomas on the same occasion. The chairman of the presentation committee, Dr. J. Morgan Rees, laid stress on the great value of the yeoman service rendered by Dr. Thomas, not only to the medical profession, but also to the social and public life of South Wales and Great Britain. Dr. Howard Davies emphasized the courageous way in which Dr. Thomas had tackled so many difficulties in the past; and the Medical Secretary of the British Medical Association, Dr. Cox, speaking in the same strain, added that, in addition to his other qualities, Dr. Thomas had the very rare power of inspiring affection wherever he went. Dr. Thomas, replying, said that during the forty years he had lived in the Rhondda he had found that the people there proved to be very good friends. It was owing to the great self-sacrifice of his wife that he had been able to devote so much time to public work. Dr. Thomas was the guest of honour at a banquet which was held the same evening, when the toast of "The British Medical Association" was proposed by Sir David Evans, and the toast of "Our guest, W. E. Thomas, doctor of medicine, justice of the peace, and prospective high sheriff of his native county," was proposed by Sir Ewen Maclean. Dr. Thomas, in his reply, expressed his gratitude for the warm appreciation of his work. He was glad that his friends and colleagues had deemed him worthy of such a present in spite of the fact that he had never concealed or been false to his political or professional views.

### PUBLIC HEALTH NEEDS OF LONDON.

The Minister of Health, the Right Hon. Neville Chamberlain, M.P., received on June 8th a deputation from the London County Council, which submitted to him the report of the Special Committee on Health Administration in London. In submitting it, Captain C. E. Warburg, chairman of the Council, laid special emphasis on—

- (1) The necessity for an early reform of the Poor Law, along the general lines of the report of the Maclean Committee, in order that a fuller use might be made of the existing Poor Law institutions in the treatment of disease. Pending a settlement of the future of Poor Law infirmaries, it was not possible to reach a satisfactory position as to the hospital needs of London and, in particular, as to the use which might be made of the existing infirmaries in connexion with advanced cases of tuberculosis.
- (2) The need for the revision and consolidation of the Acts relating to health services in London.
- (3) The desirability of an expert inquiry into the question of the disposal of refuse.
- (4) The advisability of a technical inquiry into the problem of dealing with the drainage of London. This arose particularly in connexion with the pollution of the River Lea. One obvious solution of the problem was that the drainage of the outlying districts at present discharging into the Lea should be taken by the London County Council, but the capacity of the Council's sewers was limited, and the Council also felt that it should not lightly add to the volume of effluent discharged into the River Thames.
- (5) The desirability of instituting an inquiry into the after-care of tuberculous patients. Valuable as were the experiments being carried out at Papworth and Preston Hall, they could never by themselves provide a solution of the problem of tuberculosis in urban districts. Patients who returned from sanatoriums partially restored to health were in danger of relapse when they came back to the conditions of life in which they had originally contracted the disease, with weakened physique and earning capacity.

Mr. Herbert Morrison said that Labour members of the Council gladly endorsed this report so far as it went. They attached particular importance to the reform of the Poor Law, which had been promised for the last five years but had never made any progress. The Labour members did not, however, endorse the view that management by joint committees would be satisfactory; the alternatives were local administration pure and simple, or central administration.

Smoke knew no borough boundaries, and he was satisfied that the responsibility for dealing with smoke abatement should be laid primarily on the central authority for London. Mr. H. Arthur Baker, J.P., speaking for the Progressives, said that they warmly endorsed the report.

The Minister said that he welcomed the description of the relation between the Ministry, the London County Council, and the metropolitan borough councils as a partnership. He was satisfied that great value had been derived in the past from the surveys that had been jointly undertaken by the Council and by his department. The latter he regarded in the light of a sort of general staff in dealing with health matters. The Ministry of Health, ever since its foundation, had always been hampered by the demands made on the attention of Ministers by the housing problem, but this was only temporary and partial, and was now, he hoped, well on its way to settlement. He had already publicly announced his intention of dealing with the reform of the Poor Law next year, provided always that he was successful in getting the Rating and Valuation Bill, which was an essential preliminary, through the House of Commons this year. He agreed with the deputations that in dealing with advanced cases of tuberculosis it was highly undesirable to segregate them in special institutions, to be sent to which was regarded by the patients as equivalent to a sentence of death, but he was not yet satisfied that the existing Poor Law infirmaries were necessarily the best suited for that purpose. He agreed that in connexion with hospital provision, both for tuberculosis and other diseases, some central co-ordinating authority was necessary. This was a subject which would require further discussion. He had included a bill for smoke abatement in his programme for next year, but he was not clear that the view of the London County Council with regard to the advantages of central control in this matter represented the views of the majority, but he would give this point further consideration.

The consolidation of the Public Health Acts was in hand, though it would be necessary for him to pass a further amending bill next year before consolidation could be carried through.

He was inclined to fall in with the suggestion of an expert inquiry into refuse disposal, with a view to the issue of an authoritative technical report, though more information on this subject was already available than was generally made use of. Further consultation with the interests concerned, such as the metropolitan borough councils, would be necessary before he could set up the committee.

The drainage of London was rather a question for the London County Council itself to consider. It was clear that not much more sewage could be taken from outside districts without either enlarging the sewers or undertaking expensive works for the treatment of sewage, or possibly both. Either alternative would be very expensive. If the Council agreed he would gladly associate a technical officer of his department in an inquiry, and he thought that there should also be representatives of other authorities.

The after-care of tuberculous patients he regarded as an essential part of schemes for the treatment of the disease. If relapses of patients whose condition had been relieved were to be avoided suitable occupation under medical supervision was absolutely essential. Papworth and Preston Hall were useful examples of what could be done along these lines, but he agreed with the Council in thinking that they did not provide the solution of the problem so far as it affected the urban population. He had under consideration measures for increasing the after-care provision available.

#### THE LONDON HOSPITAL.

At the recent quarterly court of the Governors of the London Hospital Lord Knutsford announced that Mr. Bernhard Baron had presented £10,000 to the hospital for the erection of a pathological institute. The cost of the new operating theatre presented by Lord Bearsted would be about £7,000, and the donor desired that the difference between this cost and his gift of £10,000 should be invested so that the interest on the sum might be devoted to

medical research. A new hostel for the resident medical staff was to be built at the cost of £39,983; the children's department was to be enlarged and improved so as to serve as a consultative centre for all the child welfare organizations in the East of London. The honorary medical staff would be increased by the addition of a specialist in children's diseases.

#### UNIVERSITY COLLEGE, READING.

It is probable that University College, Reading, will soon become an independent university, the Privy Council having issued a notification that it would be prepared to recommend the grant of a Royal Charter subject to certain financial conditions. The College was founded thirty-three years ago in part of the old Abbey of Reading, from which it was transferred in 1804-5 to its present site. In 1896 the College Hall (seating 1,000 people) was opened, and in 1911 it was decided to apply for the status of a university, an endowment of £200,000 being in hand at this time. This application was delayed by the war, but after the armistice the recovery of the College was rapid, and in June, 1920, it was decided to proceed with the application for a university charter. The reply to the petition, while approving in principle the establishment of a university at Reading, required that there should be an increase in the number of students reading for university degrees, and that the College income should approximate £80,000. The present College income, apart from the halls of residence, has now reached this figure; including that from the halls it is more than £120,000. The first of these six halls was founded in 1805, and in 1808 the late Lady Wantage endowed a residential hall for men; soon afterwards an existing women's hostel was transferred to St. Andrew's Hall. The Faculties of Letters and Science are the foundation of the teaching, and there has been added a Faculty of Agriculture and Horticulture, including the British Dairy Institute and the Research Institute in Dairying. Supplementary faculties include the three schools of fine arts, music, and domestic subjects. The main site of the College building occupies about ten acres, interspersed with lawns and gardens. The residential halls are all within walking distance of the College, which owns about 530 acres of land.

## Scotland.

#### EDINBURGH POST-GRADUATE COURSES.

THE programme of the vacation courses conducted by a Committee of the University and School of Medicine of the Royal Colleges at Edinburgh has been issued. The courses begin on July 13th with one on obstetrics and gynaecology lasting four weeks. It includes daily clinics on midwifery at the Maternity Hospital, followed each day by clinics on gynaecology in the gynaecological wards of the Royal Infirmary. In the afternoon there will be ante-natal clinics, lecture demonstrations on obstetrical and gynaecological pathology and on infant feeding and ophthalmia neonatorum. Concurrently with this course another will be held upon diseases of children in the Royal Hospital for Sick Children. It will include medical clinics, surgical clinics, and clinics on ear and throat diseases, eye diseases, nutrition, child welfare, venereal diseases, and dentistry. From August 10th to September 5th there will be a general medical and a general surgical course. The medical course will include demonstrations on applied anatomy, a series of clinics in which the examination of the different systems will be taken up in rotation—the respiratory system, ductless glands, renal and alimentary systems, nervous system, and circulatory system respectively; a number of clinics upon dermatology, venereal diseases, diseases of children, diseases of the eye, and diseases of the blood. A few meetings are devoted to morbid anatomy, dietetics, genetics, comparative pathology, radiology, hydrology, and tuberculosis. The surgical course will include demonstrations on applied anatomy, general surgery, diagnosis of renal disease, and surgical pathology. Surgical and gynaecological operations in the Royal Infirmary and

Royal Hospital for Sick Children and a series of meetings and special lectures are open to those attending both the medical course and the surgical course. During the period of the general courses in August and September special classes will be held upon vaccine therapy, medical chemistry, and diseases of the blood, while at an earlier period of the summer courses will be available upon tuberculosis, clinical therapeutics, insulin therapy, venereal diseases, surgical pathology, diseases of the nose, ear, and larynx, ophthalmoscopy, and radiology. For each of the last-named classes a special fee is payable, while the courses on diseases of children, obstetrics, and the general medical and general surgical courses are covered in each case by a composite fee. Further information can be had on application to the Secretary, Post-Graduate Courses in Medicine, New University Buildings, Edinburgh.

#### MAN'S EVOLUTION.

Sir Arthur Keith took as his subject for the eighth Munro Lecture given in the Anatomy Theatre of Edinburgh University, "Australian aborigines, ancient and modern." All that was known of the early peoples of Europe had been derived from the study of fossil bones and of stone implements; but in Australia the anthropologist could still study living types of "fossil man." The Australian aborigine still retained a primitive mode of living. He neither sowed nor reaped, but was dependent on the natural produce of the soil and on his prowess as a hunter, just as were the inhabitants of Western Europe until some eight thousand years ago. In his body, also, the Australian aborigine was of a primitive type, and he might serve as a common ancestor of living types of Caucasian, Mongolian, and Negroid, but he had retained more than they the characters of the common ancestor from which all living races had arisen. Sir Arthur Keith discussed the possibility that a band of humanity had broken away from the ancestral stem at the dawn of the modern racial differentiation, and had somehow succeeded in reaching Australia. A discovery made in Australia eleven years ago made it reasonable to believe that the aborigine reached that continent long before the Ice Age had come to an end in Europe, although it was certain that Australia had been isolated by sea from the rest of the earth for many geological ages. This discovery was announced to the British Association in 1914 by Sir T. Edgeworth David and Professor J. T. Wilson, who had produced a fossilized human skull which had become exposed on the bank of a stream at Talgai in Queensland. These observers showed that this Talgai skull was in the same state of fossilization as extinct kinds of pouched mammals, which occurred abundantly in a stratum in the neighbourhood of Talgai. The discovery of the Talgai skull proved that man reached Australia and saw alive certain types of marsupial animals which were known to geologists only by fossil bones; the evidence made it appear that the Talgai man equalled in antiquity the Neanderthal man in Europe. In only one respect did the fossil skull differ markedly from modern aboriginal skulls, and that was in the size of the jaws. Never before had a human skull been seen with such a width of muzzle, while the roof of the mouth was shaped as in anthropoid apes, but the canine teeth were not prominent and pointed as they were in these animals and also in Pittdown man. The same process of jaw reduction had taken place in the development of the Australian aborigine as was seen in that of the Caucasian inhabitants of Europe. Sir Arthur Keith, however, did not think that this was to be explained as the result of eating soft and easily masticated food, for some races were much more liable to jaw reduction and jaw deformity than others eating the same kind of food. The people of the North-West of Europe, for example, particularly the Scottish people, were much more liable to irregular growth of jaw than the Southern races of Europe. The land bridge by which the ancestral people reached Australia was represented now by the Malay Peninsula, Sumatra, and Java, but the original Australian aborigine must have crossed a stretch of sea some twenty miles in width, taking with him his wife and his dog, from which the Australian dingo was descended, although it

clearly hailed originally from Asia. Representatives of the early Australian human stock were to be looked for in India and in the Malayan parts of Asia. The Mongols had generally wiped out all traces of this stock, but in certain jungle tribes of Southern India individuals could still be recognized with a definite resemblance to the Australian aborigine. The first colonization of Australia had, therefore, taken place from Asia at a time when our forefathers in Europe were scrambling for a living on the edge of the ice sheet. Tasmania stood to Australia as that continent stood to the rest of the world. The early Tasmanians were now extinct, but their stone implements were of a kind used by Europeans at a very early stage of evolution. The Tasmanian had had more of the negro in his composition than the modern Australian black now has.

In the ninth lecture Sir Arthur Keith dealt with the discovery of the real missing link. He believed that the discoveries of fossil man which had been made in Java by Dr. Eugène Dubois, Professor of Geology in the University of Amsterdam, had been of the greatest importance in reference to Darwin's theory regarding man's origin. Many missing links had been discovered in the chain which leads from ape to man. There were now only three kinds of great anthropoid apes—the gorilla and chimpanzee in Africa, and the orang in Borneo and Sumatra; but fossil fragments of at least twelve extinct kinds of great anthropoids had been found in Europe and India. All of these were "missing links" in the sense that they connected together the living types of anthropoid apes and showed what an immense family of these there had been in long past times; but none of these seemed to take us appreciably nearer to man than did the living gorilla or chimpanzee. At the human end of the scale, however, the case was quite different, for the fossil remains of Europe, Africa, and Australia carried the human lineage a decided step backwards towards an anthropoid stage, although between the lowest fossil man and the highest anthropoid there was still a wide gap. The fossil form found by Dr. Dubois in Java in the early nineties of last century had fitted into the middle of this gap and it had received the expressive name of *Pithecanthropus*. Of the Java man the skull cap, teeth, and thigh-bone had been found. The streams of Java made a record of history just as did those of Europe, and in their deposits were wrapped up the bones of the animals that lived on or near their banks. The fossil animals which had been found near the bones of the Java man were those found in deposits of India of late Pliocene date.

In the tenth and last lecture of the series Sir Arthur Keith gave a summary of the origin of the "Nordic type"—that is, the kind of man who made up the backbone of the population of North-West Europe, including the British Isles. Fifty years ago anthropologists had spoken of Celts and Saxons, and had held that the British people was an imperfect amalgamation of these two races. The politician still retained these terms, which he rightly believed stood for realities of race, but the scientific anthropologist had had to abandon the idea of race, and only spoke of types. Amongst modern Europeans three main types were to be distinguished: the "Nordic type," which was tall, fair, long-headed, and usually long-faced, and formed the ancestral types of the peoples of Britain; the "Mediterranean type," which had had its home since remote times in the South of Europe; and the "Alpine type," distinguished from the other two chiefly by the rounded shape of his skull. The Nordic type was a development of the Caucasian stock which had ousted Neanderthal man about 20,000 years ago. The earliest known representatives of the Nordic race were two skeletons found in sand deposits on the Rhine opposite Bonn, one a man and the other a woman. Both had been buried with tools and ornaments used by reindeer hunters in the final phase of the Ice Age, the bodies had been sprinkled thickly with red ochre and interred with ceremony, and they dated from a period some 12,000 or 14,000 years ago. While the male skull had strong jaws, wide cheek arches, and heavy eyebrow ridges, the woman's skull had been like that of her modern representatives. This structural difference between the sexes had been

exaggerated in all of the early European pioneers, among whom the woman seemed always to be ahead of the man in evolutionary progress. At a much later date traces of early Nordic people had been found in the Baltic lands and in Scotland, but though their stone implements and bone harpoons were known the very early burials of these Nordic people north of the Humber had not yet been found.

#### SCIENCE AND HEREDITY.

A lecture upon the inheritance of acquired characters was delivered on June 4th by Dr. F. A. E. Crew, lecturer on genetics in the University of Edinburgh, under the auspices of the Workers' Educational Association. Professor N. Kemp Smith presided. The lecturer said that a character might be either genetic in its origin (that was to say, associated with a hereditary mechanism) or it might be produced by environment (that is, due to the impression on a plastic body of a change in use or in surrounding influences). It was, he considered, established beyond doubt that every character based upon determiners in the germ plasma was hereditary, and the mode of its inheritance could be predicted. It was also established that any character that had no basis in the germ plasma was not inherited. There was no doubt, however, that the effects of use and disuse, as well as of external changes, led to profound modifications in structure, form, and function. The question at issue was whether or not the latter agencies could affect the germ cells of an individual in a permanent manner. It was known that alterations in the germ plasma were not uncommon, and that having taken place such an alteration persisted, but the causes producing them and the manner in which they occurred had not yet been discovered. It was possible to affect the germ plasma by subjecting it to the action of alcohol or x rays, but such methods were similar to dissecting a flower with a charge of nitroglycerin. As technique improved, however, more localized and delicate interference with the ordinary processes of hereditary transmission might be expected. At present such evidence as existed seemed to lead to the conclusion that acquired characters were not transmitted in inheritance, and that it was not, therefore, reasonable to base any line of action in sociology or education on the assumption that they were.

#### FORTHCOMING CONGRESSES IN EDINBURGH.

The Inter-State Post-Graduate Assembly of America, which is at present visiting various medical schools in England, will pay a visit to Edinburgh on June 18th, 19th, and 20th. The members of the Assembly will be received on June 18th by the Vice-Chancellor of the University in the McEwan Hall, where the honorary degree of LL.D. will be conferred upon Dr. Charles Mayo of the Rochester Clinic, Minn. On the evening of the same day the Lord Provost and magistrates will hold a reception for the members of the Assembly in the Royal Botanic Gardens. The greater part of Thursday and Friday and the morning of Saturday will be spent in the Royal Infirmary, where operations and ward clinics are to be conducted by members of the staff in the forenoons and a series of "dry clinics" delivered in the afternoons. A museum of surgery, pathology, and tropical diseases is being arranged in the Pathological Department of the Royal Infirmary. Arrangements are being made for a visit to Holyrood Palace on Friday, June 19th.

The Congress of the Royal Sanitary Institute opens in Edinburgh on July 20th, and will, it is expected, be attended by between 1,200 and 1,500 delegates and members. The Congress is the thirty-sixth of the series, will last for five days, and will be attended by visitors from almost every country in the world. The Secretary for Scotland, Sir John Gilmour, will deliver an inaugural address on the opening day of the Congress. The meetings will be held in the University of Edinburgh, and visits have been arranged to various health institutions and to places of historical interest in and around Edinburgh. The Health Exhibition, to be held in the Waverley Market, will be an important feature of the Congress.

## Ireland.

#### VACCINATION IN THE FREE STATE.

IN a recent discussion in the Dail with regard to the Ministry of Local Government urging local authorities to prosecute in the case of vaccination defaulters, Deputy Sears said that the Minister of Local Government should amend the Irish law so that it would be on the same basis as the English law. Parents in Ireland to-day were bound by the law to vaccinate their children. In Wexford, however, two or three out of every four children were not vaccinated, and Wexford was as healthy as any other county in Ireland. The statistics compiled applied to deaths from measles, scarlatina, and other dirt diseases, and deaths from these causes had fallen considerably. Vaccination or other such treatment could not claim the credit of that decline. The same causes that had brought about the decline in measles and scarlatina brought about a decline in small-pox. The decline was due to improved sanitation and improved housing. Those things had brought about a better state of health in the country. Sir James Craig, M.D. (Dublin University), observed that on a previous occasion Deputy Sears had said that the profession was tired and needed a little amusement, and that the only way they could get amusement was by going around with their instruments and inserting dirty lymph in the arms of children. Deputy Sears did not go so far that evening, but he made statements which it should not be necessary for him to repeat, but, from the attitude of the Dail, he took it that members would like him to reply. It was true that in England there had of recent years been epidemics of small-pox, but Deputy Sears was wrong in his conclusions, because statistics showed clearly that small-pox attacked unvaccinated populations, and where it did attack the vaccinated populations it attacked them in a mild way, and these were cases where revaccination had not been done within seven or ten years previously. Deputy Sears made a statement which ought to be repelled—namely, that the calf lymph used in vaccination was impure. He was surprised to have to refute such a statement. The Government had under its control an institution in which the calf lymph was prepared in the most hygienic surroundings and under the supervision of a most experienced bacteriologist, so that there was a guarantee that all the lymph distributed throughout the country for vaccination was absolutely pure. He would go so far with Deputy Sears as to say that in the old days when lymph was inoculated from arm to arm there was a certain risk of inoculating syphilis from one arm into another, and there was a danger of inoculating other blood diseases. That had entirely passed away with the pure calf lymph which was now being used for vaccination. He would venture the opinion that the reason why the people of Wexford had not allowed their children to be vaccinated was because they had been led astray by cranks. He did not for a moment admit that measles and scarlatina were dirt diseases. If they were dirt diseases they could have been eliminated altogether.

#### PREVENTIVE AND CURATIVE MEDICINE IN THE FREE STATE.

Dr. T. Hennessy (Dublin City South), Irish Secretary of the British Medical Association, speaking recently in the Dail on the vote for the office of the Minister of Local Government and Public Health, said that in the administration of medical matters there were grave defects, both centrally and locally. He did not desire to attribute these defects altogether to the present Minister of Local Government and Public Health, who had made very considerable advances, especially on the preventive side. Any marked improvement in the general health of children would be brought about by good housing combined with proper and sufficient feeding. The present high mortality amongst Dublin children was due to insanitary housing and the want of sufficient and suitable food. Recent public health legislation had been on a comprehensive and generally on an up-to-date basis. The Dairy Produce Act was excellent in its conception, and would, he had no doubt, achieve at the butter factories everything for which it was intended, but to get

the full value out of this Act it would require a more rigid administration of the Inspection of Cowsheds and Dairies Acts, and he would suggest the employment of the Civic Guards, as otherwise the administrative cost would be prohibitive. He would also suggest that the Minister of Local Government and Public Health should see that the county medical officers of health to be appointed next October should receive an adequate salary with sufficient allowances for travelling expenses; if these officers were underpaid their activity could not be assured and they might as well not be appointed. The curative side of medicine in the Free State, although progressing, still had arrears to make up. The abolition of the office of medical commissioner in the Ministry of Local Government and Public Health was a distinct disadvantage; the medical profession did not, either in an official or advisory capacity, occupy the position which in the public interests it merited. The little importance the public seemed to attach to the amount of work which was done by the dispensary doctors was surprising. The returns for the Free State showed that 483,270 new cases were treated in 1923. More than a fourth of these were treated at the patients' homes. Owing to the reluctance and neglect of patients to produce tickets for medical treatment, the figures given would be nearer the true number if multiplied by three; this was true especially of patients who attended the dispensaries. For all this work the dispensary doctors received a total sum of £150,000 a year, which was very much less, at garage rates, than the mileage covered in attending the domiciliary cases. The Minister for Local Government and Public Health said that Dr. Hennessy's speech, whilst in some respects praising the Ministry, contained on the whole serious criticisms of its work. Dr. Hennessy seemed to think things would be better if there was a Ministry of Health and if the medical profession occupied a more prominent position in the Ministry. In 1904 the average salary of a dispensary doctor was £109 a year; it was now £251. Dr. Hennessy had inquired what the salaries of the new county medical officers of health would be. At present he (the Minister) was not in a position to state what the salaries would be, but he should say that they would be up to £700 a year, or perhaps more. He agreed with most of what Dr. Hennessy said in regard to the supervision of milking, but he believed the appointment of the county medical officers of health would remedy the matter. Moreover, the Ministry intended to appoint county veterinary surgeons to supervise all matters under the Dairies and Cowsheds Orders. He believed in vaccination, and he was convinced that its neglect in England was responsible for the recent outbreaks.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### The Finance Bill.

THE House of Commons resumed its sittings on June 9th, and discussed the Finance Bill in Committee on that and the following day. On June 11th it debated a Government proposal to impose a duty on imported lace. The Finance Bill will be further debated next week.

### "Patent" Medicines.

During the consideration of the Finance Bill on June 9th debate arose on Clause 2, which provides that the additional excise duties imposed by Section 11 of the Finance (No. 2) Act of 1915 upon medicines liable to duty should continue to be charged until August 1st, 1926. Mr. Wedgwood Benn complained of the manner in which this clause was drawn. It referred to the Finance Act of 1915, which in turn referred back to the Medicine Stamps Act of 1802, and that measure related to the Tonnage and Poundage Act of Charles II. The Act of 1802 set out a schedule of medicines liable to be taxed, which included Austin's chalybeate pills, Addison's reanimating European balsam, Clyde balsam, Guest's welcome guest powder, and Wheatley's ointment and fluid. An Act of 1812 revised the schedule, and that was the last revision he could find. He asked if it would be possible to include in the next Finance Bill a clause stating plainly what the taxes were and on what commodities they were levied.

Mr. Guinness (Secretary to the Treasury) said that the first legislation on this subject was passed in 1783. Since then there had been repeated amendments. He admitted that it was not

very easy to summarize the principles on which the duties were imposed. Speaking generally, there were three alternative tests of whether a preparation was liable to duty. The first test was that it must be advertised, or, in other words, recommended as a specific for some illness or disease. If it was said that So-and-so's preparation cured headache it was liable to duty, but if it was said that such and such an ointment was good for the skin it was not liable. The second test was that the remedy should be secret, and the third that it should be proprietary. The proprietary test covered most of the preparations that came under the old Patent Medicines Duties. He would like to look into the codification of legislation on the subject, but that was a matter which concerned the Ministry of Health rather than the Treasury. A few years ago a Select Committee inquired into the subject, but nothing had been done as a result of its report. There were many more complicated forms of revenue collection, which were based upon a far more scattered legislative code than this particular duty. In view of the fact that it was working smoothly, he did not think the House would see any cause to resist the retention of this clause. The duty was doubled in 1915 as a war tax, and was now yielding over £1,300,000, which was nearly three and a half times as much as before it was increased. That showed that the tax was useful from a revenue point of view, and it was not pressing hardly on any section of the population.

Sir Alfred Mond said the matter had nothing to do with the Ministry of Health. If the recommendations of the Committee were adopted it would be necessary entirely to alter the process by which these duties were levied. A large number of American "patent" medicines or mixtures were imported into this country. The importers of these foreign productions were given an advantage compared with those of British manufacture. He suggested that an expert committee should be set up to study the question.

Dr. Haden Guest said that the compositions of most of these patent remedies were perfectly well known and quite simple. Their vogue depended on the extent to which they were advertised. The law on the subject should be codified and brought up to date before the next Finance Bill was introduced. If the tax were reduced to a reasonable and intelligent code more attention might be paid to the demerits of some of these productions.

The clause was then accepted by the House.

**Operations on Children.**—Mr. Neville Chamberlain informed Colonel Day that statistics of the total number of deaths of children under 2 months old in workhouses and infirmaries were not available. In 1923 no infants under 2 months old died under or in connexion with the administration of an anaesthetic in a workhouse or workhouse infirmary in England and Wales. Colonel Day, in a supplementary question, asked whether the Minister of Health was aware that facilities had been granted by Westminster Hospital for the mothers of children to attend operations and to remain at the hospital so that they could feed their children at the breast. No answer was returned.

**Methylated Spirit Drinking.**—Mr. Guinness informed Commander Bellairs that he was not aware that the drinking of methylated spirits was on the increase. In the year ended March 31st, 1925, the quantity of mineralized methylated spirits sent out by makers in Great Britain and Northern Ireland was 1,383,448 bulk gallons.

**Subnormal Prisoners.**—In reply to Mr. Rennie Smith, the Home Secretary said male prisoners who, although not certifiable as insane or mentally defective, were unfit for the ordinary discipline of a prison, were collected in four prisons; similar female prisoners in three prisons. Since July 1st, 1924, ninety-one males, seven under 21 years of age, had been transferred to these centres from other prisons. Four female prisoners were transferred, one under 21 years. All were serving sentences of three months' imprisonment or more. In addition there were at the centres fifty males and eighteen females of the same class. All such prisoners were under special supervision. Brabazon classes had been arranged for those who were unfit for ordinary prison work. The prisoners were under the observation of the medical officers and of a selected staff, and special allowance was made for the inability of the prisoners to conform to prison discipline. The prisoners received extra facilities for exercise.

### Notes in Brief.

The Admiralty is inquiring into the complaint that at the Royal Naval Hospital, Simonstown, South Africa, English ratings of the Royal Navy are accommodated in the same wards as Kroomen.

The Under Secretary of Health for Scotland states that where a pauper lunatic in Scotland has been removed to an asylum without the consent of the relatives, the parish council can still recover the expenditure on maintenance.

The reports of the district medical insurance officers for Edinburgh, Glasgow, Aberdeen, and Dundee will not be published in full, but a summary with extracts of special interest will be embodied in the annual report of the Scottish Board of Health for 1924.

The Government cannot promise legislation to compel the insertion in every book of the date of publication.

During the three months ended May 1st last 21,674 houses were completed in England and Wales in connexion with State-assisted schemes, and 56,202 were in course of construction on the date mentioned.

## Correspondence.

### RAW PANCREAS BY MOUTH COMPARED WITH INSULIN.

SIR,—May I, as a diabetic, enter the arena in the important discussion that has been going on in your columns on the above subject? On the one hand Dr. Hollins and his supporters find raw fresh pancreas by mouth entirely satisfactory in the treatment of diabetes, and on the other Drs. Harrison and Graham find it utterly useless. The question is of the utmost importance to all diabetics, and the following experiment, conducted on myself, shows that raw pancreas is quite ineffective in severe diabetes. The idea that it may be a substitute for insulin may quickly lead patients to disaster.

The diet for the past eighteen months has been 45 grams of carbohydrate, 80 of protein, and 150 of fat, and insulin varied from 34 to 22 units a day, depending on the variations in the strength of insulin and the amount of exercise taken. Blood sugars have varied between 0.14 to 0.20 fasting level and 0.08 to 0.12 per cent. three or four hours after insulin. Glycosuria has been entirely absent except for occasional traces after breakfast. Insulin was discontinued on the morning of May 27th, and the diet kept constant, except to replace a corresponding quantity of protein when raw pancreas was taken. Fresh raw frozen pancreas was obtained, by the courtesy of the British Drug Houses, in the same condition as the glands from which they obtain the maximum of insulin.

The blood sugar on May 27th was 0.190 per cent. before breakfast (20 grams of carbohydrate); one hour after breakfast 0.302; two hours 0.295; three hours 0.268; four hours 0.260; and the urine sugar varied from 4 to 6 per cent. One ounce of raw pancreas was taken before lunch (5 grams of carbohydrate). The blood sugar one and a half hours after lunch was 0.258 per cent.; three hours after 0.236; then one ounce of pancreas, and one and a half hours later the blood sugar was 0.244 per cent. One ounce of pancreas before dinner (20 grams of carbohydrate), and the blood sugar two hours later was 0.278 per cent. One ounce at bed time. Next morning the fasting level was 0.278 per cent., and one ounce of pancreas was taken. The blood sugar one hour after breakfast was 0.340 per cent., two hours 0.350, three hours 0.340, and thirst and polyuria were severe. Insulin 12 units was then given; the blood sugar one and a half hours later was 0.245 per cent.; then lunch as before; and four hours after insulin the blood sugar was 0.105 per cent. While insulin was omitted and pancreas taken, the ferric chloride test for diacetic acid became positive for the first time for months.

Besides proving conclusively that raw pancreas is no substitute for insulin, the above shows what happens in a severe case when insulin is omitted. During the first five hours far more glucose was excreted in the urine (63 grams) than was absorbed in the food (47 grams glucose equivalent). On the second day, 23 grams was excreted during one hour alone after breakfast. This occurs because the carbohydrate which insulin has stored in the body as glycogen in the liver, etc., cannot be maintained and immediately floods the blood and urine with glucose. Dr. Cammidge seems to suggest that raw pancreas may at least control this "glycogenetic" function, but the above experiment disproves this also.

Dr. Hollins admits that raw gland is ineffective in insulin cases, and is at a loss for an explanation. What happens is that insulin temporarily makes the diabetic metabolism normal and builds up a normal glycogen store which at once reappears as glucose when the patient has to rely on his deficient endogenous insulin. Dr. Hollins himself finds in these cases that raw pancreas is no substitute for insulin, and is only effective where no insulin has been used—that is, in mild cases, I suspect. If raw pancreas acts at all it ought to act when insulin is omitted, as there is no evidence that insulin changes the nature of diabetes or does more than control it temporarily.

On reading the arguments on both sides, we see that in carefully controlled cases on weighed and constant quantitative diets, raw pancreas is no substitute for insulin and has no effect on severe diabetes. On the other side we are told that a "strict diet" was observed, but are given no details and are not even assured that it was weighed. Dr. Dunn states that his patient could only tolerate "1½ oz. of starchy food." Is this in the twenty-four hours or at a single meal? Is it 1½ oz. of bread or cabbage, which contain respectively 22 and 1½ grams of starch? The control of diet is the difficult factor in experimental

work on human diabetes. One is often assured that a case is severe and has been on a strict diet and has not improved, while two or three days on a weighed diet renders the patient sugar-free and proves the mildness of the case. I do not suggest that the discrepant results obtained with raw pancreas depend entirely on such an obvious explanation, but the supporters, by giving no facts or figures, lay themselves open to this accusation. (I found raw pancreas so horrible as to prefer a dozen injections a day, if necessary, and I am sure that its continued use would have made me unable to eat much else—thus providing a simple method of introducing nausea, starvation, and under-nutrition into the treatment!)

Raw pancreas has been carefully tried before and found wanting. Though it cannot replace insulin, the slender possibility still remains that it may stimulate and cause the release of endogenous insulin in mild or moderate cases. I intend to try such cases in a carefully controlled experiment lasting two or three months, and, though I am not hopeful, I shall be delighted to find evidence of its value in treatment.

In the meantime some patients, who have not had it, are clamouring for raw pancreas. Give it to mild cases by all means, if they insist, in an experimental frame of mind, but do not court disaster by its use in severe cases.

—I am, etc.,

London, W.1, May 30th.

R. D. LAWRENCE.

### THE BLOOD PRESSURE IN SPLENOMEGALIC POLYCYTHAEMIA: A SUGGESTION.

SIR,—It is not yet sufficiently recognized that in true splenomegalic polycythemia (erythraemia, or the "Vaquez-Osler disease") the blood pressure is hardly ever more than slightly, if at all, above the average, in spite of the fact that, as measured outside the body, the blood viscosity is greatly increased. Some compensatory mechanism doubtless exists within the body to account for this. The mechanism in question is probably of autonomic nervous origin, and must, I think, depend on the reflex opening up of numerous blood capillaries, which would, under normal conditions, be closed or contracted. Active dilatation and contraction of capillaries play an important part in the regulation of the circulation—a part till recently hardly even thought of (cf. the investigations of Otfried Müller, Parrisius, and others with the skin microscope). Such a diffuse capillary dilatation in cases of splenomegalic polycythemia is proved at necropsies by the great engorgement of the viscera with blood, and during life it manifests itself by the redness (often with lividity) of the lips, nose, ears, tongue, fauces, and elsewhere.

The "Studies of capillaries and blood volume in polycythemia vera," by G. E. Brown and H. Z. Giffin, in the *American Journal of the Medical Sciences* (1923, cxlvi, pp. 489-502), intimately bear on this question, but the authors regard the (proved) dilatation of the blood capillaries as being rather compensatory for the increase in the total blood volume than for the increase of the blood viscosity.—I am, etc.,

London, W.1, May 30th.

F. PARKES WEBER.

### THE EARLY DIAGNOSIS OF CANCER.

SIR,—Some twelve months ago it was suggested that the education of the public on the signs and symptoms of cancer would cause them to seek immediate advice. This has since been advocated by numerous writers in both the lay and medical press. So far as my experience goes it has done little good and much harm. People still do not go to their doctor for a lump in the breast, as they dread an operation. In addition, cancer phobia is developing, the sufferers from which it is impossible to convince. Some of these resort to quacks, who profit by curing such "definite" cases of the disease. After all, this is what one must expect, as the normal person rarely bothers about a disease the flesh is heir to. It is usually the neurotic who reads articles on medical subjects, the constant perusal of which will sooner or later lead his imagination astray. Most medical men will remember the imaginary diseases of student days

that disappear after experience in practical medicine, which alone can give a real appreciation of the value of symptoms. Few lay people can ever attain to this. To try to frighten the easy-going healthy Britisher—and cancer seems to prefer the healthy man—is foredoomed to failure, showing as it does a want of knowledge of the ways of our people.

It is a mistake to think that the early diagnosis of cancer will take place from without rather than from within the profession. What is necessary is to impress on the public that a medical examination at least once a year, and certainly after the age of 40, is just as essential as an annual holiday. During this the doctor could, without alarming the patient, find out whether anything suggestive of cancer was present. But for such an examination to have any practical value we must have a profession that is thoroughly conversant not only with the earliest signs of the disease, but is also aware of valuable methods of diagnosis when certain suspicious symptoms exist.

Those of us who have the responsibility of teaching students realize the importance of laying stress upon these points. But our teaching can be of the greatest value only if we are supported by the examiners. For the aim of the average student is to qualify; and he most appreciates that teaching which enables him to get through his examination. Should he qualify, he usually has a respect for the views of his examiners, which he remembers for the rest of his life.

I am afraid that in our efforts to make our students practical men who are not supported by the examiners to the extent we might wish. I shall take as an example the question of haematuria. At the end of each lecture on the subject it is my custom to stress the following points:

Haematuria is a symptom and not a disease. Drugs have practically no action, and, being intermittent, it ceases whether treatment is carried out or not, no matter what the cause. As an apparently quite innocent variety of haematuria may be due to a cancer in the urinary tract, no medical man has the right to treat an undiagnosed case of haematuria, certainly after the age of 30, until a cystoscopy has been performed.

I do this with all the more zeal because in the last twelve cases of cancer of the bladder seen by me the average duration of the haematuria was two and a half years, and in only two was removal considered advisable. Yet some of our students tell me that at a recent final examination they were taken over the diagnosis of haematuria and stress was laid on the difference between that due to innocent and malignant growths of the bladder. The reply expected was that the bleeding of a papilloma is symptomless, that of a malignant growth is associated with frequent and painful micturition. Yet in practice one knows that in the earliest stages—and it is only here that the operative treatment of cancer is really worth while—there is no difference, and the diagnosis can be made only by cystoscopy. If our men who qualified remain impressed by the views of these examiners, then it is obvious that no improvement in the statistics of the operative treatment of cancer of the urinary tract can be expected.

Our knowledge of the early signs and symptoms of cancer might be abbreviated into about twenty rules. Were a knowledge of these, together with an acquaintance of the methods of investigation that are available, to be insisted on at all final examinations (in fact, the failure to answer one should be regarded as equivalent to a "plough"). Then men from the day they qualify would be impressed with the necessity of being on the lookout for them. And this, combined with an annual overhaul, the wisdom of which is beginning to be appreciated by the public, and to which they will soon consent, will enable the precancerous conditions to be recognized at the time they are most suitable for treatment. No neurosis or morbid fear is set up; and the doctor will be able to influence the patient should any growth be found. It would thus be possible to accomplish in a short time what all the propaganda of to-day can do only after the expenditure of much money and time, and without any of its harm.—I am, etc.,

Cardiff, June 4th.

T. E. HAMMOND, F.R.C.S.

## COELIOTOMY VERSUS LAPAROTOMY.

SIR,—In a memorandum on page 1006 of the issue of May 30th Mr. Muingot rightly uses the word "coeliotomy" to indicate a central abdominal incision, whereas in his heading "laparotomy" is used. I fear it is too late to impress on my colleagues that laparotomy is a misleading word; it designates an incision through the flank. (By the by, the word should be "laparatomy," the word for flank being *λαπάρα*, not *λαπαρό*). On the other hand, coeliotomy correctly indicates an abdominal incision; or, as old Dr. Robert Lee once called it, at a meeting of the Medico-Chirurgical Society in Berners Street, "belly-ripping." Bland-Sutton uses the correct term, but I do not know how many other surgeons do.—I am, etc.,

Chichester, June 3rd.

HAYWOOD SMITH.

## ULTRA-VIOLET LIGHT.

SIR,—I have read with surprise Mr. Percy Hall's letter in your issue of June 6th (p. 1061).

He raises certain points which provoke inquiry. Writing about the mercury vapour lamp, he says: "Its fragility and varying output render it unreliable," and later, "The tungsten arc lamp is as great an advance over the mercury vapour lamp as is the Coolidge tube over the old gas-filled tube in x-ray work—that is, for operators who desire to standardize their dosage and results." Using the mercury vapour lamp experimentally, I have found it extremely easy to control, very reliable in its output, which can be maintained perfectly steady, making it possible to repeat exposures with accuracy and always producing the same result provided the necessary standard conditions are kept constant.

Dealing with the tungsten lamp, he says, "The only variable factors—target skin distance, amperage, and exposure time—are under the control of the operator." Lower down on the same page we find this: "The personal factor or idiosyncrasy of the patient is of the utmost importance. No two patients react alike, and no patient reacts in the same manner to successive doses." There is no suggestion as to how this factor is taken into account in treatment.

In another paragraph Mr. Hall observes that—

"The skin reaction or erythema is nothing to go by. . . . I have given dozens of doses to infants and children without any skin reaction, and yet have achieved the results I desired. Similarly with pigmentation, which, more often than not, is what one wants to avoid. If pigmentation occurs too early further treatment is useless, as the pigment acts as an impervious screen to the ultra-violet rays."

It is interesting to compare the above statement with the following quotation from page 19 of Mr. Hall's book *Ultra-violet Rays in Treatment and Cure of Disease*:

"This reaction (pigmentation) has to be carefully watched. It is an excellent guide as to both progress and prognosis. The degree of pigmentation is proportionate to the gain in the patient's powers of resistance against disease, and, roughly speaking, corresponds to his rate of progress towards cure."

Perhaps I may be allowed to quote also from a paper I read before the Royal Society of Medicine on April 17th of this year:

"If pigmentation is aimed at as a standard of treatment this is tantamount to producing deliberately in the patient a natural and efficient protection against the very source of treatment employed. . . . If pigmentation could be avoided without preventing the penetration of the rays to the cutis vera it might prove more beneficial."

I should like to know what has led Mr. Hall to change his views between last year and last week; whether it is as a result of individual experiment, or as a result of work by others, and, if so, by whom.—I am, etc.,

P. REDINGTON PEACOCK,  
M.R.C.S., L.R.C.P. Lond.

London, W.1, June 8th.

## SEVERE DERMATITIS FOLLOWING ULTRA-VIOLET LIGHT.

SIR,—There are several points of interest in the paper by Drs. MacCormac and McCrea published in the *JOURNAL* of April 11th (p. 693). They do well to draw attention to the danger in the use of powerful remedial agents by untrained and inexperienced persons. It is to be hoped that

the lay press, which has recently made so much *rêclame* for the artificial sunlight treatment, will give this aspect of the question an equal amount of prominence.

Such prolonged exposure to the rays as that to which this patient was subjected is very rarely employed therapeutically. It must not be denied, however, that irradiations up to an hour have been used upon patients without any untoward effects. These long exposures have only been given after a period of treatment had elapsed. The time of exposure is gradually increased, and the distance of the lamp from the body is gradually diminished. It is my experience that after a time the patient's skin becomes accustomed to the rays.

Accidents of the nature described are rare. Your contributors do not state the distance that the lamp was from the skin in their case. Distance is an important factor, especially when one is dealing with the air-cooled mercury vapour lamp. It is remarkable how well even comparatively severe burns heal.

The ultra-violet rays have on an average a penetrating power of about 1/2 mm. It has been observed, however, that exposure to the rays has a powerful effect on the whole economy of the body. It has been suggested by Hoffman (*Deut. med. Woch.*, 1919) that the skin performs a biological function—"Esophylaxie." In virtue of this view it is possible that the reaction of the skin of the back in Drs. MacCormac and McCrea's patient was in the nature of a defence reaction.—I am, etc.,

Johannesburg, May 7th.

M. LIRSCHITZ, M.D.

#### THE GENERAL PRACTITIONER.

SIR,—It has been left for our wise visitor Dr. Charles Mayo to voice the need of more of the ordinary common variety of doctor, "someone who can take care of people when they are sick." In one illuminating phrase he defines the field of general practice, and indicates its proper and peculiar function. Human nature sick demands something more than a book of rules of health, and this touch of nature it is the birthright of the ordinary doctor to give. No bureaucratic infiltration, no net of regulations, can dilute his efforts or hamper his steps in this the ultimate sphere of his life's work. But he must be worthy of the trust, and so silence the voices raised against him.

Dr. Mayo expresses the view that the next twenty years will see a relative increase in the number of general practitioners. The conditions of practice were never more burdensome than they are to-day. Modern developments have added materially to the weight of uncompensated work, and have immeasurably increased the wear and tear on mind and body. The practitioner is more accessible, more often consulted for minor ailments, more apt to have his time devoured by "the beginnings of disease" (often a mare's nest, alas!), more under the necessity of facing, guiding, and enduring that half-knowledge which is worse than ignorance. Yet his early training fits him for none of these things. The student sees our mistakes and knows nothing of our trials; his attitude towards the general practitioner is entirely uninstructed, though the majority must needs put on the ordinary doctor's mantle.

There is neither any sign that the burden of practice in the future will be lightened nor that the rewards will be greater. What inducements, then, can this field of work offer? An answer will have to be found, if Dr. Mayo is to prove a true prophet. Nevertheless, the necessity calls forth the men, but the obligation rests on the profession as a whole to ensure that it calls only the best men.—I am, etc.,

Birmingham, June 5th.

W. A. STOKES.

#### INDIVIDUAL MEDICAL DEFENCE.

SIR,—The suggestion that a British Medical Association scheme for individual defence would be in a position to prosecute its own members, unlike the present defence societies, did not originate from me, but from Dr. Manson himself. When Dr. Robinson afterwards states that such a procedure would be *ultra vires*, Dr. Manson, forsooth, deems my ground, not his, is cut away.

On the financial side I cannot see the necessity for

laboured arguments. With the membership of the British Medical Association there can be no difficulty, if the members are convinced of its wisdom and utility.

It is on other grounds,—of policy and higher expediency—I defer to the Medical Defence and London and Counties, who are in a better position for counsel on behalf of clients. "The ethical machinery" of the British Medical Association would occupy an invidious relationship, productive possibly of internecine warfare. Besides, I am not in love with machinery, and prefer ethical education.

I hazard the opinion that the British Medical Association is stronger outside, reserving its influence for matters of moment.—I am, etc.,

London, N.W., June 8th.

RICHARD GILLBARD.

#### FASHIONS AND FADS IN MEDICINE.

SIR,—I read with much amusement and profit Dr. Robert Hutchison's address on "Fashions and fads in medicine" (May 30th, p. 995).

When I was a junior student I spent many hours in the out-patient department sitting at the feet of a (now) fairly distinguished physician, who diagnosed practically every case of dyspepsia as "dilated duodenum." Exactly what this diagnosis was supposed to imply I was never very sure, but in view of subsequent experience I am tolerably certain that many of those patients were suffering from gastric and duodenal ulcers. If we asked questions we were met with specious explanations; and yet that physician was, and is, in many respects an exceedingly brilliant man.—I am, etc.,

June 7th.

AMUSED.

#### ARTIFICIAL PRODUCTION OF THE ANTIRACHITIC VITAMIN.

SIR,—In a leading article on artificial production of the antirachitic vitamin in the *JOURNAL* of May 30th (p. 1011), whilst discussing the activating action of ultra-violet light on substances not containing the fat-soluble vitamins, you say: "This effect is remarkable and unexpected, for Zilva in 1920 had shown that prolonged exposure to ultra-violet light actually destroyed the vitamins in cod-liver oil."

This reference to my work is not strictly accurate. My experiments showed that vitamin A was destroyed if the active oil was exposed to a mercury quartz lamp without taking precautions to prevent the oil from coming in contact with the ozone generated by the lamp. I was, however, able to demonstrate that if such precautions were taken no inactivation took place. Moreover, I found that ozone, even in the dark, destroyed the vitamin.—I am, etc.,

The Lister Institute of Preventive Medicine,  
London, S.W., June 2nd.

S. S. ZILVA.

#### Obituary.

##### MICHAEL DEWAR, M.D.,

Edinburgh.

THE death took place on May 30th at his residence 5, Chalmers Street, Edinburgh, of Dr. Michael Dewar, a well known practitioner in that city.

Michael Dewar was born in Leith in the fifties of last century, and after graduating M.B., Ch.B. in 1876, he held various appointments and began practice in Edinburgh in 1884. In 1890 he took the degree of M.D. at Edinburgh University with honours, presenting as his thesis for the degree "A clinical analysis of 1,000 obstetrical cases." Throughout his practice Dr. Dewar was regarded as an authority on obstetrical matters, and was a keen supporter of the Obstetrical Society of Edinburgh. His interest in this subject was recognized in the fact that at the time of his death he had been for five years deputy chairman of the Central Midwives Board for Scotland. After the passing of the Insurance Act, Dr. Dewar took a great interest in the working of the National Health Insurance system, and he had been for some years a member of the Edinburgh Insurance Committee appointed by the Town Council, for a time also acting as chairman of the Panel Committee. Various papers on medical subjects had issued from his

pen, such as "A clinical study of influenza during the epidemic of 1904-5," "Notes on puerperal eclampsia," an article on "Hospital reform," which appeared in the *British Medical Journal* in 1912, and an article on the "Administrative control of malingering," published also in our columns.

Dr. Dewar's connexion with the British Medical Association had for many years been very close. His duties as an office-bearer began with the honorary secretaryship of the South Edinburgh Division of the Edinburgh Branch, which he held from 1904 to 1910. Between the years 1904 and 1913, and again from 1918 to 1920, he acted as a member of the Edinburgh Branch Council, and in 1911-12 he was a member of the Central Council of the Association. In 1911 he was elected a representative of the South Edinburgh Division at the Annual Representative Meeting, and he acted as honorary secretary of the Edinburgh Branch from 1910 to 1913. His interest in National Health Insurance questions was evinced by his serving as a member of the Insurance Acts Committee of the Association from 1919 to 1922, and at the time of his death he was a member of the Insurance Acts Subcommittee for Scotland. At the Annual Meeting of 1912 he was one of the Vice-Presidents of the Section of Medical Sociology. Dr. Dewar also took a keen interest in local affairs, and for many years he had been session clerk of St. Stephen's Parish Church, Edinburgh. He leaves a widow, a daughter, and a son who for some years has acted as his assistant in medical practice in Edinburgh.

#### JAMES SCOTT, M.B., C.M.Ed.,

Late Governor and Medical Officer, H.M. Prison, Holloway.

An important link with the criminal trials of the past has been severed by the death of Dr. James Scott in a nursing home in London on May 29th.

Born at Leith in November, 1853, he received his medical education at Vienna and Edinburgh, graduating M.B., C.M. with honours at the latter university in 1877. After a period spent on the resident staff of various hospitals in Bristol and elsewhere, he joined the prison service in 1881, entering with the highest testimonials from Lister, Clouston, Matthews Duncan, Grainger Stewart, and others. He first served as assistant surgeon at Dartmoor and Chatham convict prisons, and later became in succession medical officer at Manchester, Stafford, Holloway, and Brixton prisons. It was at the two latter that he gained the opportunity of making full use of his special abilities, for there the remand and trial prisoners of the metropolis and adjacent areas were sent for observation, and he became a familiar figure at the Central Criminal Court, London and Middlesex Sessions, and assize and session courts of the adjacent counties. He was soon recognized as an authority on criminal responsibility, and the judges before whom he appeared frequently expressed their confidence in his opinion. His imperturbability in the witness box was the result of the enormous pains he took in getting up his cases, and his wide experience, technical knowledge, and close attention to detail made him a difficult witness to upset. Although in the course of his duties he was frequently obliged to give evidence against prisoners, they seldom failed to elicit his sympathy, and he would often regret that his evidence was of necessity adverse to the accused. He was never tired of teaching his juniors that if they appeared for the prosecution the accused was entitled to have everything brought out in his favour that might assist his defence. But he never shirked responsibility, and his constant advice to a hesitating junior was to "grow shoulders" upon which to rest the burden. He was a tireless worker, but eventually years of strenuous and often harassing court work began to tell on him, and when he was offered by the Prison Commissioners the governorship of Holloway prison he accepted the appointment and held it until his retirement in 1912.

He was an ideal colleague, unselfish to a degree, always taking his full share of the work, and appreciating to the full such assistance as his juniors could give. He was always ready to teach such of them as were anxious to learn, and to work with him was an inspiration to his juniors. With his special experience and wide store of

knowledge he was enabled to instruct as no textbook could. During these years he was, with other contemporaries in the prison service, steadily and unostentatiously directing attention to the importance of taking into consideration the individual mental condition of prisoners in relation to their treatment; and it is a matter for congratulation that these workers, each in his own sphere, laboured towards the same end, and that their results are effective at the present time. In private life he was exceptionally generous and hospitable; he endeared himself to a large circle of friends, and his constant thought, up to the time of death, was for others. Somewhat late in life he became a Freemason, and during the war his efficiency and energy were of very great value. At the time of his death he held the rank of P.P.J.G.W. A bachelor, he enjoyed the devoted attention of his sister to the end, and to her his numerous friends will extend their deep sympathy.

W. N. E.

#### SAMUEL TAYLOR DARLING, M.D.

In our issue of May 30th we recorded briefly the terrible accident that befell members of the League of Nations Malaria Commission in Palestine on May 20th, and gave an account of the career of Major N. V. C. Lothian, one of the party. Another of those killed by the overturning of the car was Dr. Samuel Darling, who for the past ten years had been a member of the staff of the International Health Board of the Rockefeller Foundation. Dr. Darling was a pathologist of unusual distinction, who made important contributions to the scientific knowledge of malaria, relapsing fever, dysentery, and parasitic diseases, particularly hookworm disease, filariasis, and trypanosomiasis.

He was born in Harrison, New Jersey, on April 6th, 1872. He received his degree in medicine at the College of Physicians and Surgeons, Baltimore, in 1903. From 1906 to 1915 he held the post of chief of laboratories of the Isthmian Canal Commission, Panama Canal Zone. His research studies in tropical medicine during this period won him wide recognition among the medical profession. In 1913-14 he accompanied General Gorgas on a sanitary mission to the Rand Mines and Rhodesia, South Africa. In 1915 he joined the staff of the International Health Board, and for the next three years he headed a medical commission engaged in investigating the causes of anaemia among the people of Malaya, Java, and Fiji. From 1918 to 1920 he served as professor of hygiene and director of laboratories of hygiene in the Medical School of Sao Paulo, Brazil. Since that time he had been director of a field laboratory for research studies in malaria, located at Leesburg, Georgia. He was recently appointed corresponding member of the Malaria Commission of the League of Nations. At the time of his death he was travelling with the Commission, which was investigating the prevalence of malaria in Palestine and Syria.

Dr. Darling was an honorary Fellow of the Royal Society of Tropical Medicine and Hygiene, London, he and General Gorgas being the only Americans so honoured. He had accepted an invitation to deliver the annual address to the society next month. He was also a Fellow of the American Medical Association, and a corresponding member of the following organizations: Helminthological Society, Washington, D.C., the Malaria Commission of the Health Section of the League of Nations, Société de Pathologie Exotique de France, and Sociedad de Medicina e Cirugia de Sao Paulo, Brazil. He was president of the American Society of Tropical Medicine for the year 1924-25. His published works include numerous studies on malaria, dysentery, hookworm infection, trypanosomiasis, and other tropical infections.

Dr. DAVID JOHN LEWIS, who died on April 25th at Machynlleth at the age of 53, received his medical education at the London Hospital and in Edinburgh. He obtained the L.S.A. in 1903, and the diplomas of L.R.C.P. and S.Ed. and L.R.F.P.S.Glas. in 1904. He was elected F.R.F.P.S.Glas. in 1918, and graduated M.D. Durham in 1922. After holding an appointment as a ship surgeon in the Union Castle Line, Dr. Lewis engaged in private practice at Winscombe, Somerset, acting as medical officer

twenty years' service, and retired on December 14th, 1909. He served on the North-West Frontier of India in the Mahsud-Waziri campaign of 1881, and in the Egyptian war of 1882, when he was present in the actions at Tel-el-Kebir and Kassassin, and received the Egyptian medal and the Khedive's bronze star. Most of his service was passed in civil employment in the North-West, now the United Provinces. In 1883 he married Ada, daughter of Mr. Dyer, of Lucknow, who survives him.

UNIVERSITY OF CAMBRIDGE.  
At a congregation held on June 6th the following medical  
degrees were conferred:

M.D.—K. H. Tallerman.  
M.B., B.Ch.—H. Yates, A. R. Jilster, G. F. Lund, J. P. White Janle.  
M.B.—G. B. Tait, H. E. Harris, R. A. M. Scott.

KING'S COLLEGE.

Extensions in the Department of Physiology.

*Extensions in the Department of Physiology.*

At the last meeting of the Senate of the University final approval was given to proposals of the delegacy for extensions to the department of physiology. Building will be commenced at an early date, and it is expected that the new rooms will be ready by the end of the long vacation. By the new building facilities will be provided for experimental research, a professor's room, and for general mammalian physiology. It is formerly occupied by the bacteriology for the teaching of biochemistry, and for staff room. Approval was also given for the establishment of two of the annual value of £100, which can meet the expenses of such research, recognized as teachers of the University institutions indicated:

*St. Mary's Hospital Medical School.*—Mr. W. D. Newcomb (pathology).  
*Maudsley Hospital.*—Dr. F. L. Golla (neurology).  
Applications to—

Applications for grants from the Thomas Smythe Hughes Medical Research Fund, allocated annually for assisting original medical research, must be sent in by June 15th to the Academic Registrar, from whom further particulars can be obtained. The following candidates have been approved at the examination indicated:

FINAL FELLOWSHIP.—Dr. R. A. Keane.  
PRIMARY FELLOWSHIP.—C. J. O'Reilly, J. Owens, M. A. W. Roberts.  
J. Scott.

TERRITORIAL AMBULANCE CHALLENGE SHIELD.  
LONEL E. C. MONTGOMERY-SMITH (secretary)

**TERRITORIAL AMBULANCE CHALLENGE SHIELD.**  
COLONEL E. C. MONTGOMERY-SMITH (secretary) informs us that the competition for the Ambulance Challenge Shield (T.A.) will take place at the Duke of York's Headquarters, Chelsea, S.W.3, at 2.30 p.m. to-day (Saturday, June 13th). Ten units will take part: 143rd (South Midland) Field Ambulance, 12th (Wessex) Field Ambulance, 170th (Cavalry) Field Ambulance, 125th (East Lancs) Field Ambulance, 1st (Casualty Clearing) Field Ambulance, 53rd (3rd Western) Field Ambulance, 7th (2nd London) Casualty Clearing Station, and 23rd Battalion London Regiment.

INDIAN MEDICAL SERVICE.

INDIAN MEDICAL SERVICE.  
As already announced, the annual dinner of the Indian Medical Service in London will be held at the Trocadero on Wednesday, June 17th.  
Lieut.-Colonel A. W. Alcock, C.I.E., F.R.S., will be in the chair.  
Tickets and all particulars may be obtained from the joint secretaries, J. J. Pratt, I.M.S.(ret.), 18, Nevill Mans

DEATHS IN THE SERVICES  
Joseph Sykes, Bengal 25

**DEATHS IN THE SERVICES.**  
Lieut.-Colonel Joseph Sykes, Bengal Medical Service (ret.), died at Polkstone on May 5th, aged 71. He was born at Janmah in the Deccan, and got his first medical education in the Madras Medical College. He entered the Subordinate (now the Indian) Medical Department as a hospital apprentice on June 29th, 1874, and resigned two years later. He then came to Europe, matriculated at Glasgow University, and took the L.R.C.P.Ed. and L.R.F.P.S.Glas. in 1879. He entered the Bengal Medical Service as surgeon on October 31st, 1879, became a Lieut.-Colonel in 1891, and died on May 5th, 1900.

## Medical News.

THE half-yearly dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, June 26th, at 7.45 p.m. All visiting Australians and New Zealanders wishing to be present should communicate with one of the honorary secretaries, Mr. E. T. O. Milligan, Mr. H. Bedford Russell, at 86, Harley Street, W.1.

THE annual summer dinner of the Glasgow University Club, London, is to be at the Trocadero Restaurant, Piccadilly, W., on Friday, July 3rd, at 7.15 for 7.30 p.m. The Right Hon. Augustino Birrell, K.C., LL.D., will preside. Any Glasgow University men who, though not members of the club, desire to attend are requested to communicate with the honorary secretaries, 1, Harley Place, N.W.1.

NOMINATION for the David Lloyd Roberts Lecture is in the hands of the Royal Society of Medicine for this year. Sir Arthur Keith, M.D., F.R.S., has accepted an invitation from the Council of the Society to deliver the lecture on November 16th.

THE annual general meeting of the Royal Society of Tropical Medicine and Hygiene will be held at 11, Chandos Street, W.1, on Thursday, June 18th. A demonstration at 7.45 will precede the meeting. At 8.15 the new President, Dr. Andrew Balfour, C.B., C.M.G., will be inducted. The Chalmers medal will be presented to Professor Warrington Yorke, who will read a paper on "Further observations on malaria made during treatment of general paralysis." Dr. G. C. Low will make an announcement on the use of a drug named "malarina" in the treatment of malaria.

At a meeting of the Central Midwives Board for England and Wales, on June 4th, when Sir Francis Champneys was in the chair, it was decided to inform the M.O.H. Gloucestershire that midwives living in District Nursing Association homes are, according to the general practice throughout the country, subject to the same rules as to supervision as midwives in private practice. It was agreed to place before the Royal Commission on Local Government a statement of the Board's views on the question of the transfer of functions under the Midwives Acts from county councils to other local authorities.

THE Fellowship of Medicine announces that Sir Gerald Giffard will lecture at No. 1, Wimpole Street, on June 17th, at 5.30 p.m., on some Madras methods in the teaching and practice of midwifery. A second course for general practitioners will be held at the London Temperance Hospital from June 22nd to July 4th. The special course in urology at St. Peter's Hospital has been postponed to June 29th to July 25th. From July 6th to 17th an intensive course in cardiology (limited to an entry of sixteen) will be held at the National Hospital for Diseases of the Heart. The Queen's Hospital, Hackney Road, will hold a course in diseases of children from July 6th to 18th, and from July 27th to August 15th the West End Hospital (Out-patients' Department, 73, Welbeck Street) will hold a course in the diagnosis and treatment of nervous diseases. Full particulars of these courses may be obtained from the Secretary, at No. 1, Wimpole Street, W.1.

THE annual meeting of the National Council for the Unmarried Mother and her Child will be held at Carnegie House, 117, Piccadilly, W.1, on Thursday, June 18th, at 2.30 p.m., with Lord Henry Cavendish-Bentley, M.P., in the chair. The annual report will be presented, and a discussion on the Mental Deficiency Act as it affects unmarried mothers will follow.

AMONG the recent recipients of the degree of M.D. at the University of Lausanne were Dr. Charles A. H. Franklin (Sevenoaks) and Dr. Arthur Shirley (London).

DR. F. G. BUSHNELL, who a short time ago ceased to be assistant medical officer of health for Plymouth in circumstances indicated in the SUPPLEMENT of April 25th (p. 186), has been recommended by the Plymouth Public Health Committee for appointment as assistant consulting tuberculosis officer at a salary of £300 a year.

THE second Franco-Polish Medical Congress was held at the Paris Faculty of Medicine, under the presidency of Professor Roger, on April 28th, when addresses were delivered by Professor Roger, Dr. Krzyżtalowicz, rector of Warsaw University, and M. Jules Godard, ex-Minister of Labour and Hygiene.

A COURSE on dermatology and venereal diseases will be held, under the supervision of Professor L. M. Pautrier, in Strasbourg, from September 21st to November 7th. Besides lectures and clinical, bacteriological, and histological demonstrations there will be individual training in the different therapeutic methods, including the use of carbonic snow, radiotherapy, electrolysis, and cauterization. The fee for

the course is 200 francs. A special course in the principal laboratory methods and the general pathological anatomy of skin diseases will be arranged if five applications are received. The fee for the special course is 150 francs. Applications should be made to Professor Pautrier, 2, Quai St. Nicolas, Strasbourg, from whom information may also be obtained with regard to accommodation in pensions on reasonable terms.

THE third congress of French-speaking dermatologists and syphillographers will be held at Brussels from July 25th to 28th, when the following subjects will be discussed: the nature and treatment of tuberculides; the etiology of herpes febrilis and herpes zoster; syphilitic reinfection, pseudo-infection, and superinfection; endocrine disturbances due to inherited syphilis; modern treatment of lupus. Further information can be obtained from the general secretary, Dr. L. Dekeyser, 9, Rue des Sablons, Brussels.

DR. W. H. MAXWELL TELLING, who has occupied the Chair of Therapeutics in the University of Leeds for the past two years, has been elected by the Council of the University Professor of Medicine and head of the Department of Medicine, as from October 1st next, on the retirement from that office of Dr. T. Wardrop Griffith. Dr. R. A. Venle has been elected to the Chair of Therapeutics in place of Professor Maxwell Telling, and Dr. G. W. Watson has been elected to the Chair of Clinical Medicine, which has been vacant since the retirement of Dr. A. G. Barrs.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the British Medical Journal must communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2.

THE TELEPHONE NUMBER of the British Medical Journal is **MUSEUM 9864**. The telephone number of the British Medical Association remains, until further notice, **Gerrard 2630** (internal exchange).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the British Medical Journal, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London.*

MEDICAL SECRETARY, *Mediscera Westrand, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*); telephone: 4737 Dublin, and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*); telephone: 4361 Central.

## QUERIES AND ANSWERS.

### RESPIRATORY DISTURBANCE AFTER MEALS.

A CORRESPONDENT asks for information about the significance and treatment of a symptom characterized by a desire to take a deep breath, with difficulty in completing the final stage. This is sometimes accompanied by frequent yawning. It comes on about twenty minutes after meals and is considerably relieved by alkalis. Is it, he asks, a reflex spasm of the diaphragm, and is any special drug or diet advisable?

### MANGE.

"E. M." writes: Some patients of mine are very nervous about the possibility of mange in their cats being transferred to them or their children. They are compelled to keep them to prevent the house being overrun with mice, and they say their cats always get mange sooner or later. I told them that I was under the impression that each animal had its own parasite and could not transfer it to another animal. A cat gives mange to a cat, a dog to a dog, and so on, but a cat will not infect a dog. I should be glad to know whether I am correct or not in my ideas on this matter.

\*\* Several genera of mange mites infect the domestic mammals, but most of these are not transmissible to man. *Sarcoptes scabiei* occurs in all the domestic mammals except the cat, but in each case a special strain is found which, although indistinguishable morphologically from the other strains, yet

will only live on the other hosts with difficulty. All the strains of *Sarcoptes scabiei* will live on man; but in no case have they been found to cause a severe form of scabies, and it has generally been very easy to treat by the conventional sulphur dressing. "Sarcoptic" mange in the cat is caused by *Notedres cati*, a form closely related to *sarcoptes*. There are now several well authenticated instances of its occurrence in human beings, and Ross in Australia has been able to prove it experimentally. In this case also infection, when it does occur, is not serious, and is easily treated. It is important, however, not to allow dogs or cats with mange to come into contact with children. The comparative rarity of the infection in man is probably due to a biological resistance similar to that existing in human beings against bovine tuberculosis. Cats and dogs also suffer from a form of ear mange and a form of demodectic mange which are not transmissible to man.

## LETTERS, NOTES, ETC.

## SLEEPLESSNESS.

DR. JAMES HOLMES (Bury) writes: With reference to "Scot's" inquiry about sleeplessness in the seemingly healthy, I venture to give my personal experience, hoping it may be helpful to him or others. Acting on a hint from the late Mr. Ernest Hart, a former Editor of the BRITISH MEDICAL JOURNAL, I have, for general sleeplessness, tried and found reading very helpful, provided it is not light literature or matter in which I was very interested. By preference the book should be on a subject as to which I felt I ought to be more or less well informed but in which I was not really interested. I frequently waken near 3 a.m., about the time of the body's lowest temperature, and lie awake for a considerable time, unless I draw an extra rug over me, in which case I generally feel warmer and soon fall asleep.

"M.B." writes in further reply to "Scot" (May 30th, p. 1026): For nearly a year I slept soundly on going to bed, but awoke, to begin with, about 4 a.m. and gradually, after about six months, not later than 2.30 a.m. I took a long holiday but was no better. I then saw a London specialist, who advised a rest cure in a nursing home, which was strictly carried out for six weeks, in bed all the time. My weight when I began the rest cure was 12 st. 6 lb. (about 6 lb. too much, according to height); it had not varied for over twenty years. When I came away from the nursing home I was 14 st., and had not slept at all for five weeks. I had no pain, not the slightest flatulency, but still, after some few months' rest, my insomnia was due entirely to my food. I ate small meals, especially my evening meal, taking for that meal something very simple and no animal food with it; I also masticated my food much more thoroughly. After a few months' careful feeding I have since slept quite well again. I always had a good appetite, and I believe that was the cause of my insomnia. I strictly avoided hypnotics and only took one on three or four occasions. My age at that time was 47.

## STRENGTH OF MERCUROCHROME SOLUTION IN GONORRHOEA.

MR. W. HARRISON MARTINDALE Ph.D. writes:

intended. My firm has devoted attention to the manufacture of this compound in a solid form ready for use. It had no adverse reports of its use. In the 18th edition (p. 675, eighteenth edition) I have summarized statements in the current medical literature on this new remedy. The 25 per cent. solution was mentioned, but the strength seemed to me so high as to necessitate a word of warning, which, therefore, I inserted both at that page and in the preface, p. xvii. At a recent meeting at Montreal of the Inter-State Post-Graduate Assembly of America I understand the mercurial was criticized severely, and it is possible that the strength of the solution is of paramount importance. May I ask that medical men having a copy of the Extra-Pharmacopoeia will be good enough to note on page 675 that, in general, solutions should not exceed 1 or 2 per cent. strength? The misprint was pointed out by Dr. White in the Journal of the American Medical Association (November 29th, 1919, p. 1703), which I have only recently seen. It is there stated that the 2.5 per cent. is the strongest solution used in the urothra.

## WITTY INVENTIONS.

THE Institute of Patent, Lord Askwith is president, has brought to the Central Hall an exhibition of new inventions, many of them so simple and obvious as to make one wonder why nobody ever thought of them before. A good deal of ingenuity has been expended on making the same thing, with the minimum of adjustment, serve two or more different purposes. Thus there is an article of furniture which, by a couple of movements, it can be converted from a bed-motor body which is convertible in a few moments from a motor to a van. A good many small domestic implements also "contrive a double debt to pay." There is a thimble with a cutting mechanism to snap off the ends of thread

or cotton, and there are nut-crackers which not only break the shell but scoop out the kernel, and furnish a toothpick as well. One little device will remove a good deal of embarrassment from afternoon tea parties. It enables a person with a single grip of finger and thumb to hold in perfect balance a plate and a cup and saucer. Many men deserve less well of their kind than the inventor of such a thing as that. Then there are arrangements for preventing windows from rattling or bed quilts from slipping, there are kettles which never boil over, and teapots with lids that cannot fall off. Other inventions are more ambitious. Among several devices for preventing industrial accidents are self-adjusting safety belts for catching falling workmen. Some one has invented a tri-signal indicator for fitting to the rear or side of a motor car. It gives a warning yellow light when the car is turning to the right or off side, a red light when it is slowing down or stopping, and a green light when it is turning to the left or near side. Some of the inventions have a hygienic motive; various new forms of automatic disinfection, cleansing, and deodorizing are exhibited. Other devices include rubber hot-water bottles for wear, either around the waist as belts, or, in the shape of a stole, for placing around the neck and under the arms, for use in disorders of the chest. A vibro-massage apparatus is motorless, but is fitted to the bath tap, and the direction and strength of vibration are regulated at the tap and transmitted through a rubber diaphragm to any part of the body. One invitation of medical interest is the work of a lady (Miss Holmes), and is an apparatus of a simple, compact, and portable kind for artificial pneumothorax; it is being placed on the market by Messrs. Allen and Hanburys. Altogether, the exhibition proves that what the ancient writer calls the knowledge of witty inventions has by no means worked itself out. The ingenuity extends not only to the contrivances, but to the words used to describe them. At every turn one comes across fresh coinages like "passaver," "Axoquick," "gripail," and "cezikary," which make one wonder what the English language is coming to. The exhibition closes on June 15th.

## THE VALUE OF THE GOAT.

THE British Goat Society has published in its Year Book for 1925 much valuable information about this animal, which does not yet receive the attention in this country that it deserves. The considerable economic possibilities of goat-keeping are well described in several short articles, and Dr. B. D. Z. Wright gives several examples of the value of goat's milk in the treatment of various diseases. The large amount of practical details it contains will commend the book to those who keep goats, either as a hobby or for profit, and the numerous interesting articles and good illustrations should secure for it a wide circulation. Copies of the Year Book may be obtained from the office of the British Goat Society, 10, Lloyd's Avenue, E.C.3, price 1s. 6d., post free.

## THE "MOTOR OWNER."

THE Motor Owner, a monthly magazine of motoring, has been issued in a new and improved form. It is a paper which combines amusement with the more serious task of instruction in driving and the use of the roads, and with criticism and descriptive matter. Thus, in the June issue, Mr. S. F. Edge opens a series of "Driving hints from experts." His golden rule is: Never drive faster than the speed at which you know, and can see, that the car can be pulled up. An address on the "Courtesy of the road" by Mr. Stenson Cooke, secretary to the Motor Owners' Club, is reproduced. A harrier-at-law is to be a matter of serious difficulty to the medical motorist—alleged obstruction through leaving a car in a public street. There is an amusing article on police trapping on the new arterial roads which have been built for motor traffic largely out of taxes on motors. Imaginative writing is exhibited in the attribution to a car of the beauty of Venus, the strength of Hercules, and the speed of Mercury. The illustrations are numerous and good.

## "DOCTORS DIFFER."

"E.S." writes: I see that Dr. Robert Hutchison in his interesting and wise address (May 30th, p. 935) repeats the statement that this saying refers to practitioners of medicine. Is he right in this? May it not be that the proverb was applied originally to doctors?

or philosophy, or simply to learned men? Dr. Hutchison raises, too, the individual and the nation of

One would think that to begin with there must be a sincere regard for truth and sympathy; then there should be a knowledge of any particular subject at first hand, or from a reliable source; and the emotions must be subdued to truth. But, of course, people vary in intelligence, in emotional restraint, and in desire for truth; and many subjects are so complex that their principles have not yet been settled. A truth-seeking scepticism and a sense of humour are saving graces.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 44, 45, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 203.

## Remarks ON PAINLESS PELVIC SURGERY.

BY

FREDERICK J. McCANN, M.D. EDIN., F.R.C.S. (Eng.),  
SENIOR SURGEON, SAMARITAN FREE HOSPITAL FOR WOMEN,  
MARYLEBONE ROAD, N.W.

ALTHOUGH the title "Painless Pelvic Surgery" is employed to express an ideal, yet my object is to show that by appropriate care pain and discomfort after pelvic operations may be so minimized that it is justifiable to speak of a "painless operation." The mortality of pelvic operations has been reduced, but post-operative morbidity has not been diminished in proportion to the low mortality rate. An acute or even a chronic painful illness may follow the operation. It is true that this illness may be short and sharp as measured by duration and intensity, but it is none the less difficult to bear; indeed, the mental impression may long remain, and accentuate the "fear of the knife" for all time, besides exerting a subtle effect on the nervous system which may continue for months or years. Vomiting after an anaesthetic is so common that the suffering of the patients is apt to be ignored or forgotten, yet to them its duration may seem interminable and all the while they are racked with pain.

Even this suffering may be dwarfed by the agony endured in consequence of intestinal distension. To be told that "you must bear the pain," or that "every patient has it," is poor comfort when you feel tearing, grinding, and gnawing in your inside. It should be the aim of the surgeon to do his utmost to prevent post-operative pain so that a painless operation may be followed by a painless convalescence. In the mind of the patient the dread of pain after an operation is greater than the dread of the anaesthetic. To prevent pain and discomfort it is essential that certain precautions should be taken before, during, and after these operations.

### PRECAUTIONS BEFORE AN OPERATION.

#### Abdominal Operations.

It is true that the less a woman is disturbed physically or mentally before an operation the better she will be able to face this trying ordeal. Unless the complaint from which she suffers is urgent she should be admitted into the hospital or nursing home at least forty-eight hours before the proposed operation, and in certain cases a longer interval is required. The practice of admitting a patient in the evening and operating on her the following morning, unless in emergency cases, should be condemned.

If an abdominal operation is to be performed the patient should be kept in bed and should be provided with a suitable diet. A dose of castor oil should be given, if she is constipated, but otherwise the intestinal canal should not be disturbed. To give a purgative the previous night to a woman about to undergo an abdominal operation, and to awaken her at 5 a.m. for an enema and a cup of tea when the operation is to be performed at 8.30 or 9 a.m., is a form of "scientific cruelty" which should be abolished. The employment of enemata before or after pelvic operations is a practice I have never favoured. In certain circumstances it may become necessary to administer enemata, but as a routine they should be avoided. Unless skilfully given an enema may cause considerable shock and distress to the patient, whilst after pelvic operations the proximity of the rectum to the wounded area is an additional reason against their use. No one except her nurse or doctor should see the patient on the day of the operation.

When a bed-pan is used for the first time after an operation there is not merely the difficulty in its use which is due to the operation, but in addition nervousness and apprehension may increase the difficulty. For this reason it is essential that the patient should learn to use a bed-pan for micturition and defaecation during the days preceding her operation. This simple precaution will prevent much pain and discomfort and will often obviate the use of a catheter. A sleeping draught is in the

majority of women unnecessary; sodium bromide, 10 or 15 grains in a tumblerful of water, is useful if required.

The time at which an operation should be performed is made to depend on various circumstances, but if it be considered entirely from the point of view of the patient I believe 2 or 3 p.m. to be the best time. The last mentioned hour, however, has the disadvantage of the failing light in the winter, necessitating the use of artificial light should the operation be of long duration. The afternoon operation has the advantage that the first night passes more quickly, whereas if the operation be performed in the morning a long day is succeeded by a still longer night. Moreover, the patient should be permitted to rest undisturbed and not worried in the early hours of the morning by the crude methods of preparation so commonly used. Although individual variations must be taken into account, yet for most women the afternoon is to be preferred. A light breakfast of tea and toast is given at 8.30 and a similar meal at 11 a.m., after which no food is permitted.

The arrangements for dealing with patients about to undergo operations are not satisfactory in most hospitals and nursing homes. The difficulty is not only one of inadequate accommodation, but also of inadequate nursing facilities. To overcome these difficulties the hospital or nursing home must be specially constructed or arranged to facilitate the rapid transference of the patient from her bed to the operating theatre. In a small private hospital for gentlewomen to which I am visiting surgeon the conditions are almost ideal, and a brief description of them may not be out of place.

The patient about to undergo an operation occupies a bedroom on the same floor as the operating theatre. Half or three-quarters of an hour before the operation she is given a hypodermic injection of morphine 1/6 grain and atropine 1/150 grain, her bedroom is darkened, and no one is permitted to see her or speak to her until the anaesthetist arrives to give her the anaesthetic. She is anaesthetized in bed, after which she is placed upon the trolley. The trolley is then wheeled into the operating theatre, a distance of a few yards, and she is carefully lifted on to the operating table. The operating table has the shoulder-pieces padded and a folded blanket is fixed over the central portion of the table by broad webbing laterally and longitudinally, and covered by waterproof sheeting, and pillows are provided for the head.

Much of what may be termed "aseptic discomfort"—uncovered metal tables and trolleys, concrete floors, and so forth—could and should be improved, with great benefit to the patients as suffering human beings and without detriment to the surgical results, immediate or remote. I can only assert that the results which have been obtained in this small hospital have encouraged me in the conviction that all these minor details are of paramount importance, and, thanks to the benevolent lady who presides over this hospital, every detail which would promote the well-being of the patient has been faithfully carried out. These precautions have had a marked effect in diminishing or counteracting post-operative shock and post-operative pulmonary complications.

To employ such a system in a hospital it would be necessary to have several single rooms on the same floor as the operating theatre, for the present method of bringing a patient some distance to an anaesthetizing room, and after operation taking her back again, implies considerable disturbance and exposure to the air of cold and often draughty passages. Yet something should be done to prevent those all too frequent pulmonary complications which in many instances are contracted during this perilous journey. Unless a nursing home is specially constructed such a system is wellnigh impossible, and yet many struggle on even without the assistance of a passenger lift.

Again, the heating of the operating theatre calls for careful supervision. It is difficult to obtain that happy medium between cold and excessive heat, for the latter is not merely trying to the patient but to all those present. A patient, sweating profusely after an operation, who is wheeled out into a cold and draughty passage, is fortunate if she does not develop some pulmonary complication. A cradle covered with a blanket over her head, or other

suitable device, should be employed to retard the ingress of cold air, and a sufficient number of warm blankets should envelop her body.

#### Vaginal Operations.

Women suffering from genital prolapse require a longer period of rest in bed before operation. The prolapsed uterus and vaginal walls should, as far as possible, be replaced, thus permitting congestion to diminish; at the same time any uterine or vaginal discharge should be treated, as well as any ulcerated or abraded surface.

For the treatment of a vaginal discharge irritating injections should not be used, and the injections should not be too hot. For ordinary routine use an injection of salt solution, 2 drachms to the pint, comfortably warm, is most useful. Hot irritating injections tend to cause oedema of the vaginal walls and delay in healing, with consequent discomfort to the patient.

The present fashion is to shave the vulvar hairs completely before a vaginal operation, and I have known this done even before the removal of a urethral caruncle, whilst it is the common practice before curettage. In the unclean shaving of the vulvar hairs may be a necessity, but in those of cleanly habit it is not only unnecessary, but too often leads to local discomfort after the operation. Moreover, the vulvar hairs are an important protection, and can be rendered clean and kept clean. Lister did not advise shaving the head in the treatment of scalp wounds; on the contrary, he disinfected the hairs and made use of them as a further protection to the wounded surface. For these reasons I have never favoured routine shaving of the vulva, which is, moreover, distasteful to the great majority of female patients. My results fully justify me in adhering to this opinion.

#### PRECAUTIONS DURING AN OPERATION.

##### Abdominal Operations.

I do not believe it is sufficiently realized how much can be done during an operation to prevent post-operative pain and discomfort. If the art of surgery is to develop as it ought, and if it is to become one of the fine arts, then the "tearers" and the "bruisers" must give place to a race of surgeons who will be respecters of human tissues, causing the minimum amount of traumatism, and who will accomplish their task with that refinement of execution known only to the highly skilled artist.

Vision is too often fogged by a display of mortality statistics, and although the day when operations will have no mortality may be not far distant, let us see to it that they will also have no morbidity. The surgeon of the future should be able to assure the patient about to undergo an operation that it is devoid of risk, and that the convalescence will be free from pain and discomfort.

Iodine is probably more frequently used in different parts of the world in the preparation of the skin of the abdominal wall than any other medicament. I have abandoned its use for some years because it tends to cause local irritation, and as a cleansing agent is not so good as methylated spirit and acetone. These agents can be recommended as effective cleansers of the skin which do not cause irritation, provided that the methylated spirit be of good quality.

To avoid the leg-aches, the knee-aches, and the shoulder-aches, it is essential that the patient should be securely fixed when the operating table is elevated into the so-called Trendelenburg position. Few operating tables are capable of affording a correct position, the fault being that they are not provided with leg-pieces. In some the patient, when elevated, hangs by the knees without shoulder supports; in others with shoulder supports the ankles are fixed by a bandage; or again, the legs are elevated and the whole weight of the body is sustained by the shoulder supports. It is thus easy to comprehend why patients so fixed complain of what is called "rheumatism" during convalescence.

The operating table should therefore be provided with leg-pieces as well as shoulder supports. The patient should be so fixed on the operating table when elevated into the Trendelenburg position that the knees are flexed, the thighs slightly flexed and abducted, and the shoulders supported.

In this position there is a more equable distribution of strain, and it is surprising how much better the abdominal wall is relaxed. Moreover, ready access is obtained to the vagina should any combined procedure be required, and there is no "rheumatism" during convalescence.

The operating table should be elevated before the surgeon begins the operation, and he should be able to tell by the contour of the abdominal wall if the intestines have descended towards the diaphragm. The patient should be deeply anaesthetized before the incision is made, and if kept under the anaesthetic it will be found, on opening the abdomen, that the intestines have fallen back and a large abdominal sponge can be inserted and spread out so as to retain the intestines in their position. Too often, owing to incomplete anaesthesia and straining, there is a battle between the protruding intestines and the surgeon, ending in the defeat of the former after much handling and exposure, and it is doubtful if as good retraction is ever obtained under these conditions.

The ability to use a knife is one of the greatest achievements of the accomplished surgeon. If the tissues of the abdominal wall be cut cleanly with a sharp knife they heal better, they are easier to coapt by stitches, and subsequent pain is diminished. When the abdomen is opened the abdominal incision should not have the appearance as if it had been eaten by rats. A sharp knife should also be used for the separation of adhesions, and not scissors, or, worse still, a gauze sponge.

Both the skin and the divided abdominal wall should be protected. After a trial of various materials I have come to the conclusion that the best protector of the divided abdominal wall is the peritoneum. For this purpose sterilized cloths are fixed by toothed forceps to the parietal peritoneum. The abdominal wall and skin being protected, and the intestines completely covered, the contents of the pelvis are exposed to view. The large abdominal "sponge" (made of lint) is steeped in hot normal saline solution, and no irritant fluid is used within the abdominal cavity. Large abdominal retractors of the self-retaining pattern are best avoided on account of the injury they do to the parietal peritoneum by pressure. Indeed, the less the abdominal wall is retracted by instruments the better for the future comfort of the patient.

In a paper entitled "Suggestions for the prevention of post-operative embolism and thrombosis" I have already indicated many points in technique which not only prevent embolism but also prevent post-operation pain. Amongst the foremost of these are: (1) the avoidance of transfexion and puncturing of blood vessels; (2) accurate haemostasis; and (3) the avoidance of mass ligatures.

It is a good rule in surgery "never to transfix a vascular area," and the reasons why this rule should be observed are fully set out in this paper.

Accurate haemostasis is one of the most important means of preventing pain, for blood effused into the peritoneal cavity probably causes more pain than any other fluid, even more than that produced by the gastric or intestinal contents. Blood effused under the peritoneum—as, for example, after the operation of supravaginal hysterectomy where the haemostasis has been incomplete—probably causes pain by tension and stretching of the peritoneum should the sutures effectually prevent the blood escaping into the peritoneal cavity.

Effusion of blood into the abdominal wall from incomplete haemostasis is a common cause of pain. This effusion causes tension, and is evidenced at a later stage by the formation of a haematoma. For this reason it is wise to tie or twist bleeding points in the abdominal wall, especially at its lower end, and to make sure that all haemorrhage is arrested. It is a good plan to place a gauze sponge, held in long forceps, at the bottom of the pelvis before the operating table is lowered from the elevated position. The object of this sponge is to soak up any blood which has collected, as well as to indicate if additional bleeding has occurred after the horizontal position is resumed. If there be any bleeding it is likely to be increased during vomiting and straining as well as from the vascular reaction which occurs after every abdominal operation of any severity. Although this amount of bleeding

may not endanger the life of the patient, yet it causes pain, and should be prevented.

I believe it to be important to lower the operating table into the horizontal position before suturing the abdominal wall, and to "arrange" the abdominal contents so that the sigmoid colon covers the pelvic cavity, and the omentum is spread over the intestines. The withdrawal of the large abdominal sponge should be delayed until the peritoneum is partly stitched, and if the sponge be pulled gently downwards towards the symphysis pubis the omentum comes down with it. Chilling and exposure of the intestines are thereby diminished.

Subcutaneous emphysema may result from neglecting to lower the elevated table, and may cause considerable discomfort for some days. Again, volvulus of the small intestine, with accompanying signs of intestinal obstruction, may result from a similar cause, whilst it is difficult to be certain that all haemorrhage has been arrested when the abdomen is closed with the pelvis elevated.

The wound in the abdominal wall is a great source of pain, and too much care cannot be taken to cut cleanly, to avoid bruising and tearing, and to arrest all bleeding. The method of suturing is all-important, and here it is not so much the material used as the manner of its use that matters.

Stitches only act as splints, and yet how often this is forgotten. It is "Nature's glue" which produces union, and without this assistance all the efforts of the surgeon would be vain. The function of a suture is to maintain the opposing surfaces in apposition, and Nature does the rest. In suturing there should be that nicety of adjustment, that apposition without constriction, which is the hall-mark of the finished craftsman. The peritoneal edges should be apposed by a suture which is not pulled too tight and by which the edges are not constricted, and thus the thinnest suture material can be employed without breaking it. Again, the type of through-and-through abdominal suture in common use causes considerable pain. It is inserted at a distance of an inch or more from the cut edges, taking up skin, fat, fascia, muscle, and sometimes peritoneum, and then is tied firmly, encompassing within its grasp a mass of tissue which writhes and struggles in vain until relief comes with removal of the suture.

To overcome this difficulty I have used for some years a figure-of-8 suture of silkworm gut. It is inserted on one side, a quarter of an inch from the skin margin, passing through skin and fat, then it is passed through fascia and muscle on the opposite side, taking a good grip of both, and again through muscle and fascia on the same side, and finally through fat and skin on the opposite side, emerging a quarter of an inch from the skin margin. A piece of fine india-rubber tubing half an inch in length is threaded over one end of the suture, which is then tied so that the skin edges are apposed—not constricted—and the small piece of rubber tubing lies flat upon the line of the incision. Sutures so inserted may remain in position for fourteen days or longer. Preliminary scratching of the skin at intervals during the position of the incision ensures accuracy in suturing.

Before the figure-of-8 sutures are tied the muscle and fascia are united by catgut, continuous or interrupted according to requirements, and the skin by Michel clips. In the application of these clips it is essential that the skin edges be apposed and not crushed. Crushing not only causes pain, but redness and sloughing. If clips be carefully applied they may be left in position for a week without even causing redness of the skin edges. Skin edges apposed and not crushed heal rapidly without pain. A dressing of double cyanide gauze fixed in position by collodion is then applied, care being taken that only the edges of the covering layer of gauze are so fixed. A pad of wool and a many-tailed bandage complete the dressing.

The practice of fixing the gauze dressing by means of the through-and-through sutures has such obvious disadvantages that it cannot be recommended.

#### Vaginal Operations.

As already mentioned, it is important to use non-irritating antiseptic solutions and to see that they are not too hot, in order to prevent oedema of the tissues and subsequent dis-

comfort. After thorough cleansing of the vulva it is disinfected with acetone followed by mercury biniodide solution 1 in 2,000. The vagina is swabbed out with the mercury biniodide solution and then thoroughly dried with gauze sponges. I believe many vaginal operations fail through neglecting this simple precaution, for moisture in this region favours septic infection.

Hæmostasis is of paramount importance in vulvar and vaginal operations. Bleeding points should be caught and tied, not left to chance. Secondary hæmorrhage is far too common after these operations, many of which are regarded as minor operations, and sufficient trouble is not taken to see that all bleeding is stopped. There may be troublesome vaginal hæmorrhage after the operation of colpoperineorrhaphy, or the effused blood may form a hæmatoma in the perineal tissues, causing local pain and discomfort. Such results may be due to septic infection or the neglect to tie or crush bleeding vessels, especially veins. After the operation of colpoperineorrhaphy the bleeding usually comes from two small arteries at the apex of the triangular flap, excised from the posterior vaginal wall. The patient complains of pain, she is restless and somewhat blanched, often unable to urinate, and yet her vagina may be distended with clotted blood, although the amount of external blood loss is small.

Secondary hæmorrhage is still more frequent after operations on the cervix uteri. Cervical tissue heals slowly and its blood vessels have a tendency to retract within its substance, thus favouring secondary hæmorrhage. From a study of the writings of the older authors secondary hæmorrhage does not appear to have been a common complication of operations on the cervix uteri because a non-absorbable suture, most frequently silver wire, was used which was allowed to remain until healing was complete. The modern use of catgut is responsible for much secondary hæmorrhage, because too often the catgut melts before Nature has glued the apposing surfaces together. If catgut be employed it must be forty-day chronic catgut, but who can guarantee that it will hold? I have obtained the most uniformly successful results in operations on the cervix by the use of silkworm gut, but unfortunately such sutures require to be removed, whereas catgut becomes slowly absorbed and does not require removal. If the catgut employed will remain for the requisite time secondary hæmorrhage will not occur, but who can tell when it is reliable? The announcement that the catgut will last forty days is a pious opinion; it is not always a statement of fact.

For the major vaginal operations of hysterectomy and colpotomy accurate hæmostasis is one of the secrets of success. "Get it dry and keep it dry" should be the guiding principle in vaginal surgery.

Women appear to dread perineal operations more than any other. They seem to have heard of the pain following the operation, of the pain when the stitches are removed. Their fears are certainly justified unless the surgeon takes special precautions to prevent pain. A perineorrhaphy may be, and often is, one of the most painful operations in surgery, yet with care the pain can be prevented. The perineum should be stitched in the same manner as the abdominal wall. To constrict tightly a mass of perineal tissue within the grasp of a suture is to cause not pain but agony—agony which is accentuated by the oedema of the tissues which supervenes.

The through-and-through sutures, which should be of silkworm gut, should be inserted, and should emerge a quarter of an inch from the margin of the incision, and after the superficial skin sutures of catgut have been inserted and tied the silkworm gut is tied, one end being threaded through rubber tubing as in the abdominal wall. The common error is to constrict an unnecessarily large amount of skin within the grasp of the suture and to pull it too tight. The sutures must be tied with that nicety of adjustment which comes with practice and experience.

It may be urged that by the use of catgut only pain is prevented. This is true—if the catgut were always reliable; but even if it were, infection may defeat the efforts of the surgeon. I consider it essential in these operations to use a non-absorbable suture, which not only acts as an efficient splint but also as a second line of defence to the catgut sutures.

The nicety of adjustment to be achieved in suturing the perineum is most important in the recent tears following childbirth, where a certain amount of oedema is constantly present. I have often been told by practitioners that they have abandoned silkworm gut because it "cuts out." The real explanation, however, is that the suture has been pulled too tight, and that the oedema which follows has made it tighter, and it cuts the tissues, meanwhile causing unnecessary suffering to the patient. Interrupted catgut sutures fortified by silkworm gut yield the best and most certain results in this department of surgery.

Curetting is an operation which should not be followed by pain if care be taken. Pain may be produced through the character of the cervical dilatation, the vigorous use of the curette, or the application of irritants to the interior of the uterus.

1. *The Character of the Cervical Dilatation.*—The tissues of the cervix should be slowly stretched by the cervical dilators; this stretching is only possible up to a certain size of the dilator employed, and this size varies according to the dilatibility of the cervix. Large dilators do not dilate—they lacerate; and not only haemorrhage, but pain, follows this accident—pain which may persist in consequence of cicatricial tissue forming in the cervical wall and parametrium. The preliminary use of a glycerin ovule, pushed up against the cervix, aids materially in softening cervical tissues whose consistence, as detected by a local examination, suggests interference with easy dilatation.

2. *The Vigorous Use of the Curette.*—A sharp curette may cause chronic uterine pain through the excessive removal of uterine tissue. It should not be used for the body of the uterus, but should be reserved for the cervix. The curette should be held lightly in the hand, and should be used more as a rake than a scraper; this is especially necessary in the post-abortion uterus. The possibility of perforating the uterus and of causing tubal inflammation must be borne in mind by the inexperienced.

3. *Application of Irritants to the Interior of the Uterus.*—It is difficult to understand why this useless procedure is continued in the practice of gynaecology. The only apparent result is that the patient has uterine pain for three or four days after the curetting. It is sufficient for all practical purposes to dry the interior of the uterus, or if it bleeds freely to introduce a gauze plug to arrest the bleeding. The gauze plug is removed at the end of twenty-four hours, and no further local treatment is employed.

#### PRECAUTIONS AFTER AN OPERATION.

##### *Abdominal Operations.*

The patient should be placed in a warm bed upon her side, with one pillow under her head, so arranged that the act of vomiting may be facilitated—that is, with the head slightly inclined forwards, resting on the edge of the pillow. To place a patient in the dorsal position and twist her neck on one side as soon as she begins to vomit is not the last word in surgical art. There may be reasons for adopting other positions, but it must always be borne in mind that the dorsal decubitus interferes with vomiting, and even in the so-called Fowler position, employed many years ago at the Samaritan Free Hospital by Sir Spencer Wells, if the patient lies on her side the act of vomiting is facilitated.

Vomiting still remains one of the most troublesome sequelae of an anaesthetic. I have made many attempts to prevent post-anaesthetic vomiting by drugs and by washing out the stomach on the operating table, but have come to the conclusion that it is best to encourage vomiting and rid the stomach of the ether-laden mucus, which seems to collect even after the stomach has been washed out. For this purpose copious draughts of sodium bicarbonate and water should be given, and ordinary water, hot or cold according to the desire of the patient, swallowed (not sipped) *ad libitum*. Moreover, when vomiting does not occur, nausea may continue for some days, accompanied by distaste for food, which is even more trying to bear.

The amount of post-operation pain when the foregoing precautions have been taken is so trifling that even an injection of morphine is rarely required. However, if there be severe pain which persists, it is wiser to administer an

anodyne and repeat it rather than to allow the patient's suffering to continue.

After the first night the amount of what may be termed "traumatic pain" is, after a carefully performed operation, comparatively trifling. Another factor, however, comes into play—to wit, intestinal pain. This is prevented by the careful covering of the intestines, thus preventing exposure with consequent drying and chilling, the avoidance of drastic purgation before the operation, and the early administration of solid food after the operation.

I think I may fairly claim to have been a pioneer in advocating the early administration of solid food after abdominal (gynaecological) operations. Solid food cleans the mouth better than any mouth-wash; it stimulates peristalsis and encourages the bowels to act naturally. Those who have seen, as I have seen, the older methods of treatment, where patients were fed for days on a liquid diet, are able to appreciate the advantages of solid food. Foul mouths, often followed by parotitis, intestinal pain and distension, obstinate constipation—all these, together with general malaise and wretchedness, combined to make the patient look and feel the victim of a severe illness. All this has been changed through the improvement in the methods of pre-operative, operative, and post-operative care, and amongst the last the early administration of solid food is of first-rate importance. In all my cases of intestinal suture, whether of the small or the large intestine, solid food has been administered after the post-anaesthetic vomiting has ceased, and with the happiest results.

Moreover, I would plead for the systematic dieting of patients who have undergone abdominal section. Briefly, their diet should be so planned that those foods which, singly or in combination, tend to the production of flatulence should be excluded. Too little attention is paid to this most important question, yet for the comfort of the patient it is essential that a suitable diet should be prescribed by the surgeon instead of leaving the task to others.

I suppose no subject has been more frequently debated than that of the administration of purgatives after abdominal section. The time at which a purgative is first administered varies in the practice of different individuals, some giving purgatives at once, others after three days, and so on. I have always advocated "leaving the bowels alone" until the patient is uncomfortable, and then she receives a dose of castor oil. My reason for so doing is that rest is the best therapeutic agent in medicine, and I decline to believe that an early movement of the bowels, with the pain, difficulty, and discomfort it entails, is in the best interests of the patient. Moreover, the disturbance in the abdomen through increased intestinal peristalsis and movement may interfere with reparative processes, whilst the employment of purgative enemas is still worse. For these reasons it is best to refrain from purging the intestine for four or five days, and then a purgative may be given if the bowels have not acted naturally. After the bowels have acted it is wise to ensure a daily action by means of a laxative, which will be found to cause little, if any, discomfort when a preliminary period of rest has been enjoined.

Yet another debated question is: When should the patient be permitted to get out of her bed after an abdominal operation? My answer is that she should be permitted to get out of her bed on the seventh day, provided always that she is having an uninterrupted convalescence. I dress the wound for the first time on the seventh day and remove the Michel clips. The patient is then permitted to leave her bed, unassisted if possible, and sit in a chair for half an hour and then return to bed. This is continued daily, the length of time being gradually increased, until the wound is again dressed on the fourteenth day, when the through-and-through sutures are removed. During the following week the patient walks about her room or in her ward, gradually increasing the amount each day, and this is continued for yet another week, when she is discharged, being then able to walk erect with confidence. I was led to adopt this method after observing the "bent up" women with unsteady gait, emerging from hospitals and nursing homes, whose prolonged rest in bed had materially affected their power of locomotion.

This "early rising," however, possesses still further advantages: it stimulates the circulation, thereby aiding in the prevention of post-operative embolism and thrombosis; it promotes the coaptation and healing of the abdominal wound; it prevents or alleviates those difficulties in micturition so commonly experienced after extensive pelvic dissections; and, by giving the patient hope and confidence, the bodily functions are improved, so that she not only sleeps better but digests and assimilates her food better.

The effect on the abdominal wound is quite remarkable, for I have seen the edges so pressed together in an obese patient that the small pieces of rubber tubing were completely hidden from view. When the dorsal position is maintained for any length of time there is a tendency for the edges of the incision to be dragged asunder, often aided by a varying amount of intestinal distension, whereas the contraction of the recti muscles brought into play in assuming and maintaining the erect posture of the trunk serves to coapt the edges. Although no apparent change may be observed in the skin, yet the subjacent fasciæ, and more often the muscle, may have undergone separation. This is evident long after the operation, and may be demonstrated by placing the hand over the incision with the patient in the dorsal position, and then asking her to raise herself, when it will be found that the muscles are not united and there is not infrequently a bulging produced along the line of the incision. For all these reasons I have become a strong advocate of "early rising" whenever permissible. I do not, however, believe in permitting patients to leave the hospital or nursing home too soon, for it is to their interest to be kept under observation until they are able to walk with confidence. The practice of "early getting up" and "early getting out" is not to be recommended.

As the use of a catheter, especially if not skilful, causes both pain and discomfort, every effort should be made to favour the natural action of the bladder, whilst the danger of infection is an additional reason for avoiding a catheter. The removal of the Michel clips and the through-and-through sutures should be practically painless, if properly done. The early removal of the through-and-through sutures deprives the wound of the advantages of a splint, whereas if they are not removed and the patient gets up, firmer union is obtained. It only remains to be added that the dressing of antiseptic gauze fixed in position by collodion is removed after the collodion is dissolved by acetone, thus rendering the removal painless.

#### Vaginal Operations.

The routine employment of douches after vaginal operations is not to be recommended. Indeed, the less that is done in the way of local treatment or manipulation the better for the patient. The use of an antiseptic "wash" after defecation or micturition is helpful in favouring local cleanliness, and the employment of a special dusting powder favours dryness and relieves pain.

To the patient the most dreaded event is the removal of the perineal stitches, but if these are tied over small pieces of fine india-rubber tubing the removal of the stitches is painless. Where stitches have become embedded through constriction and subsequent oedema their removal may not only be very difficult, but very painful.

Both in incomplete and especially in complete perineal tears I believe it is best to leave the bowels undisturbed for four or five days in order that healing may be uninterrupted.

The other details in the after-treatment of vaginal operations should always be carried out so as to avoid pain and discomfort to the patient. A longer period of rest must be enjoined after operations for genital prolapse, in order that the newly united tissues may become thoroughly consolidated before the erect position is assumed. It is wise to keep such patients in bed for at least three weeks.

Although I must plead guilty to having dealt with what may be regarded as trivialities, yet, after all, it is the little things that matter. Too often it is forgotten that an operation is to the surgeon but a part of his daily work—to the patient it is a great adventure.

## A STUDY OF THE EFFICIENCY OF STERILIZATION OF DRESSINGS.

BY

R. J. B. HALL, M.B., AND A. W. CHAPMAN, M.Sc.,  
CH.B. N.Z., A.I.O.,

LATE SENIOR RESIDENT OFFICER,  
JESSOP HOSPITAL FOR WOMEN,  
SHEFFIELD;

DEMONSTRATOR IN CHEMISTRY,  
UNIVERSITY OF SHEFFIELD.

### INTRODUCTORY NOTE

BY

MILES PHILLIPS, M.B., F.R.C.S.,

Professor of Obstetrics and Gynaecology, University of Sheffield.

THE honorary surgical staff of the Jessop Hospital, Sheffield, watched the experiments described in the paper by Mr. R. J. B. Hall and Mr. A. W. Chapman with great interest. They were satisfied that the observations and deductions were correct. It is valuable to have obtained corroboration of the suspicion that the permeability by steam of surgical dressings, etc., is greatly influenced by the nature of the container and the compactness of the contents. Lightly packed hessian bags are evidently much more easily sterilized than tightly packed metal drums.

However, the chief interest lies in Mr. Chapman's clever device for detecting not only the highest temperature reached, but the duration of time for which that temperature has existed. Most surgeons must have desired such a control. Here it is to hand, and it can be easily and inexpensively employed, as the tubes only cost 40s. to 50s. a gross.

At the Jessop Hospital these controls have been constantly employed for over a year and the surgical staff derive great comfort from their use. They take this opportunity of thanking Mr. Chapman and Mr. Hall for the skill and trouble displayed by them in inventing the control and in elucidating the details of its correct use.

#### OBJECT OF INVESTIGATION.

If a package or drum of dressings is to be sterilized efficiently the steam must penetrate to the centre of the package and raise it to a temperature sufficiently high to destroy any micro-organisms present. In addition to the occasional use of maximum thermometers, many tests have been employed to indicate the temperature in the centre of the dressings. Usually they depend on the fusion or rapid colour change of an organic compound, or, more recently, on the fusion of small pieces of standard alloys.<sup>1</sup>

If complete security is to be attained, the materials to be sterilized must not only be raised to a sufficiently high temperature, but must be kept at that temperature for a certain length of time. All the tests previously employed suffer from the common disadvantage of recording only the maximum temperature in the dressings, without giving any indication of how long it has been maintained. A simple type of indicator has been devised, the reading of which depend both on temperature and time, and hence give a more trustworthy index of the efficiency of sterilization than one recording temperature alone.\*

#### Indicator for Checking Sterilization.

The indicator consists of a small, stout, sealed glass tube containing a few drops of a standard solution of glucose and sulphuric acid. When heated to a sufficiently high temperature the solution slowly darkens in colour and finally chars. The concentrations of acid and glucose are so adjusted that at 212° F. the change in colour is very slow, whilst at 239° F. the solution becomes straw-coloured after five minutes, bright yellow after ten minutes, deep brown after twenty minutes, and nearly black after thirty minutes.

A series of experiments was carried out to determine whether the colour developed in the test solution was a satisfactory index of sterility under the ordinary conditions employed for dressings. A number of sterilizing drums,

\*The device is made and sold by Messrs Albert Browne, Ltd., Chancery Street, J.

were packed with gamgee tissue and towels, some tightly, others loosely, and among the contents of each drum one or more of the control tubes were enclosed. Beside each control tube was placed a small glass tube containing a sporing broth culture of *Bacillus subtilis*. The drums were treated at various pressures for different times in a pressure steam sterilizer and then opened. The control tubes were matched against a colour scale prepared from tubes heated at 239° F. for known times, and the culture tubes were opened under aseptic conditions and subcultured to test for sterility. In all, 47 comparisons were carried out, the results of which are summarized in Table I.

TABLE I.

Group.	Number of Tests.	Subculture Results.	
		Sterile.	Growth of <i>B. subtilis</i> .
A. Colour of control tube indicates exposure to 239° F. of 20 minutes or more	24	23	1(?)
B. Colour of control tube indicates exposure to 239° F. of between 10 and 20 minutes	9	7	2
C. Colour of control tube indicates exposure to 239° F. of less than 10 minutes	14	0	14

It was therefore concluded that when the colour of a control tube enclosed in a package of dressings corresponded with exposure to 239° F. for not less than twenty minutes, the material had been efficiently sterilized, whilst a lighter colour indicated at best doubtful efficiency.

#### Factors Influencing the Penetration of Steam into Dressings.

A few preliminary tests showed that under ordinary conditions steam frequently fails to penetrate to the centre of a drum of dressings even when these are not very tightly packed. This observation has recently been confirmed by Black.<sup>1</sup>

Experiments were accordingly carried out to determine the factors influencing the penetration of the steam through the dressings. It was found that the tightness of packing was one of the most important. How tightly a drum may be packed with safety depends on various considerations, such as size of the drum, the degree of evacuation attainable, the nature of the material to be sterilized, and the pressure of steam and duration of heating which can be employed without damaging the outer layers of dressings. Efficiency can only be attained by trial in each case, but the following experiment illustrates the bad effect of packing too tightly.

#### Experiment on Packing.

Three metal drums, each 11 by 9 by 9 inches, were packed evenly with gamgee tissue. The drum which was most tightly packed contained roughly twice as much as that most loosely packed. Control tubes were placed in each drum in the positions indicated in the table and in some cases were accompanied by small maximum thermometers. A control tube and thermometer were also placed unprotected inside the sterilizer to afford a check on the conditions outside the drums. All three drums were sterilized simultaneously. The sterilizer was first evacuated to a negative pressure of 16 inches of mercury, and steam was then admitted. The process was completed by drying in a current of hot air for one hour. The results obtained are shown in Table II, the control tube readings being expressed as number of minutes' exposure to 239° F.

It will be seen that whilst it was possible to obtain adequate penetration of the steam even into the most tightly packed drum, the length of time necessary to produce efficient sterilization in this case was so long that the outer layers of material would soon be damaged by repeated treatments. Similar experiments with linen towels and cotton abdominal sheets yielded completely analogous results.

#### Comparison of Drums and Bags.

Experiment showed that, within the limits found in the types of drum commonly used, variation in the area of the holes for the entrance of steam made little difference to the penetration. When, however, the dressings were enclosed in a hessian bag of similar size and shape to the drum,

TABLE II.

Drum and Weight of Contents.	Position of Control Tube and Thermometer.	Heating 1.		Heating 2.		Heating 3.	
		20 mins. at 15 lb.		20 mins. at 20 lb.		1 hour at 20 lb.	
		Max. Temp.	Tube Reading (mins.).	Max. Temp.	Tube Reading (mins.).	Max. Temp.	Tube Reading (mins.).
A.—1 lb. 12 oz.	1. Middle of drum one-third way up	235	10	246	10		
	2. Middle of drum two-thirds way up	213	20	243	10		
	3. Edge of drum against holes at side	—	20	—	30+		
B.—2 lb. 10 oz.	4. Middle of drum one-third way up	173	2	199	6		
	5. Middle of drum two-thirds way up	204	4	205	8		
	6. Edge of drum against holes at side	—	30+	—	30+		
C.—4 lb.	7. Middle of drum one-third way up	176	2	181	4	266	30+
	8. Middle of drum two-thirds way up	176	4	187	4	251	30+
	9. Edge of drum against holes at side	—	30	—	30+	—	—
Control	Uncovered in sterilizer	246	30	257	30+	263	30+

the increased area available for the entrance of the steam resulted in greatly increased penetration. There can be no doubt that, whatever the disadvantage of bags for storage purposes, they are much more efficient than metal drums for the actual sterilizing process.

#### Conclusions.

To ensure efficient sterilization it is necessary that the articles be packed loosely in bags or in adequately perforated drums. The pressure of steam and time of sterilization must be adjusted according to the material being treated so as to ensure complete penetration without damage to the goods.

Satisfactory control of the process can best be assured by placing in the centre of the materials an indicator such as that described, the changes in which depend both on temperature attained and the duration of exposure to that temperature.

We desire to express our thanks to Miss C. D. Tingle, M.B., Ch.B., who kindly conducted all the bacteriological examinations.

## A CLINICAL STUDY OF ENCEPHALITIS LETHARGICA.

BASED ON SIXTY-TWO CASES.\*

BY

A. GORDON GULLAN, M.D. LOND., F.R.C.S. ENG.,  
M.R.C.P. LOND.,

HONORARY PHYSICIAN, LIVERPOOL STANLEY HOSPITAL; LECTURER ON  
CLINICAL MEDICINE, UNIVERSITY OF LIVERPOOL.

The present outbreak of encephalitis lethargica was admirably described by Von Economo<sup>1</sup> in May, 1917, in a classical description in which somnolence, ophthalmoplegia, and profound asthenia are given as diagnostic criteria. It must not, however, be forgotten that even in April, 1917, Cruchet, Montier, and Calmette recorded a series of 40 cases of "subacute encephalo-mylitis" before the Société Médicale des Hôpitaux de Paris<sup>2</sup>; these cases had occurred in the winters of 1915-16 and 1916-17. Thus the disease was recorded in France and Austria almost at the same moment.

Dr. Crookshank<sup>3</sup> traces the disease back to the time of Hippocrates, and shows that during the last 450 years there have been a number of epidemics in various countries of Europe. It is worthy of note that during the twenty or

\* A paper recently read before the Liverpool Medical Institution.

thirty years prior to 1917 several isolated cases of encephalitis had been described, but their significance was not detected at the time.<sup>4</sup>

The epidemic nature of encephalitis lethargica indicates that the disease is due to a specific organism. The work of Loewe and Strauss, confirmed by Thalhimer, Levnditi, Harvier, McIntosh, Turnbull, Ottolenghi, D'Antona, Toniatti, and others, merits the highest commendation of having established the closest relationship between organism and disease.<sup>5</sup> The two first claim to have discovered the specific organism. Crookshank and other authorities have drawn attention to the relation of outbreaks of encephalitis with epidemics of influenza. I would suggest that the obscure conditions which favour an epidemic of one disease may at times also favour the outbreak of the other. It remains for the bacteriologists to complete the separation of the two diseases.

Clinically, it is to be noted that the headache of influenza is usually frontal, whereas that of encephalitis is not uncommonly occipital. Moreover, not infrequently the feverish commencement of a case of this complaint may be labelled influenza—especially if the two diseases are coincident. Undoubtedly the majority of the cases of encephalitis on which this paper is based have occurred when influenza has been conspicuous by its absence, and in none of them has a history of true influenza in the individual or his family been proved. It appears to me that the headache of influenza may be a form of influenza encephalitis.

The infectivity of the disease is apparently very low, but, as Dr. Stallybrass<sup>6</sup> has recorded, a few instances of severe infection have occurred in institutions, and, as he says, "pointed to the possibilities of the disease." During this year I have seen four instances of more than one patient in a family affected with the disease:

A young married woman was suffering from a severe form of the hyperkinetic variety; her mother complained of headache, lethargy, and weakness, accompanied by nystagmus, tremor, and paresis in the right hand; and the grandmother had headache, lethargy, nystagmus, and ptosis.

A schoolboy, aged 12, developed an acute pharyngitis, headache, and fever, followed shortly by sleepiness and delirium, when ptosis, squint, and nystagmus became evident. A few days later his mother became ill with headache, drowsiness, delirium, and nystagmus.

A man and his stepson in one house, and two women and a baby in another, were affected about the same time.

Five of these cases, though showing quite definite symptoms, were mild, and should be classed in the abortive group. They occurred in Dr. McNeil's practice. It is probable that many people suffering from the abortive type exist, but are not detected.

Most authorities think that the mode of entry of the organism is by one or other mucous membrane, most probably the mucosa of the naso-pharynx as demonstrated by Strauss. In many of my cases severe pharyngitis has been found. In one patient acute rhinitis with haemorrhage, in another severe stomatitis, in a third intense conjunctivitis, and in four diarrhoea occurred at the commencement of the illness.

Moreover, the various cases can generally be separated into an acute, subacute, or chronic variety of the disease. The acute and subacute varieties are in the great preponderance of cases that interest us here, but three at least may be classified as chronic. Wimmer has just published an interesting monograph<sup>7</sup> on chronic epidemic encephalitis, in which he truly says that "the cases may be and often

are of a chronic and insidious nature from the very beginning." In other words, chronic encephalitis may be said to be an encephalitis with non-febrile course. There is no doubt that we are now meeting with patients whose illness begins with a gradual and insidious onset, in which there is no history of fever, and which appear to be very chronic in type. Such is case No. 50, who states that her condition began gradually, without any fever for several months, and that she has been ill for two or more years. At what date an acute or subacute case with prolonged symptoms should be called chronic is sure to be a debatable question.

There seems to be no discrimination between the sexes: in these cases there have been 26 males and 36 females. The annual incidence of these patients is:

Annual Incidence.			
Year.	Cases.	Year.	Cases.
1919 ...	2	1922 ...	3
1920 ...	1	1923 ...	13
1921 ...	2	1924 ...	41

It is considered that after adult life is reached there is a diminishing liability to infection. The age incidence of these cases according to decades illustrates this pretty clearly, but at the same time it also strongly demonstrates that no age is immune: the youngest patient was 14 months, and the oldest 82 years of age.

Age Incidence in Decades.			
Age.	Cases.	Age.	Cases.
0-10 ...	4	50-60 ...	9
10-20 ...	15	60-70 ...	4
20-30 ...	14	70-80 ...	1
30-40 ...	7	80 ...	1
40-50 ...	7		

The mode of onset is very variable: frequently it is sudden.

For instance, Case 37 was struck down with headache and giddiness whilst riding a bicycle, and was found lying by the roadside in a collapsed condition. He was found to be suffering from stupor, delirium, and pyrexia. Another case, No. 61, complained of headache, went off to sleep at her work, and could not keep awake when roused. A third case, No. 18, after previous headache, became suddenly semi-conscious and appeared to be suffering from apoplexy, until it was found that he could be roused and move his limbs. Case No. 13, a woman aged 19, returned home from work and suddenly developed twitching of the legs, followed a day or two later by twitching of the arms, delirium, sleeplessness, and restlessness. In fact, she was an example of the severe hyperkinetic group. The sudden onset of two ataxic cases is mentioned later.

Other cases begin with fever, headache, and drowsiness. Thus, of 62 cases, 27 give a history of sudden onset; 15 an onset which could be described as quick (within eight days); and in 20 cases the onset was over eight days, and they are therefore classified as gradual.

Case No. 47, a woman aged 21, who had marked Parkinsonian syndrome with monotonous voice, twitching of the limbs, and tremor of the tongue, gave a history of gradual onset of many months' duration (Fig. 1).

Case No. 48, a well developed girl aged 15, complained of sore throat, feverishness, and depression for three weeks before the definite acute symptoms showed themselves.

Case No. 50, a woman aged 67, stated that her condition of lethargy, nystagmus, partial ptosis, Parkinsonian syndrome, and rigidity had taken months to develop (Fig. 2).

It is extremely difficult to classify the cases of encephalitis lethargica into different groups or types. The classification given by the American Association of Research appeals to me as best covering the ground, therefore I adopt it.

#### Clinical Types.

- I. Somnolent-ophthalmoplegic type (febrile or afebrile).
- II. The paralytic (akinetic or hypokinetic) type.
- III. The amyostatic type (Parkinson-like and cataleptic syndromes).
- IV. The hyperkinetic type (myoclonic, choreic, and epileptic forms).

FIG. 1.—Case 47.

FIG. 2.—Case 50.

- V. The psychotic type (delirious, maniacal, and depressive forms).  
 VI. The hyperalgesic type (painful forms).  
 VII. The tabetic type (Argyll Robertson pupils with loss of deep reflexes and sometimes with lancinating pains).  
 VIII. The ataxic type.  
 IX. The abortive type (formes frustes: imperfect, rudimentary, and ambulatory forms).

X. The aberrant type (intestinal, cutaneous, vagal forms, etc.).  
 Even with that grouping it is noted that individual cases may belong to two groups, either at the same time or at different periods of illness. Thus, Case 14 belonged to the hyperkinetic and ataxic groups, and Case 16 at one time to the hyperkinetic and later on to the amyostatic group.

The most common type of case has been a combination of the somnolent-ophthalmic and amyostatic types—namely, patients who suffered from lethargy or stupor, external ophthalmoplegia (of which nystagmus, ptosis, squint, and diplopia were evidence, the frequency being in the order in which they have been named), and who had the Parkinsonian syndrome more or less marked, but without tremor. Delirium in a greater or lesser degree was a noticeable feature in many of these cases. In three instances the patients were sleepless and restless at night and drowsy during the day. This condition is more frequently found in children, as in a boy aged 8—Case 54 (Fig. 3). Internal ophthalmoplegia is also sometimes present, and was the only ocular disturbance in Case 61.

One patient, Case 16, was choreic, restless, and sleepless for one week, and then changed into the type mentioned above; in the first stage her reflexes were exaggerated, and in the later stage they were diminished. Case 53 was the reverse type, as he was at first somnolent and later hyperkinetic.

Of the 62 cases, the first two, middle-aged men, were affected in 1919. Both were a combination of the paralytic and amyostatic types with Parkinson's syndrome (minus athetosis) and had cataleptic stupor well marked. Ptosis, nystagmus, and some squint with sluggish knee-jerks confirmed the diagnosis. Both patients dropped off to sleep during the examination, and showed no interest beyond asking in a monotonous whisper if they would recover. A similar case (No. 12), also a male, aged 51, was an in-patient in my wards in 1923. He lay in a deep stupor—almost coma—just swallowing liquids for several weeks, with expressionless face, dropped jaw, double ptosis, and paralysis of the left external rectus.

One other such case should be mentioned, an old gentleman aged 68 (Case 18), who had small pupils, marked ptosis, nystagmus, and lay in a cataleptic stupor from which he could only be roused by shouting. His temperature was 102°, and he gradually passed into deep coma and died. (Dr. Robertson Dunn's patient.)

Early in 1923 Group IV, the hyperkinetic type of case, became evident, in which severe restlessness, insomnia, choreic movements, rhythmical twitches of muscles and of the limbs, were pronounced symptoms. Of 17 such patients, 3 showed marked dyspnoea. One (Case 13) had respirations of 70 to 80 a minute for eleven weeks, and another

Two patients had marked myoclonic contractions of the lower jaw muscles, the rhythm of which varied from time to time, but was more or less constant except during sleep. Marked depression was found in two cases, and this quickly passed off under treatment (Cases 48 and 54—Chart 2). Mania was present in three cases only.

One patient only can be classed in Group VI—the hyperalgesic type (Case 11). This was a man, aged 33, who was suffering from the usual symptoms, but his chief complaint was shooting pains down his limbs and in his back and head. This man steadily improved, and after three months was able to leave the hospital, free from pain and convalescent.

Two remarkable cases (Nos. 14 and 41) may be classed under Group VIII, the ataxic type. Both were young women, and both had a sudden onset which included giddiness.

One, a lady stenographer, left her office on Saturday at midday, and remembered nothing further till she recovered consciousness in bed in my ward. In the meantime she had gone to the Everton football match, paid her entrance money, taken her place on the stand, and, whilst sitting there, had fallen and been picked up unconscious and brought in an ambulance to the hospital. On admission there was no evidence of injury, and it was possible to rouse her to answer questions in a slow monotonous voice. Her face was expressionless, her limbs were a little stiff with some twitching, but no real paralysis. Nystagmus and ptosis were present. She ultimately recovered and returned to her duties.

The other patient, whilst working in a garden became dizzy, had headache, squint, diplopia, and nystagmus. Later she became an in-patient and it was found that she had definite ataxia when standing with her eyes shut, and also ataxia in her arms. The other symptoms were those of Type I. (Dr. Blair's patient.)

Seven instances of Group IX have been met with, in which the symptoms have been slight and abortive. These patients were walking about, and all complained of headache, lethargy, and showed signs of nystagmus. Five of them had the Parkinson face. A few weeks' rest and treatment completed their recovery, though signs of nystagmus remained for a little time afterwards. One patient had troublesome hiccup of two weeks' duration, and thus should be classed in Group X.

The Parkinson syndrome, so characteristic and seen in nearly all of these cases of encephalitis, may be described as the typical expressionless face, the stiff expressionless gait, in which the patient moves with short steps, arms motionless by his side, head fixed straight to the front and not moving. The voice is frequently expressionless and monotonous. Athetosis was only seen in a small proportion of cases.

Delirium was present in a marked degree in 24 of the patients and was of an occupational character. For instance, a small girl, aged 15, the eldest of a large family, rolled up a towel and rocked it in her arms as though

FIG. 3.—Case 54.

CHART 1.—A, admission; P, lumbar puncture.

(Case 8) of 30 or over for fourteen weeks. It was noticeable in these two most dyspnoeic patients that a rhythmical contraction of the right arm and leg occurred with each inspiration. Several cases had retraction of the head with or without rigidity and stiffness in the limbs; in one the deep reflexes were exaggerated, and Kernig's and Babinski's signs were present. Lumbar puncture was performed on 6 of these patients. In each instance a clear colourless fluid was withdrawn under pressure, in which no micro-organisms were found, but an increase in the number of mononuclear cells (Chart 1).

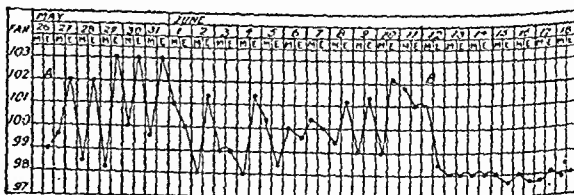

CHART 2.—Case 48.—Patient very depressed; Parkinson syndrome, nystagmus, and great sleepiness; improved on administration of sodium salicylate gr. x every three hours. Temperature dropped at B when dose was doubled, and symptoms correspondingly improved.

"nursing a baby." A joiner, also a local preacher, "held forth in prayer"; a publican fond of Llangollen was seen making the signs of traffic control, and stated that he imagined "he was in the middle of the main street of Llangollen controlling all the transport of the country, which had become congested there, and which the local police were unable to control." His wife told us that he was an ex-police sergeant, an expert on point duty. Thus, the delirium is connected with the patient's habitual or

favourite occupation, and is usually remembered by him when roused up.

One man, however, though witty and sensible when roused out of his delirium, became so violent, although the other symptoms were improving, that he had to be sent to Mill Road Infirmary, and thence to Rainhill Asylum. On his return, perfectly recovered, he did not remember a single incident of the whole of his illness after the severe occipital pain and dizziness with which it commenced.

It is remarkable how readily a patient can be roused from his delirium and remain sensible whilst spoken to. In this way it is not unlike the delirium of delirium tremens. I would suggest that delirium tremens is an encephalitis due to the toxic effect of alcohol.

Nystagmus, well or slightly marked, was found in about 90 per cent. of the cases. It was noted in many instances that the eyeball followed the finger sluggishly, and frequently returned to the centre where it was at rest. Thus a sort of nystagmoid movement was made by the patient in his effort to follow the test.

Temperature is usually found early in the severe type of case, but does not generally extend more than a week or ten days, and is not as a rule above 100° or 101°. A few instances of a more severe or prolonged fever have occurred. It is noteworthy how many—over 50 per cent.—of the patients have shown no fever; but in several, whether a temperature was present or not, the pulse rate was considerably quickened.

Four patients had marked deafness during part of their illness, two being almost totally deaf, one of whom (Case 49, aged 34) was transferred to my care by Dr. Courtenay Yorko at the Stanley Hospital. She had marked lethargy, slight nystagmus with lagging of the eyeball, and some internal strabismus. The Parkinson syndrome was present, with sleeplessness and tremor of the right hand. She has steadily though slowly improved under three months' treatment, and all the symptoms have passed away except considerable deafness. Persistent deafness of this kind is rare. In the other patients the deafness was only of short duration.

The complications which occurred were not numerous: septic sores of an intractable form were found on the fingers of one patient, sloughing bedsores in another. Herpes was noted three times, and pressure erythema twice. Nephritis was a complication in one case. Recrudescence of symptoms occurred or recurred in several patients. The symptoms were observed to become milder in each recurring attack.

#### TREATMENT.

The treatment I have found most effective is sodium salicylate 15 to 30 grains every three or four hours. In those cases where there are symptoms of insomnia and restlessness I usually add 5 to 10 grains of bromide and iodide of potassium. Influenza and acute rheumatism respond so well to salicylates that I was encouraged to hope that it would have a similar effect in encephalitis. Moreover, I treat my cases of Sydenham's chorea with this drug, with satisfactory results. Therefore, in the chorea of encephalitis, which is due to the same lesion but another virus, I felt the same drug might have the same good effect. I think the results have been satisfactory, and though signs of change of character and change of affection are noted in the convalescence of a few patients, I believe that the many disabilities and after-effects of this disease will be overcome with a persistence of treatment followed by a return to former environment and former mode of life.

As already stated, in those cases accompanied by meningeal symptoms, lumbar puncture has been performed with considerable benefit. I however look forward to the day when an antitoxic serum or some powerful vaccine will be produced from the specific organism itself.

#### RESULTS.

It is almost impossible within so short a time of the 62 patients' illness to give a strict account of their recovery. At present they can be classified as follows:

4 deaths—1 two days after admission, with coma; 1 seven days after admission, with coma; 1 seven days after admission, with toxæmia, sloughing bedsores, and septic ulcers in the mouth, after lying in bed in lodgings neglected for two weeks; 1 after five days' illness, with coma.

- 1 has neurasthenia of sixteen months' duration.
- 2 show change of affection: "affectionate father intolerant to children"; "wife's loss of affection for husband." Both of these patients are gradually regaining their normal states.
- 2 remain somewhat lethargic and inclined to loaf about instead of getting to work.
- 4 have altered character: 2 are not so active as formerly; 1 is inclined to be rude and cheeky; 1 is irritable instead of calm and placid, but is improving.
- 1 has altered handwriting—small and cramped instead of large and bold.
- 1 still remains deaf; otherwise she has recovered.
- 10 are under treatment, all improving—one a recrudescence of a former attack twelve months ago.
- 3 are chronic cases, all showing improvement: one change of character returning to normal, another showing some Parkinsonian syndrome but otherwise recovered, and a third still showing the Parkinsonian syndrome, though much less pronounced, and with less rigidity.
- 4 have recovered—any change not known.
- 30 recovery complete, including 7 abortive cases.

The duration of the illness was, with a few exceptions, two to four months.

This result, though good, shows a marked tendency for some physical defect of nervous origin to occur as a result of this disease, and, what is more serious, change of affection or character. These changes may be temporary or permanent. At present I am unable to say how many of the 24 people who have one or other of these disabilities will have a permanent alteration in character or affection. Nevertheless, I feel it is most important that the medical officers in charge of these patients should encourage them when the illness is over, and, after a prolonged change of air, to get back to their former work. The neurasthenic young lady would, I am confident, be leading a healthy normal life, attending dances and cinemas, if it were not for her devoted mother, who will not tolerate a strict nurse or carry out strict discipline. The same applies to one of the lethargic men, who will not return to work. His wife and daughter do not encourage him to get back.

I am of opinion that some of the mental changes which are considered as sequelae are due to a too lenient treatment in convalescence. For example, the alleged kleptomania in a post-encephalitic boy, who, to demonstrate his complaint when being taken before the magistrate for stealing, lifted a lamp off a police ambulance, shows rather that the lad was an expert in legal defence than a mental deficient.

It is noted that some patients for months have worn the expressionless face and walked with the stiff expressionless gait, but gradually their expressions have become natural, and they have themselves become alert. One patient who left hospital with the Parkinsonian syndrome well marked returned to the out-patients' department a few weeks later cheerful and smiling.

#### DIAGNOSIS.

In spite of the number of clinical forms met with in epidemic encephalitis there is a marked tendency to the repetition of certain characteristic types, and one type usually predominates during any particular epidemic. Thus, in 1919 and 1920 the somnolent-ophthalmic and amyostatic prevailed, and in 1923 the hyperkinetic. These types are the most common.

The occurrence in a patient of one or more of the following symptoms should make one think of the possible existence of the disease: (1) pathological drowsiness (lethargy), (2) cerebral nerve paralysis (especially ophthalmoplegia), (3) an acutely developing Parkinsonian syndrome, (4) a cataplectic state, (5) a myoclonia, (6) a chorea, (7) pupillary disturbances, (8) violent neuralgia, (9) a poliomyelitic syndrome, (10) a peculiar delirium, (11) a psychotic state, or (12) signs of meningeal irritation in times when encephalitis is epidemic.

The differential diagnosis in these cases has been: apoplexy 2, hæmorrhage in pons in 1, meningitis in 5, progressive bulbar paralysis in 1, chorea gravis in 1, delirium tremens in 3, myasthenia gravis in 2, catalepsy or epidemic stupor in 3, neurasthenia and paralysis agitans in several. The most difficult to diagnose was the case which simulated bulbar paralysis; the absence of atrophy of the tongue, together with the improvement of dysphagia and the paresis of the facial muscles, confirmed the diagnosis of encephalitis lethargica.

## PROGNOSIS.

It seems almost impossible to give any data on which to form a sound prognosis. My impression has been that the hyperkinetic is more virulent in type, and more difficult to treat, than the somnolent-ophthalmic or amyostatic type. I have seen several deeply cataleptic cases recover. On the other hand, the severe paralytic type, which simulates cerebral haemorrhage, is probably the most serious of all.

The prognosis is always grave, as noted by Faigular Buzzard<sup>2</sup> and others. My percentage of complete recoveries up to date is only 50. I would, however, strike a sanguine note, always admitting that virulent types and virulent cases do occur. One patient with mania of a most violent and acute type completely recovered in all respects, and a lad with change of character for twelve months has become normal. The Parkinsonian facies has already disappeared in over 50 per cent. of these cases.

I fear that there are many conclusions in this paper left as it were "in the air." I must plead that the disease "though old is new," and therefore it is premature to form other than hypothetical conclusions in many important details.

## THREE SIMULTANEOUS EMPYEMATA FOLLOWING PNEUMONIA.

BY

LEONARD G. J. MACKEY, M.D., Ch.B.,

HONORARY PHYSICIAN, QUEEN'S HOSPITAL, BIRMINGHAM.

On January 3rd P. S., aged 29, a bus driver, developed severe pneumonia, which, when I saw him on January 11th, had caused complete consolidation of the whole of the right lung and of the left lower lobe. The temperature became normal on January 12th, and so remained until January 21st, when it rose to 100°; three days later his medical attendant, Dr. Hubert Cox, reported that he had developed signs of empyema on both sides.

The patient was admitted to Queen's Hospital, Birmingham, on the morning of January 25th. He was cyanosed,

SKIAGRAM No. 1.

breathed rapidly and with great difficulty, and was extremely ill; the temperature was normal. He had signs of a large empyema at the left base, another over the front of the right lung, and a third at the right base. The axillary region was resonant.

Mr. Gemmill saw the patient with me and decided to operate immediately on the largest collection—namely, the left empyema—which was drained after resection of a rib; 50 ounces of thick greenish pus was removed; microscopically and by culture the pus showed pneumococci and pneumobacillus, and from it a vaccine was made and administered

SKIAGRAM No. 2.

subsequently at intervals of a few days. On January 31st the empyema at the right base was aspirated and 27 ounces of pus withdrawn.

On February 7th skiagram No. 1 was taken; it shows the tube in the left chest, the round shadow of the empyema over the front of the right lung, and the denser shadow of the collection at the right base.

On February 10th the anterior collection was aspirated, but only 7 ounces of pus obtained. Skiagram No. 2, taken on February 13th, shows how much pus remained un aspirated. By February 16th the patient's general condition had so much improved and the expansion of the left lung was so satisfactory that we decided to drain the remainder of the right basal collection, and after resection of a rib Mr. Gemmill completely evacuated it.

A few hours after the patient had returned from the operating theatre a discharge of 26 ounces of pus suddenly occurred through the tube. The anterior empyema had evacuated itself.

Thereafter the patient's progress was rapid: both lungs expanded well, the tubes were removed, and no abnormal physical signs remained. Skiagram No. 3, taken on March

SKIAGRAM No. 3.

24th, two months after admission, shows no abnormality. The patient left the hospital looking fat and well, feeling better, he said, than he had ever felt in his life.

The result was very satisfactory; whether we went the right way to get it is quite another question.

## INSULIN TREATMENT OF DIABETES IN PHTHISIS.

BY

Z. P. FERNANDEZ, B.A., M.D., D.P.H.,  
TUBERCULOSIS OFFICER, LEEDS.

CONTINENTAL and American opinions on insulin treatment of diabetes in phthisis have been conflicting. The following cases are therefore of interest. The prognosis of progressive or ulcerative phthisis with diabetes mellitus is always very grave. Leyton recorded 5 cases, of whom 4 died without responding to controlled dietetic treatment. In two cases treated with ladder diet in a sanatorium in 1918 the urine was never freed of sugar or acetone; one died of coma and the other of extreme wasting. The cases since treated with insulin are briefly as follows.

CASE I.—A girl, aged 14, with active pulmonary tuberculosis, first diagnosed in 1922. When first seen she weighed 4 st. 10 lb., and had in the urine 9 per cent. sugar with diacetic acid and acetone. Polyuria and wasting continued with ketosis on Graham's diet. X rays showed consolidation of the left upper lobe, and enlargement of the peribronchial glands with fibrosis. Early in 1923 her condition was so much worse that one felt certain that to her the advent of insulin was a real boon. In May, 1923, the fasting blood sugar was 0.18. Insulin injections were started on July 9th, at first 5 to 10 units thrice weekly. Soon the necessity for more frequent injections was recognized and financial help for the cost of the remedy obtained. In August, 1923, the urine contained 2.8 per cent. sugar; on August 21st, with two doses of 60 and 30 units of insulin, she was sugar-free for the first time. About this period she could not tolerate 5 grams of greens, and 70 to 80 units were necessary to maintain the urine sugar-free. She was able slowly to increase the carbohydrate tolerance, and by October she had a diet of 400 calories with 10 grams of carbohydrate. Her weight was now over 5 st. The blood-sugar estimate was 0.074, though previously it was as high as 0.320. In April, 1923, the lenses were swollen and cataractous, and in October Mr. Whitehead of the Leeds General Infirmary found considerable opacity in both the lenses. Her sight has now considerably improved. The physical signs of the chest are quite quiescent and her general health is very satisfactory. Early during 1924 she had fifteen or sixteen injections monthly of 10 or 20 units and a diet of 700 calories containing 16 grams of carbohydrate. With any excess of blood sugar the dose was increased. Since April, 1924, her diet consisted of 4 oz. milk, 2 oz. fish, 4 oz. meat, 4 oz. greens, 2 eggs, 3/4 oz. olive oil, 2 oz. bacon, 1/2 oz. bread, 3/4 oz. butter, and beef-teen—total calories 911, proteins being 61 1/2 grams, carbohydrates 19 grams, fats 65 1/2 grams. At present only once or twice a week she gets about 5 units of insulin.

CASE II.—Male, aged 31, height 5 ft. 2 1/2 in., weight 9 st. 5 1/2 lb. before treatment, having previously lost a stone in weight. Tuberculosis of lung was suspected by his own doctor whilst the patient was undergoing dietetic treatment for diabetes. On examination there was clinical evidence of early infiltration; this was confirmed by x rays. He had 2 per cent. sugar in the urine with acetone and diacetic acid. The blood-sugar estimation in September, 1923, was 0.258. Diet failing, 20 to 30 units of insulin were injected twice daily. The dosage had to be doubled before the urine became sugar-free with a carbohydrate tolerance of 5 grams. Two weeks after the patient only needed 5 units two or three times weekly, and remained sugar-free on a carbohydrate diet of 20 grams with proteins and fats to make up 1,250 calories. The blood sugar varied about this period from 0.122 to 0.14. Later he needed only fortnightly injections, and was able to resume work early in 1924; he continues to maintain his health. For over six months he has received no injections. He is 10 st. in weight and his lung condition is quite quiescent. He has been on a diet of over 1,360 calories; cream 2 oz., greens 12 oz., 2 eggs, fish 4 oz., meat 4 oz., bacon 2 oz., bread 1 oz., olive oil 1 oz., butter 3/4 oz., and beef-teen.

CASE III.—Male, with incipient pulmonary tuberculosis; he had 1 per cent. sugar in the urine in October, 1923, with blood sugar 0.262. On controlled diet he remained sugar-free for a time, but he began to lose weight. Insulin was therefore given through the National Health Insurance scheme. With 5 or 10 units two or three times weekly he was able to have a diet of 1,200 calories with 30 grams of carbohydrate. His chest condition is now quiescent and he does not need insulin at present.

CASE IV.—Male, suffering from chronic phthisis, with diabetic history of over a year when first seen. In October, 1923, the urine contained 3 1/2 per cent. sugar with acetone and diacetic acid; blood sugar 0.624. He was subject to neuritis. The Wassermann reaction was negative. Injections of insulin twice daily of as high a dose as 70 to 80 units failed to free the urine from sugar with practically starvation diet. He admitted he felt better with the injections. He did not continue the treatment owing to the expense and apparent failure to become sugar-free, except on one occasion. He is one of the cases with a long-standing history of diabetes in phthisis in which insulin may not effect a cure.

CASE V.—The patient in this case was a myxoedematous type of woman with chronic pulmonary tuberculosis and blood sugar

0.624. She had kept her general health on controlled diet without insulin for a year.

CASE VI.—Another patient with primary phthisis, with later diabetic onset, has also kept sugar-free for a year on controlled diet.

These cases leave no doubt that insulin has a part to play in diabetic phthisis, especially when a satisfactory diet is necessary to maintain resistance. Failure may occur with long-standing diabetes. In others diet alone may suffice for a time, and insulin may be tried if diet fails.

## TREATMENT OF EFFUSIONS IN ARTIFICIAL PNEUMOTHORAX.

BY

BERNARD HUDSON, M.D., M.R.C.P.,  
PHYSICIAN IN CHARGE, VICTORIA SANATORIUM, DAVOS PLATZ.

Effusions in artificial pneumothorax may be grouped under three headings: (1) simple, (2) serous, and (3) purulent.

*Simple Effusion.*

Simple effusion into the pleura, without fever or pain, occurs in at least 50 per cent. of the cases. It is often to be recognized by x-ray examination only, and generally gives rise to no unpleasant signs or symptoms. The patient sometimes discovers it himself, on hearing a splashing noise when he moves.

*Serous Effusion.*

Serous effusion (serous pleurisy) is a frequent complication of artificial pneumothorax, and occurs in a large number of cases. It begins with pain in the side, and fever, the temperature perhaps rising to 103° or so, and the fluid gradually accumulating. In uncomplicated cases the fever generally lasts three or four weeks, falling gradually to normal, often being reabsorbed without the need for any interference. It should not be aspirated or interfered with if this can be avoided. If, however, it becomes very large and is causing discomfort, and is not being absorbed after a long period, it may sometimes be made to disappear by sweating. The patient is sweated for one hour thrice a week by means of aspirin, hot-water bottles, and so on. Should this fail, then it would be necessary to aspirate and replace the fluid with air. In any case, whether the fluid is absorbed naturally or removed, replacement should always be performed in order to prevent re-expansion of the lung and formation of adhesions which would render the continuance of a satisfactory pneumothorax impossible. It cannot be too strongly emphasized that repeated x-ray observation is necessary.

*Purulent Effusions.*

Purulent effusions may be divided into three classes.

(a) Those due to infection with the tubercle bacilli alone—in other words, a cold abscess of the pleura—are most frequently seen in cases of severe infection; they are ushered in with pain in the side and fever, which may last some weeks. The fluid is at first clear and serous-looking; it gradually becomes more turbid, and finally develops into thick pus. After some time the temperature comes down and the patient feels, and is, in good general health. It is better not to aspirate too soon, but to wait until all active symptoms have abated. The fluid should then be drawn off in small quantities at a time, at intervals of, say, a week, and replaced with air until the chest is emptied. The effusion will probably reaccumulate, and the procedure will have to be repeated perhaps many times, but in some cases it will eventually cease to reappear.

I have at present under observation three cases of cold abscess of the pleura which have been aspirated from time to time and in which the patients have remained in excellent health, and apparently are fit and strong. This fluid in each case has now become so thick that it is impossible to get it out even with the largest-sized needle. In two of the cases it extends up to the third rib, and in one case the chest is quite full. Curiously enough, these three patients are all women of about the same age (30). I am not

interfering, in the hope that the material will organize and be converted eventually into fibrous tissue, thus causing an obliteration of the lung on that side. These three patients are all in very good general health, without cough, sputum, or fever.

(b) With purulent effusions containing tubercle bacilli and certain organisms of mixed infection the same procedure is indicated—namely, aspiration and replacement by air—and often the whole process dies down and becomes passive. I have sometimes found it very useful, instead of replacing by air, to replace by oil of gomenol (10 per cent.), which seems to act as a lubricant of the pleural cavity and prevent reaccumulation of the pus. In these cases, if the mixed secondary infection is not too virulent, the whole process may eventually settle down and not give rise to severe septic poisoning.

(c) In this class may be put those cases of acute massive secondary infection of the pleural cavity, with high fever of a septic type, shivering, sweats, rapid emaciation, and all the signs of acute septic poisoning. I have had two instances of this in the last few years.

One, in a young man of 21, was due to a perforation of the lung into what was previously a successful artificial pneumothorax cavity, which rapidly became infected. Aspiration and washing out were resorted to frequently, with no effect, and finally a rib was resected and the cavity drained. An attempt was made later to close the suppurating cavity by a plastic operation, but the patient ultimately died of an acute spread of tuberculosis in the opposite lung.

The other case was a woman aged 25. A successful pneumothorax had been done on the right side for a severe acute spreading disease in the right lung. She kept quite well, except for a serous effusion, for eighteen months, but one day her temperature suddenly rose to 104°, and the fluid rapidly became purulent. It was found to contain a pure culture of pneumococcus and no other organism. The same process was resorted to as in the last case—that is to say, aspiration, washing out, and finally drainage, and a thoracoplasty—but without effect, the patient dying a day or two after the final operation.

#### Conclusions.

Regarding the treatment of fluid, I have come to the following broad conclusions.

When dealing with a serous effusion or a serous pleurisy, do not aspirate if it can possibly be avoided. The fluid will often reabsorb by itself, or may be aided by sweating the patient. If, however, it is a very big effusion, or is causing inconvenience and discomfort, or is not showing signs of disappearing after some weeks, then it should be aspirated and replaced with air, but it is a bad thing to irritate the pleura unnecessarily by needling. A simple serous effusion may easily be turned into a purulent one by frequent aspiration. At each aspiration the fluid is seen to get more and more turbid and finally to become pus. Another important maxim is not to interfere needlessly with an acute effusion—that is to say, while the temperature remains high; it is better to wait to see if the fever will come down, as it generally does except in infective cases, and to deal if necessary with the condition when it has become passive.

When removing effusions, if there is any suspicion of the lung underneath being infected with tuberculosis, always replace with air, thereby establishing a pneumothorax. Whether the fluid is absorbed or removed, careful watch should be kept by x-ray examinations and air put in as the liquid disappears, to avoid the re-expansion of the lung and the formation of adhesions which would render the continuance of the pneumothorax an impossibility.

When dealing with purulent effusions, aspirate and replace with air when necessary. Avoid washing out if possible; it is merely irritating to the pleura and has, I believe, no beneficial effect. I have seen good results obtained by replacing in these cases with oil of gomenol (10 per cent.) instead of with air. In acute infected cases, such as the two described above, there is really nothing to be done except to drain the pleura, after attempts at aspiration and washing out, etc., have failed, and then, if possible, to continue with a plastic operation at a later date. I have seen one or two recoveries in these cases, but they are always very serious and very often fatal.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL

#### COMPLICATIONS OF LUMBAR PUNCTURE:

##### OPISTHOTONOS: OEDEMA OF SUBCUTANEOUS TISSUES.

In a series of 200 lumbar punctures, headache and pain running down the back of the legs were the commonest complications. The two following rarer sequelae which occurred in the series are worthy of notice because of the apprehension they aroused.

##### *Opisthotonos.*

*Case 1.*—D. V., a boy aged 9, with septic sores on his hands and feet, was admitted to hospital as a doubtful case of encephalitis. (This diagnosis was not verified.) A few hours after puncture he complained of intense headache, and within twenty-four hours his body was arched backwards almost to a semicircle and Kernig's sign was very definite. The boy was crying out with pain. There was, however, no rise of temperature or acceleration of the pulse rate. Within twelve hours the rigidity was passing off and the patient was free from symptoms on the fourth day.

*Case 2.*—O. I., a girl aged 7 years, was suffering from early tuberculous peritonitis. On account of drowsiness and headache she had been admitted to hospital as a case of encephalitis. Within twelve hours after lumbar puncture she developed marked nuchal rigidity, the legs stiffened, and the back was considerably arched. Her temperature rose to 99.5° F. and the pulse rate to 120. These symptoms were at their maximum in about twenty hours and had disappeared by the third day.

In these cases the opisthotonos occasioned the thought, "Have I introduced septic material and set up a meningitis?" As it happened the opisthotonos was an extreme manifestation of meningism, but the anxiety felt at the time was considerable.

##### *Oedema of the Subcutaneous Tissues.*

Levinson in his book on the cerebro-spinal fluid mentions this complication as not uncommon after repeated punctures. The case described is of interest because it occurred after the first puncture and the nature of the oedema was not at first apparent.

*Case 3.*—W. P., aged 2 years, had a history of drowsiness, vomiting, and diarrhoea, and was admitted to hospital certified encephalitis. (This diagnosis was afterwards altered to gastroenteritis.) The day following lumbar puncture a fluctuant swelling, the size of half an orange and with a fairly well defined margin, was noticed between the scapulae. There was no obvious oedema at the site of puncture. The child had no constitutional symptoms. A needle was inserted, with negative result. On the second day after puncture an oedematous area extended down the back and joined the swelling between the scapulae to another similar but smaller swelling over the site of puncture. Only then was it recognized that the oedema was due to a considerable leakage of cerebro-spinal fluid. The swelling subsided in four days and the child did not appear to suffer any ill effects.

JAMES L. HALLIDAY, M.D.  
(From Ruchill Fever Hospital, Glasgow.)

#### ACUTE CALCULOUS CHOLECYSTITIS IN A GIRL OF FIFTEEN.

I WOULD like to add the following to the interesting series of cases of gall stones in young subjects recently appearing in the JOURNAL.

I. C., aged 15 years, was seen with Dr. Hendrie Kirk on May 20th, 1920, with acute abdominal condition of four days' duration. Illness began with pyrexia, pain in the back, and sickness. On the third day there was considerable vomiting, and on the fourth day rigidity was noticed in the upper part of the right rectus, and persisted even after an opiate had been given. Tenderness was present, the maximum being at or just above McBurney's point. The case was thought to be one of acute appendicitis, and she was admitted to the Western Infirmary for operation.

An incision made through the right rectus just below the level of the umbilicus exposed a swollen and inflamed rounded mass below the edge of the liver, and glued to the surrounding viscera by recent fibrinous exudate. Dark green bile was drawn off by hypodermic syringe. The mass was then incised, and proved to be an acutely inflamed gall bladder containing twenty-six calculi and a quantity of debris and mucus. The calculi were pale, soft, and friable, spherical in outline, and of average diameter of 5-7 mm. They possessed a raspberry-like surface, and each seemed to be formed of a conglomeration of smaller spheres. The wall of the gall bladder was nearly a quarter of an inch thick, and the mucous membrane was

oedematous and velvety. Drainage was employed and recovery was uneventful. The bile which had been aspirated failed to show organisms in film or culture.

G. H. EMMINGTON, M.D., D.Sc.,  
Surgeon, Western Infirmary, Glasgow.

### HEREDITARY JAUNDICE.

HEREDITARY icterus is a condition which has long been recognized by the profession, but I cannot find a reference to a case where the sex of the child appears to play a part. The following case shows a striking susceptibility on the part of the female children, while the boys were more or less unaffected.

The mother, aged 41, has been subject to "fits"—presumably fainting fits—more or less all her life, but especially while she was pregnant. Her father died at a comparatively early age of tuberculosis. Her mother also "took fits." She (the patient) had several sisters who died in infancy from jaundice and convulsions.

The patient's own family has been as follows (the mother's age at the birth of each child is given in parentheses):

1. Boy; healthy. (18 years.)
2. Boy; tuberculous. Has had one or two fits. (24 years.)
3. Boy; healthy. (27 years.)
4. Boy; healthy. (30 years.)
5. Miscarriage at three months.
6. Girl; died when 23 hours old—jaundice and convulsions. (33 years.)
- 7 and 8. Twin girls. One died when 3 days old, the other when 7 days old; both had jaundice and convulsions. (3½ years.)
9. Boy (premature—8 months); healthy. (36 years.)
10. Girl; died when 7 days old—jaundice and convulsions. (41 years.)

Glaister recorded in 1879 (*Lancet*, March) a case in which a woman had 8 children, 6 of whom died of jaundice shortly after birth, but the above sex preference does not appear to have shown itself. The cause of the condition is rather obscure, no particular changes being found in liver or bile ducts, but it would be interesting to know if others have observed this curious selection of female children.

The strong tuberculous taint may play an important part; but, as I was unable to make a *post-mortem* examination in the case which I saw recently, I could not determine the state of the liver and bile passages.

Leadgate, co. Durham.

W. MURRAY TAYLOR.

## British Medical Association.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### OXFORD DIVISION.

A MEETING of the Oxford Division was held at the Radcliffe Infirmary on May 27th; in the absence of the President (Dr. Neill) Mr. R. H. A. WHITELOCKE was in the chair.

#### Vesical Calculus.

Mr. W. W. WAGSTAFFE read notes of a patient, aged 69, from whose bladder he had removed a mulberry type of calculus weighing 6 ounces.

This patient was admitted to hospital on April 29th, with a history of acute retention; he had had difficulty and frequency of micturition for five years, but had never been catheterized, and apart from the difficulty of micturition had had no pain. His mental condition was not very clear, so that it was not possible to get a very good history from him. His bladder was found to be acutely distended, and 32 ounces of urine was withdrawn by a gum elastic catheter, which passed quite easily. The rectal examination showed an enlarged prostate and a hard nobby mass in connexion with it. The blood urea was 220 mg. per 100 c.cm. On May 1st the bladder was opened and a large stone of the mulberry type was removed, which weighed 6 ounces. The prostate showed some enlargement of the middle lobe; as a whole it was fairly soft. The bladder was drained. Since the operation the patient improved at first, but gradually lost ground, sank, and died three and a half weeks after admission; no necropsy was permitted. The terminal condition was one of suppression of urine.

It was very exceptional to find such a large mulberry stone with no phosphatic concretions on it. The hard, nobby mass felt by the rectum was undoubtedly the stone lying in the base of the bladder, but, since the prostate was also enlarged, it was difficult to dissociate the two conditions, and the existence of the stone was not suspected before the operation. The history was entirely suggestive of prostatic enlargement and not of vesical calculus.

Another point of interest was the high blood urea, which gave a very good indication of the severity of the clinical condition, being correlated with anorexia, dry tongue, and, frequently, a confused mental condition. The blood urea test was very valuable as regards the suitability for operation of all urinary cases.

#### Typhlitis.

Mr. Wagstaffe then gave an account of a patient who was found at an operation to be suffering from the rare condition of typhlitis.

A man, aged 50, was admitted to hospital with a history of vomiting and twenty-four hours' acute pain in the right iliac fossa. For one week previously he had had slight pain in the right iliac fossa, but had continued at work. On examination he showed an indefinite mass in the right iliac fossa, but was rather tender in both right and left iliac fossae; there was some resistance in the right iliac fossa but no tenderness in the loin. His temperature was 100° and pulse 100. The diagnosis made was appendicitis, and an operation was immediately performed. On exploring the peritoneum through a Battle incision some free fluid was seen. The appendix was found to be long but not adherent, slightly thickened, but not acutely inflamed; it was removed, but was obviously not the original condition which had caused his acute illness. On further examination the caecum was found to be acutely inflamed, especially the posterior part, and parts of it were almost gangrenous. It resembled a caecum which had been in an intussusception, except that there was no trace of inflammation on the small intestine; the caecum and the ascending colon were not sufficiently mobile for this to have been the case. The caecum was thoroughly explored; no perforation was found, and the rest of the gut was also explored; nothing else abnormal was found. The pathological report was that the appendix was the seat of chronic inflammation, while the caecum was acutely inflamed. A soft rubber drain was inserted to the posterior aspect of the caecum through the operation incision; the wound healed perfectly, but there was considerable distension and constipation, which was overcome by appropriate treatment.

Inflammation of the caecum apart from inflammation of the appendix was described in the textbooks as not occurring, and a fairly extensive search of the literature had revealed no similar case. Before the publication of Fitz's paper on appendicitis in 1886 the condition of the caecum and appendix in appendicitis was not properly understood. The importance of the appendix was not appreciated and the importance of the caecum was over-estimated; but pathological conditions had not been in the least appreciated, and there was great confusion of thought. The reason of this was that these cases were rare, and they were only investigated after death, when the condition in the peritoneum cavity was that of general acute suppuration, so that it was difficult to identify the primary cause. In 1885 Hector Mackenzie, writing in the *St. Thomas's Hospital Reports*, said: "Perforation of the vermiform appendix is a disease raro in its occurrence, obscuro in its symptoms . . . and from this rarity and obscurity it is not always that a physician recognizes it and is able to differentiate it from other diseases." A search through the records of St. Thomas's Hospital showed that the first case of appendicitis recognized in the hospital was reported in 1889. It was not true, probably, that the diagnosis was missed in a large number of cases, because the records did not show a large number of patients dying from acute peritonitis or abdominal abscess. One or two a year only were found, and it was very striking, when comparing the results for, say, 1889 with those of the last year published, 1922, that there were actually 215 cases of acute appendicitis operated on at St. Thomas's. Secondly, the first account found by Mr. Wagstaffe of this condition of inflammation of the right iliac fossa was in Dupuytren's *Leçons Orales* (date 1833). Dupuytren gave a long account of abscess in the right iliac fossa, but this was not very helpful, since he built up a very fine theory on extremely loose observation. The theory which held ground for a long time was that the caecum was the site of origin of all these abscesses in the right iliac fossa. It was not until the work of Fitz, in 1886, which gave a rational and clear account of appendicitis, that this caecal theory was finally overthrown. But such a case as this showed that there was after all something in the caecal theory.

#### Gall-bladder Surgery.

Mr. DODDS-PARKER read a paper on some aspects of gall-bladder surgery, in which he advocated cholecystectomy rather than cholecystotomy for gall stones. The advantages of the former were: (1) that it removed the site of

gall-stone formation; (2) that it removed the focus of infection, which was otherwise liable to persist; (3) that it prevented many cases of biliary fistula; and (4) that it eliminated the risk of the subsequent development of cancer. Since 1907 Mr. Dodds-Parker had removed the gall bladder in 90 cases with only 3 deaths. One of these was from septic pneumonia, another from multiple abscess of liver, and the third from delirium tremens. He performed cholecystectomy in cases of acute septic gall bladder with gall stones and in chronic inflammation with gall stones, where the gall bladder might be either enlarged or small and contracted, with many adhesions, which offered considerable difficulties at times. In addition to the complications which arose from adhesions, the presence of jaundice added to the gravity of the case, since then the general condition of the patient was usually worse. Mr. Dodds-Parker described three cases of gall stones he had met with in undergraduates. Mr. R. H. A. WHITELOCKE described two cases in which he had performed cholecystendysis with a satisfactory sequel in each. Dr. COLLIER related a case in which typhoid bacilli had been found in the excreted contents of the gall bladder (duodenal tube) as well as in the gall stones which were subsequently removed. The attack of enteric fever had occurred twenty-five years previously. It was probable that the case would be recorded more fully at a later date.

### ULSTER BRANCH.

The annual meeting of the Ulster Branch was held in the King Edward Hall of the Royal Victoria Hospital, Belfast; the professional part consisted in the exhibition of rare and interesting cases, pathological and bacteriological specimens, instruments, and photographs.

Dr. Monnow showed a case of muscular dystrophy, and, as a contrast, one of amyotrophic lateral sclerosis; Dr. T. HOUSTON, some experiments with leucocytes; Professor THOMSON, a chondroma of the brain; Dr. BOYD CAMPBELL, slides and specimens from a case of myeloblastic anaemia; Mr. MITCHELL, a case of pressure paraplegia treated by Albee's spinal graft.

Professor FULLERTON showed unusual varieties of club-foot, polypoid projection in the posterior urethra, plating of re-fractured femur, chondroma of the hand, malignant growth of the bladder treated by diathermy, also radiograms illustrating pyelography and cystography. Mr. HOWARD STEVENSON showed medullary carcinoma of breast, and, with Dr. RANKIN, some cases of carcinoma of the tongue and soft palate treated by fulguration.

Dr. J. A. SMYTH showed six cases of diabetes under insulin treatment. One of these, a male, aged 34, had a duodenal stenosis, and the carbohydrate tolerance improved greatly after successful operation; no insulin had now been administered for three years. Another received 500 units of insulin daily during an attack of pneumonia in which she had excessive acidosis; a dose every four hours was given. Professor WILSON demonstrated a new method of counting the red cells, which did away with the use of a haemocytometer.

Mr. S. T. IRWIN and Mr. R. J. MCCONNELL showed a series of club-feet treated by adhesive plaster; three cases of slipped epiphysis of femur; a series of radiograms of duodenal and gastric ulcers; a case of arthrodesis of shoulder-joint for flail-joint due to infantile paralysis; a case of ramisection for spastic diplegia; and a stereoscopic radiogram of a rare fracture of the acetabulum.

Mr. P. T. CRYMBLE showed a case of resection of two-thirds of stomach for hour-glass contraction due to ulcer, together with a specimen and radiogram. He exhibited also the instruments for reduction and fixation of a fracture by steel ribbons and plate, with illustrative radiograms. Mr. H. P. HALL's exhibits referred to plating for spiral fracture of femur, plastic repair of hypospadias, perforated duodenal ulcer, compound depressed fracture of skull, and reconstruction of the nose following rodent ulcer.

Mr. H. P. MALCOLM showed seven very successful end-results of the treatment of hip-joint disease from the open-air home at Greymount, a case of chronic abscess of the frontal bone, a case of lymphangioma of the submaxillary region, from which a clear serum could be drawn off which clotted at once.

Professor McILWAINE showed a case of infantilism in a boy, aged 17 years, with enlarged spleen and hydrothorax, which had undergone repeated aspiration; the Wassermann test was positive, and under antisyphilitic treatment the patient had grown two inches, and increased from 4 st. 11 lb. in weight to 6 st. 1 lb.

## Reports of Societies.

### MALIGNANT DISEASE OF THE PHARYNX AND LARYNX.

THE summer meeting of the Section of Laryngology of the Royal Society of Medicine was held on June 5th, with the President, Dr. A. LOGAN TURNER, in the chair. Before the proceedings began the President welcomed a number of distinguished guests, including Dr. Tapia of Madrid, Professor Burger of Amsterdam, Dr. Charles Mayo of Rochester, Minnesota, and Dr. Graham Brown of Brisbane.

#### *Big Pharyngostomes as an Accident in Laryngectomy.*

Dr. TAPIA read a paper, in French, on the big pharyngostomes as an accident in laryngectomy. He had performed 151 laryngectomies, with a post-operative mortality of about 5 per cent. It was impossible to leave a patient with the mutilation that radical removal of malignant tumours from the region of the pharynx and larynx demanded. Dr. Tapia showed how large pharyngostomes could be avoided. Pre-operative preparation of the mouth and nose, with a view to avoiding sepsis, was most important; septic teeth and septic tonsils, if present, should be removed some time before the operation. He described his method of closing pharyngostomes when they had resulted. The object of the second operation was to make the life of the patient more worth living, to help him to speak and to swallow.

Mr. WILFRED TROTTER said that the object of plastic procedures in the treatment of malignant disease in the pharynx and larynx was not only to offer the patient a reasonable chance of maintaining his powers of speech and swallowing, but it was extremely important to leave the patient, immediately after the operation, without any extensive raw surfaces in communication with the pharynx, in which infection could occur, with the very serious dangers of cellulitis in the neck and secondary haemorrhage. For instance, with such a bugbear of surgery as post-ericoid carcinoma one could have the patient, in a reasonably favourable case, speaking and swallowing normally within six weeks of the primary operation. The surgeon must know beforehand what kind of tumour he had to deal with, and it was surprising how exact and precise one could be on that point. He asserted that one could not do good plastic work in the pharynx and larynx unless one could secure a reasonable amount of asepsis. Sepsis meant, if the patient survived, scarring; and there was nothing more upsetting to the results of plastic surgery in the pharynx than a great deal of scarring.

Mr. LIONEL COLLEDGE recounted a case which illustrated the importance of removing the teeth before operating for malignant disease of the larynx. The patient had a recurrence of cancer of the larynx, and after laryngectomy the wound broke down and septic bronchitis resulted, although some septic teeth had been removed before the operation. After removing all the remaining teeth the wound healed up.

Sir STCLAIR THOMSON said that the textbook descriptions of laryngectomy, or similar operation gave the impression that the wound was stitched up and it healed like a razor cut on the face. Frequently, however, it was not so. Before the war, when less was known about plastic surgery than now, one had to wait and pack; he had sometimes seen three months occupied in closing.

Sir JAMES DUNDAS-GRANT said that he had been greatly impressed, when seeing Mr. Wilfred Trotter doing a lateral pharyngectomy, to notice that he stitched the deeper parts, and only partially stitched the superficial parts, thus leaving a space for the escape of any secretions and for packing; the result was eminently satisfactory.

#### *The Case of Diseased Conditions of the Pharynx, Larynx, and Mouth.*

Dr. CHARLES MAYO said that in thinking of infection by a particular kind of organism it was well to inquire also what was its chemical composition and its place in the

world. Warts and papillomatosis of the mouth, vocal cords, bladder, rectum, and other parts, if irritated and subjected to ineffectual attempts at removal, became liable to the development of malignancy. More attention should be paid to the mouth region in the somnolent form of encephalitis; in this disease there was a redness of the pharynx, and it was very likely that the mucous membrane of this region was suitable to the causal organism. He believed that in his father's day ordinary clinical observation was carried to a higher degree of perfection than in these days of elaborate laboratory and other aids. Sometimes to-day the clinical examination of a patient by a doctor omitted the examination of the tongue. There had recently been, in America, a tremendous increase in heart disease and in infections, and *post-mortem* examinations showed that much of this was due to sepsis from the teeth. The killing of tooth nerves and filling and crowning by the dentist prevented the patient from feeling the danger signal of pain when he had actually a septic focus in his mouth. In middle and later life people had troubles which were not purely due to infection, but to alteration in the blood found at those periods. He would like x-ray pictures to be taken of teeth and jaws, not only to see the amount of infection, but also to find out how Nature was dealing with the calcium in infected areas. There were periods of life at which they were resistant to certain infections, and then when a break came a change was seen in a person's colour and appearance; the leucocytes of such a person would probably be found to be down anything from 75 to 55 per cent. Inheritance was really a question of the degree of resistance, and a study of family history supplied an inkling of what had specially to be contended against.

#### *Speech after Laryngectomy.*

Professor BENGER read a paper on the means of restoring some measure of speech to patients whose larynx had been completely removed. He brought with him a patient on whom he had performed this operation, in order that the meeting might judge the measure of success, which was very remarkable, of the means employed. He formed a pseudo-glottis at the mouth of the oesophagus, so that during quiet respiration the mouth of the oesophagus was always wide open.

Mr. LIONEL COLLEDGE demonstrated the McKenty-Western artificial larynx, and showed two patients who were using it successfully. In many respects this artificial larynx resembled that of Dr. Tapia, except that the chamber was a little larger in his, and there was also a screen by which the tension of the membrane could be adjusted.

Dr. GRAHAM BROWN exhibited an artificial larynx, the chief advantage of which over others was that it overcame the escape of saliva which usually occurred around the opening of the artificial larynx.

Dr. TAPIA also demonstrated his well known apparatus employed for the same purpose. He said that the ideal, however, was to get the patient to speak without the aid of any apparatus.

Sir JAMES DUNDAS-GRANT showed a patient, a young woman, whose larynx he had removed two years ago, and whose articulation was so clear that she was able to do her own shopping.

#### *Tracheotomy in Tuberculous Laryngitis.*

Dr. T. RICHIE RONGER said that the root treatment of tuberculous disease in any part of the body was to place the affected parts in a state of physiological rest, as far as possible. Records showed that the normal lung was not prejudiced by the wearing of a tracheotomy tube. He gave details of four cases in which he had carried out tracheotomy in tuberculous laryngitis.

Sir JAMES DUNDAS-GRANT thought that in the cases described tracheotomy was fully justified.

Mr. E. D. D. DAVIS said that he always tried to avoid tracheotomy in such cases, because the tracheotomy wound became very septic, and also because such patients had a good deal of coughing, which did most damage to the larynx. Sir STCLAIR THOMSON said that tracheotomy as a curative measure was seldom called for in tuberculosis. Dr. P. WATSON-WILLIAMS and Dr. DOUGLAS GUTHRIE also

#### *Intranasal Daercycystostomy.*

Mr. J. S. FRASER read a short paper on intranasal daercycystostomy, and described the operation in detail. No after-treatment was necessary, and the average stay in hospital was only four days. The procedure was much more effective than dilatation of the tear passages or excision of the tear sac. The paper was discussed by Mr. J. B. HORGAN, Mr. LAWSON WHALE, Mr. A. J. M. WRIGHT, Mr. W. J. HARRISON, Mr. E. D. D. DAVIS, and Dr. GRAHAM BROWN.

#### *The Sinus Condition in Encephalitis Lethargica.*

Mr. A. LOWNDES YATES said that in the cases investigated the pneumococcus or Friedländer's bacillus was most commonly found, and in all the patients there was rhinitis and sinusitis, usually affecting the posterior group of sinuses. Mucus was absent, and the membrane seemed to have lost its function. There were comparatively few sufferers from the disease, but many carriers.

### MANGANESE AND ANTIBODY PRODUCTION.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on May 15th, the President, Professor J. T. WHELAN, in the chair, Dr. HORGAN read a paper on the non-specific stimulation of antibodies (effect of manganese on agglutinins), and showed lantern slides.

Dr. HORGAN stated that each of a number of rabbits had been given one dose of typhoid vaccine intravenously, and subsequently intravenous injections of manganese chloride after various intervals of time. It was found that manganese did not prevent the normal fall from the primary peak of the agglutination titre. In three out of six animals the metal caused a rise in titre. The animals which were positive all showed well marked primary peaks, a fact which might suggest a relation between the power of the animal to produce antibodies and the powers of response to the stimulation of manganese.

Professor J. W. BIGGER said that the definite opinion of the Danish school was that manganese increased the antibody content. Experiments in England indicated that manganese did not increase the antibody content; Dr. HORGAN had obtained partial positive results. This difference in the results obtained was probably due to the difference in the rabbits in the different countries. No experimental evidence of the efficiency of colloidal preparations had ever been produced. Apparently manganese greatly stimulated the production of antibodies but did not itself produce antibodies. He thought that manganese might do good in cases where the patients had shown some signs of an active immunity, but not in cases where there was a total absence of immunity. He did not think that the results obtained by the use of colloidal preparations would be any better than those obtained by Wright's immuno-transfusion.

Dr. G. FITZGERON referred to the results obtained in cases which had been treated by injections of manganese chloride for sepsis. He agreed with Professor Bigger that this treatment could hardly be looked upon as being one of the most effective, although in some cases patients responded well to it. He thought it probable, however, that in these cases any cure was due to the patients being able to resist bacterial invasion.

Professor J. A. SCOTT thought the elements which produced blood clots were very much the same as antibodies. He thought it should be remembered there were different types of blood, and that in some rabbits manganese might produce changes, while in others it would not, because the types of blood were different.

Dr. V. M. SYNGE referred to the beneficial effect, in cases of boils, of the use of colloidal manganese. Sometimes patients in whom an autogenous vaccine had failed would improve rapidly after a few injections of colloidal manganese, while, on the other hand, some patients who had become better after an autogenous vaccine had not improved after colloidal manganese injections. This fact seemed to him to be rather contrary to the conclusions of Dr. HORGAN.

## Kretschmer.

### PHYSIQUE AND CHARACTER.

DR. E. KRETSCHEMER'S contributions to psychiatry are practically unknown in this country, and we therefore welcome a translation of his notable work, *Körperbau und Charakter, under the English title Physique and Character: An Investigation of the Nature of Constitution and of the Theory of Temperament*.<sup>1</sup> The problem considered is the relation between human form and human nature. The poet, the novelist who takes such pains to describe the physical appearance of his characters, and the man-in-the-street, all intuitively recognize some general correlation between psychic type and physical constitution. Dr. Kretschmer, basing his views, not upon vague impressions and general reflections, but upon exact anthropological investigations and the study of psychological types, has arrived at a position which gives some support to the popular view. Briefly, he discovers statistical relational frequencies between certain forms of physique and certain psychic types. The author, who impresses the reader as not only an eminent psychiatrist but as an attractive writer, commences his work with the following quotation, which provides a fitting introduction to his thesis:

Caesar: Let me have men about me that are fat;  
Sleek-headed men, and such as sleep o' nights;  
Yond Cassius has a lean and hungry look;  
He thinks too much: such men are dangerous.  
Anthony: Fear him not, Caesar; he is not dangerous;  
He is a noble Roman, and well given.  
Caesar: Would he were fatter! . . .

The fat men preferred by Caesar correspond to the cycloid or manic-depressive psychic dispositions which the author finds shows a clear biological affinity with a body-build which he describes under the term *pyknic*. The "Cassius" types, on the other hand, whom Caesar distrusted correspond to the schizophrenic psychic dispositions which, according to Kretschmer, have a clear biological affinity with a body-build which he describes as of the *asthenic* and *athletic* types, together with certain *dysplastics*. We do not, of course, wish to convey the impression that the distinction between the various types of physique is based upon mere fatness and leanness; actually it is based upon detailed researches of the physique, skeletal and muscular systems, the face and skull, the hair, skin, complexion, and ductless glands. Dr. Kretschmer holds that diagnosis by means of body-build is as vast and complicated a region as organic neurology, and that it calls for the accurate observation and co-operation of numerous observers. He modestly describes this book as a preliminary canter, and obviously confirmation by others working on a scheme similar to that outlined in his text is needed. In a general way it may be said, however, that his formulations will be recognized by most psychiatrists to be approximately true since they are based upon facts already known to experienced observers of abnormal psychic types. Particularly would we call attention to the tendency to dysplastic forms of growth in schizophrenia (dementia praecox). A superficial survey of the physique of the young people who come into asylums suffering from dementia praecox reveals a striking incidence amongst them of inhibited physical development. They are obviously inferior biological types, and exhibit, in particular, marked deviations from the normal sexual characteristics. In a chapter dealing with this subject the author emphasizes the fact that variations in physique in a dysgenital direction, and indeed of a eunuchoid as well as of an infantile nature, are relatively common among schizophrenes. This leads us, of course, to think of the work of Mott in this country, to which the author refers only in a footnote. Dr. Kretschmer warns us, as Mott has done, that we must beware of setting out the possible causal functioning of the generative glands in schizophrenic disease in the form of a simple massive, monosymptomatic disturbance of function.

<sup>1</sup> *Physique and Character: An Investigation of the Nature of Constitution and of the Theory of Temperament*. By E. Kretschmer. Translated from the second, revised and enlarged edition by W. J. H. Sperry, B.A. Harcourt, Brace and Co., Inc., 1925. (Demy 8vo, pp. xiv + 266; 32 plates. 12s. net.)

Castration of a soundly constituted man has, as is well known, no psycho-pathological results of a schizophrenic nature. If an endocrine etiology be accepted as probable in schizophrenia, we must regard it as a very tangled chemical relation between the brain and the glandular complex, in the etiology of which the generative glands are very obvious.

Such researches must be regarded as of fundamental importance since they tend to place psychiatry upon a firm biological foundation. In commenting in this JOURNAL of December 6th, 1919, on Mott's researches into the pathology of dementia praecox, attention was drawn to the fact that the regressive biological changes he described served to explain the clinical phenomena and psychic peculiarities of the subjects of this disorder. Dr. Kretschmer has an interesting chapter on this, in which he correlates the morphological findings in dementia praecox with its clinical manifestations, drawing particular attention to the fact that the disease is usually associated with inadequate sexual functioning. In seeking to correlate bodily habitus with inborn temperament it has to be borne in mind, as the author reminds us, that the factors responsible for the build and character in any given case are not entirely dependent on the inherited psycho-physical constitution. On the one hand, the body-build is influenced by occupation, mode of life, biological epochs, and nutrition; on the other, the personality depends, not only upon the inborn temperament, but upon all the experiences to which an individual is subjected from the day of his birth. It still remains, however, that there is something in the physical form and in the psychic reaction which is purely inherent and unalterable by circumstances or environment, and this is the problem considered by the author.

In the second part of the volume Dr. Kretschmer deals with the psychological aspects of his subject, and it may here be mentioned that his cyclothymic corresponds closely to Jung's extrovert, and his schizothymic to the latter's introvert. These two biological types include the great mass of healthy individuals as well as the corresponding psychotics scattered among them. Dr. Kretschmer would have us look on the biogenetic psychoses as variations from the biologically normal. He suggests that we should not look on certain types of personality as psychopathic abortive forms of certain psychoses, but vice versa, certain psychoses should figure as caricatures of certain normal types of personality. On this theory the psychoses are only uncommon exaggerated editions of large groups of healthy constitutions. In his study of temperaments, the author reveals himself a connoisseur of the subtle variations of human nature, and also as the possessor of a gift of character delineation which a novelist might well envy. The following picturesque description of the schizoid temperament could hardly be improved upon (p. 146):

"Schizoid men have a surface and a depth. Cuttishly brutal, dull and sulky, like a mollusc without a shell—that is the surface. Or else the surface is just nothing; we see a man who stands in our way like a question mark, we feel that we are in contact with something flavourless, boring, and yet with a certain problematic taste about it. What is there in the deep behind all these masks? Perhaps there is nothing, dark hollow-eyed nothing-affective anaemia. Behind an ever silent facade, which twitches uncertainly with every expiring whim—nothing but broken pieces, black rubbish heaps, yawning emotional emptiness, or the cold breath of an arctic soullessness. But from the facade we cannot see what lurks behind. Many schizoid folk are like Roman houses and villas, which have closed their shutters against the rays of the burning sun; perhaps in the subdued interior light there are festivities. . . . A young man dreams away the lovely days of his youth. He is so clumsy and loutish that one could shake him. If he is set upon a horse he falls off at once. He smiles in an embarrassed way, rather ironically. He says nothing. One day there appears a volume of poetry he has written; exquisite feeling for nature; and every blow that some fat lout has given him is passed by is moulded into an inner tragedy, and the polished rhythms flow on full of quiet."

Or, in less sombre vein, the author makes the polite sensitive man live before us (p. 214):

"His whole nervous system is tender; he flies from all that is common; he takes an aesthetic interest in tea, and is affected by the scent of hay. In society he prefers a carefully chosen circle. *Odii profanum vulgus*. Painful care is dispensed on tending the body. Such men may easily be upset by a bad ironing crease; they cannot get over aesthetic details, and they have a tendency to little vanities, and society pedantries. They like to cultivate their own personalities, and observe their own psychic fineness."

The author's investigations take him into the fields of family character and heredity, and a study of the book as a whole encourages the reader to believe that the problems of psychic life must not only be approached from a purely psychological aspect, but also from the point of view of natural history and biology. We can thoroughly commend this volume to those who are interested in psychiatry and its allied sciences.

### THE PRACTICE OF GYNAECOLOGY.

PROFESSOR JELLYTT has provided the profession with "the long and the short of it" in regard to both midwifery and gynaecology, and each of his volumes, whether full treatises or short textbooks, has met with a degree of success which is the best testimony to its worth. The fifth edition of the "long" *Practice of Gynaecology* has just appeared, and presents a number of alterations and additions which have brought it up to date. Thus, the comparatively recent work on gas inflation of the peritoneal cavity receives adequate notice, while the work of Sampson and others on implantation adenomata of endometrial origin is well summarized. The connexion between the menstrual function and the ductless glands is more fully explored than in previous editions, and the author evidently leans to the side of scepticism as to endocrine therapy in disorders of menstruation. In the section dealing with endometrial implantations in the pelvis he expresses the view, with which we are in entire agreement, that there is need for much more experience of the results of conservative treatment. The indiscriminate performance of radical operations in such cases is to be deprecated until our knowledge and experience are considerably increased. New chapters have been added on sterility and on the general principles governing gynaecological operations. The latter gives very lucid and convincing expression to truths and principles which ought to be the guide of everyone who essays to operate on the female pelvic organs.

Dr. Walter Stevenson has contributed a very full, but at the same time succinct, discussion of the use of x rays and radium in gynaecology, and Dr. R. J. Rowlette is responsible for an optimistic chapter upon vaccine treatment. The chapters on operative methods are clearly written and well illustrated, and our only criticism is that it seems unnecessary to describe an operation at some length and then state that such a method ought never to be followed. This is a somewhat cumbersome way of teaching advanced students, but, of course, it is to be remembered that this is the "long" textbook, and that the author has also published a "short" one for those who prefer brevity.

Completeness and up-to-dateness are the main impressions which this edition leaves upon us, and the book can be recommended as an admirable textbook on the subject. We offer our congratulations to the author and also to the publishers.

### PALMER OF RUGELEY.

DR. GEORGE FLETCHER's book on *The Life and Career of Dr. William Palmer of Rugeley* differs from those accounts of remarkable trials of which some have been lately reviewed in these columns. Instead of a formal and sometimes wearisome report of the evidence, we have here the outcome of almost a lifetime's study of this criminal and his doings, in which the author enjoyed certain personal advantages as a resident in the neighbourhood. He tells us that his first visit of inquiry was made only three years after the trial of Palmer for murder, and his last five years ago, so that this book is the result of more than sixty years' inquiry and study.

Our profession is justly proud of many members who have distinguished themselves and adorned their calling by their virtues and their talents. On the other hand, it has to deplore the undeniable fact that, like other callings, it has fostered some unspeakable villains such as the poisoners Palmer, Pritchard, and Lamson. Of these the subject of

this biography was *facile princeps*, for it appears probable that he was guilty of the murder of at least a dozen persons, among whom were his own children, legitimate and illegitimate, and his wife, his mother-in-law, and brother; yet it was for none of these that he was tried and found guilty, but for the murder of his friend Cook, apparently committed in order to facilitate and conceal his thefts. Dr. Fletcher claims that, although a number of books have appeared on this subject, his is the first to deal fully with Palmer's life and career, and we think that this claim is justified and that no other work probably shows so clearly how long the murderer's career of crime had been and how extraordinarily unsuspicious and gullible were his neighbours and fellow practitioners. For this is not a case of a man of apparent respectability being at last detected in crime. Palmer had for long been leading a notoriously dissolute life, neglecting such practice as he once had, and associating with disreputable racing men and other shady characters.

The most astonishing aspect of the case is the medical, in which the ineptitude of practically all the medical men concerned, before the coroner's jury returned their verdict, is almost incredible. Not a shade of doubt of their good faith and intention has ever been suggested, yet had they been in collusion with Palmer and accomplices before the fact they could hardly have played into his hands more completely. Not only the aged Dr. Bamford, who was probably past his work, but younger practitioners of good repute showed themselves astonishingly ready to accept the poisoner's suggestions as to the cause of death and to sign certificates accordingly. The scene at the *post-mortem* examination of Cook has often been described, and is indeed a commonplace in all books on forensic medicine and toxicology; yet no matter how often its description is read, the amazement of the reader at such a fiasco is unabated. It still remains inexplicable that the conduct of Palmer on that occasion did not arouse the very strongest suspicions in the minds of the spectators. Yet it remained for the stepfather of the murdered man to insist on an inquiry, on the inquest, and on probing the matter to the bottom.

Nearly all the great names of the Bench and Bar and of the medical profession of the day appear in the records of the trial, and one of the great benefactors of medical charities, Mr. George Herring, then a betting commission agent, was a witness for the prosecution. The case occasioned the passing of what is popularly known as "Palmer's Act," under which the venue of a criminal trial may be changed when popular feeling seems likely to jeopardize the course of justice. Another innovation was the starting of a hunger strike by Palmer when in prison, in which, less determined than the women suffragists, he did not persist when threatened with the stomach pump.

It is difficult, nearly seventy years later, to realize the tremendous excitement caused by this trial throughout the country. Such an evil notoriety was attached to the name of Rugeley that the inhabitants petitioned the Home Secretary to allow the name to be changed. Lord Palmerston wisely laughed them out of their wish, saying, "If you want to change the name of your town, why not pay me the compliment of calling it after me?" The deputation retired, and the true significance of Palmerston's joke only dawned upon them on their way home.

Despite some repetitions and a certain looseness of construction, Dr. Fletcher's book is most readable and interesting. We only regret that it is not furnished with an index.

### NOTES ON BOOKS.

DR. FAIRBAIRN'S *Text-Book for Midwives*, which was first published in 1914, has recently appeared in a fourth edition, and it is therefore obvious that it is meeting with a well deserved popularity. In this new edition the main alterations are those necessitated by the recent revision of the rules of the Central Midwives Board and by the regulations regarding the lengthened training which will come into force a year hence. Similar alterations have been made in regard

<sup>2</sup> *A Practice of Gynaecology*. By Henry Jellytt, M.D., F.R.C.P.I. Fifth edition. London: J. and A. Churchill. 1925. (Roy. 8vo, pp. xiii + 744; 412 figures, 12 plates. 25s. net.)  
<sup>3</sup> *The Life and Career of William Palmer of Rugeley*. By George Fletcher, M.D. Cantab. London: T. Fisher Unwin, Ltd. 1924. (Crown 8vo, pp. 193; illustrated. 12s. 6d. net.)

<sup>4</sup> *A Text-Book for Midwives*. By John S. Fairbairn, M.A., B.M., B.Ch. Oxon., F.R.C.P. Lond., F.R.C.S. Eng. Fourth edition. Oxford Medical Publications. London and New York: H. Milford, Oxford University Press. 1925. (Roy. 8vo, pp. xiii + 365; 113 figures, 3 plates. 25s. net.)

to the rules of the Scottish Central Midwives Board where these differ from the English rules. Dr. Fairbairn has taken the opportunity of introducing some criticisms on points in which the regulations of the Scottish Board differ from those of the English. We are not sure that this book was quite the best place for such criticisms, which do not directly concern midwives or midwifery pupils. His observations are, we have no doubt, of the highest value, for Dr. Fairbairn is himself a member of the English Board, but they might, we think, have better appeared in the medical periodical press. This, however, does not affect the value of the book as a guide to midwives and midwifery pupils. It provides for them a thoroughly sound and interesting presentation of the whole subject, and can be heartily commended, especially to those who are studying for the examinations.

The importance of a child's mental and nervous health ranks equally with his physical health, and both are interdependent. *Safeguarding Children's Nerves*,<sup>5</sup> written by two doctors who have had considerable experience of the psychological problems of children, is published under the auspices of the American Child Health Association. The language is clear and not technical, and an endeavour is made to set out the elementary principles underlying the growth of the mental and nervous health of the normal infant and child. The avowed object of the book is to educate parents to protect the developing nervous system from both "the hardness and softness" of modern life. The book is pleasantly got up with a small picture at the head of each chapter, showing toddlers delightfully employed in the open air. The keynote of the book is to emphasize the importance of health and how to generate and maintain it. The authors say that most children will be normal in their nervous function if their parents and relatives allow them to be so: "Self-denial, self-control, and self-discipline, these are the all-important factors for the salvation of the nervous child from his own tendencies as he grows up." The book deals with heredity, rest and fatigue, discipline, habits, dreads, and dislikes. The treatment of defective and backward children is suggested. The concluding chapter gives a warning against charlatanry and advertised cures of various kinds.

The treatise of the fifteenth century physician, Giovanni di Albertis di Capodistria, on the plague, of which the full title is *De præservatione corporum a pestilentia et de causis pestilentiae et motis ejus*,<sup>6</sup> has recently been published by Professor ARTURO CASTIGLIONI of Trieste from the MSS. in the National Library at Vienna, together with a scholarly introduction which forms a valuable contribution to the history of epidemiology. The treatise is dedicated to the Emperor Frederick III, for whose personal use it appears to have been composed. It is divided into a series of chapters of very unequal length, in which, in addition to general observations on the cause of the disease and the time and places in which it occurs, a number of therapeutical rules are laid down, particularly as regards food, exercise, sleep, and drugs for local and internal administration.

The little book on *Small Pox and Vaccination*,<sup>7</sup> by Dr. BENJAMIN WHITE, Director of the Biologic Laboratories in the Massachusetts Department of Public Health; and a professor in the Harvard Medical School, is the latest addition to the series of "Harvard Health Talks," the aim of which is to supply the layman with information on medical subjects of general importance. An excellent account is given of the history of small-pox and vaccination, as well as of the prevalence of small-pox in those countries in which universal vaccination is not enforced.

The reference book entitled *The Medical Who's Who* (stated to have made its last appearance in 1918, though we have seen no later edition than that of 1915) has now been revived under fresh management. The new edition, bearing date 1925,<sup>8</sup> is more comprehensive than its predecessors, and differs from them in binding, in size of type and page, and in certain other respects, though the general plan has been preserved. While the volume is by no means a complete list of the medical profession at home and abroad, it is stated that "inclusion in this work is open to every registered

medical practitioner and that proper particulars are printed free of any condition, save only that of legal qualification." The entries appear in alphabetical order, and each name is followed by brief details of qualifications, professional work past and present, and date of registration, together with some particulars of a more personal nature. An index, arranged topographically, is appended, the London addresses being given in full. The type, though small, is very clear, and much care has evidently been taken in revising the material for the press. The rather flowery preface might be cut down with advantage in later editions.

The chief interest of Dr. LEO BUEGER's work on *The Circulatory Disturbances of the Extremities*<sup>9</sup> is that it contains a very full pathological and clinical description of thrombo-angitis obliterans, which is sometimes known as Buerger's disease. In addition to a detailed account of other diseases of the peripheral circulation, several chapters are devoted to anatomy and physiology as well as to capillary microscopy. The book, which is freely illustrated, will prove a valuable work of reference.

A revised edition of the *West London Hospital Pharmacopoeia*<sup>10</sup> has been published. Besides a considerable number of new formulae, dosage tables, notes on infant feeding, and the treatment of poisoning, charts of special diets have been included. Blank pages are provided for further additions, and the book retains its convenient size for the pocket.

<sup>5</sup> *The Circulatory Disturbances of the Extremities*. By Leo Buerger, M.A., M.D. Philadelphia and London: W. B. Saunders Company. 1924 (Roy. 8vo, pp. xiii + 633; 182 figures. 42s. net.)

<sup>10</sup> *West London Hospital Pharmacopoeia*. Revised edition. Leeds: L. Upcott Gill and Son, Ltd., The Avenue Press. 1925. (3½ x 5½, pp. xiv + 92.)

## MEDICAL AND SURGICAL APPLIANCES.

*A Drip for Continuous Intravenous Infusion.*  
Dr. H. H. MOLL (Resident Medical Officer, General Infirmary, Leeds) has devised a drip for the continuous intravenous infusion of glucose by the drop method. It is air-embolism proof and self-regulating. It consists of a small glass chamber and a rubber cork, in which two holes have been bored. One end of a piece of fine glass tubing is curved to the shape of a shepherd's crook; the other, connected by a rubber tubing to the main tank, is passed through one of the holes, while some rubber tubing is tightly fitted into the second hole and connects the drip to the recipient's vein. The drip is interposed between the main tank above and the recipient's arm beneath at any height, provided that the proximal loop of tubing, A, connecting the main tank with the drip, be at a lower level than the distal one, B, connecting the drip to the patient's vein. Water is then run through the drip for a few seconds. A negative pressure will develop inside the glass chamber of the drip, allowing it to be flooded up to a given level. By clipping the distal tube the rate of the drop can be regulated. Any obstruction occurring in the distal tube will cause the pressure within the glass chamber to rise so that the drip will stop flowing automatically. The drip can be disconnected from the main tank during the act of refilling without emptying itself, thus preventing air embolism. Mr. Charles F. Thackeray, Great George Street, Leeds, has undertaken to make the drip.

### An Anaesthetic Inhaler.

Dr. W. R. SOMERSET, honorary anaesthetist to the Wolverhampton and Staffordshire Hospital, has devised a new inhaler, which can be used for open or closed anaesthesia. The following advantages are claimed for it. It is simple in construction and economical in use, and with it nitrous oxide, ethyl chloride, a chloroform mixture, or ether, by the open or closed method, can be administered. The anaesthetic can be renewed by opening the lid and dropping it on to the pad without removing the inhaler from the patient's face. When used with closed anaesthesia very little vapour escapes into the atmosphere. In operations requiring a lateral position of the head it is possible for the anaesthetist to keep well away from the field of operation, and there is less interference with the work of the surgeon than when the ordinary mask is used. The metal face-piece is attached to a metal cylinder, which is divided by a vertical partition into two compartments, the smaller communicating at the bottom with the interior of the face-piece; while the larger compartment is closed at the bottom and opens at the top, with a projecting metal tube at the side. The upper end of the cylinder has a compartment with a pad of absorbent material to receive the anaesthetic, and there is a sump at the bottom of the large compartment to trap any excess of anaesthetic. Attached to the metal tube is a rubber bag with a tap at the extremity, to which an oxygen tube can be attached. Bayonet joints enable the cylinder to be turned so that the bag opens into either compartment as required.

<sup>5</sup> *Safeguarding Children's Nerves*. By James J. Walsh, M.D., Ph.D., Sc.D., and John A. Foote, M.D. With a foreword by Honorable Herbert Hoover. London: J. B. Lippincott Company. 1925. (Cr. 8vo, pp. ix + 272; illustrated. 3s. net.)

<sup>6</sup> *Libro della Pestilenza di Giovanni di Albertis da Capodistria*. Trieste: Lucio Capelli. 1924. (Roy. 8vo, pp. 67.)

<sup>7</sup> *Small Pox and Vaccination*. By Benjamin White, Ph.D. Harvard Health Talks, 13. Harvard University Press. 1925. (Fcap. 8vo, pp. 90.)

<sup>8</sup> *The Medical Who's Who*. Seventh edition. London: Grafton Publishing Co., Ltd. 1925. (Demy 8vo, pp. lviii + 770. 30s. net.)

## THE SIR WILLIAM OSLER MEMORIAL AT OXFORD.

## UNVEILING OF PLAQUE.

A BRONZE plaque in memory of Sir William Osler, Bt., F.R.S., M.D., F.R.C.P., late Regius Professor of Medicine, was accepted on behalf of the University of Oxford and unveiled by the Vice-Chancellor, Mr. Joseph Wells, M.A., Warden of Wadham, on the afternoon of Wednesday, June 10th, in the Court of the University Museum, in the presence of a large and distinguished gathering. Among those present were Lady Osler, Sir Humphry Rolleston, Bt., President of the Royal College of Physicians and Regius Professor of Physic in the University of Cambridge, Dr. J. G. Adams, Vice-Chancellor of the University of Liverpool, representing McGill University, Lieut.-General Sir William Leishman, Director-General Army Medical Service, the Dean of Christ Church, the Master of University (Sir Michael Sadler), the President of University, Professor E. B. Poulton, Professor Arthur Thomson, Professor Ramsay Wright, Mr. A. P. Dodds-Parker, and Dr. Ainley Walker (Dean of the Faculty of Medicine).

The plaque, which has been affixed in the University Museum by permission of the Delegates, is the work of M. Vernon of Paris, and is a replica of that made for the Faculty of Medicine of Maryland, U.S.A. It was presented to the University, on behalf of the subscribers to the Sir William Osler Memorial Fund, by the President of Magdalen, Sir HERBERT WANNER, who spoke in terms of warmth and feeling of Sir William Osler's services to Oxford and to Medicine, and of the charm and inspiration of his personality. He referred briefly to the remarkable growth and development of the School of Medicine and its scientific departments, since the time when Sir Henry Acland set to work to devote himself to the restoration of an almost derelict school. By their genius and enthusiasm he, and his successor, Sir John Burdon-Sanderson, infused new life into the school and launched it on the fresh career of usefulness to which the late Regius Professor so largely contributed.

The VICE-CHANCELLOR read a telegram from Sir Robert Hadfield conveying respectful admiration and homage to the memory of his late friend. The Vice-Chancellor said it was a very great personal pleasure and honour to him to accept the memorial on behalf of the University. There were many who knew Sir William Osler as a name of authority in medicine; but in Oxford he was remembered even more for his never-failing kindness, his sympathy, his love of children, and his magnetic personality. He was not only a great man, but a most lovable one. It was very fitting that his memorial should stand in a place connected with so many great men of Oxford, and especially of Christ Church, his own college.

After the Vice-Chancellor had unveiled the plaque a wreath of laurel and white heather was placed at its foot by Mr. J. F. Fulton, Magdalen and Harvard, on behalf of the Inter-State Post-Graduate Assembly of American Physicians and Surgeons.

## Tribute by Sir Humphry Rolleston.

SIR HUMPHRY ROLLESTON, in a brief tribute to Sir William Osler's life and work, said:

Osler's services to medicine, like the man himself, were remarkable for their infinite variety; his activities were not mainly confined, as have been those of some heroes of our profession, to one field, such as laboratory research, clinical observation, teaching, or education, for he played a prominent part in all these spheres. Osler first made his mark as a microscopist—in an investigation of the Canadian Diatomaceae, then of the blood-platelets, and somewhat later of the malarial parasite; and as a morbid anatomist at McGill, Montreal, he laid the firm foundations of that sense of proportion so essential for a physician. As a clinician he established new syndromes, such as erythraemia (Vaquez-Osler disease), hereditary telangiectases, splenic anaemia, and pointed out certain symptoms or signs in recognized diseases, so that "Osler's nodes" in subacute bacterial endocarditis are familiar. The most modern

methods of the laboratory were fully utilized to supplement the routine and thorough examination of the patient, the new and the old being skilfully blended so as to obtain the best of both. Like Trousseau he ranged widely over the whole field of medicine and enriched it both by observation and by deductions based on collected statistics—for example, in his studies on endocarditis, cancer of the stomach, and on typhoid fever; his literary output in forty-nine years amounted to more than 770 books, papers, and addresses.

Much learning is sometimes a handicap to a teacher, but ever young in mind, and with a wide sympathy and knowledge of young men—for he was their fellow student all his days—Osler was the ideal and inspiring guide of his pupils. He taught them, not medicine only, but humanity and the way of life, more by example than by solemn precept.

Ever active in the wards, his influence stimulated others to individual observation and research, and so to advance the science and art of healing. His writings, especially his great textbook, remarkable alike for its conciseness, completeness, and atmosphere of personal experience, brought him numberless followers whom he had never met. A happy manner of per-

suasive enthusiasm admirably fitted him as a great leader in campaigns for the prevention of diseases, such as enteric fever, malaria, tuberculosis, and venereal infection, and he not only originated but carried through successfully schemes, for the benefit of the nations. His most remarkable success, however, was as an educator of the medical profession; this was largely due to his personality and to the way he put into effect his motto, "Write me as one that loves his fellow men." A great believer in the educational and harmonizing influence of medical societies and in united effort, he was the moving spirit in starting the Association of Physicians of Great Britain and Ireland, and for its first twelve years the senior editor of its official organ, the *Quarterly Journal of Medicine*. These were but two examples of his many inventions for the good of his fellow practitioners. Devotion to old books and to medical history made him a power for a broad culture, and with Sir Norman Moore and his brother Regius of Cambridge he was largely responsible for the increasing study of this pleasant by-path in medicine. As a tribute to his wide sympathy with all forms of sound learning there could not have been a greater than his election as President of the Classical Association (1919), and thus he recalled the scholar-physicians, such as Linaere, whom he so much admired, and his profession was once more his debtor for an added prestige. We shall not look upon his like again.

The Regius Professor of Medicine, Sir ARCHIBALD GARROD, proposed a vote of thanks to the Vice-Chancellor for presiding, and referred to the position happily chosen for the memorial in close proximity to the statue of Sydenham, and near the figures of Harvey, Hunter, Acland, and Burdon-Sanderson. It had, he said, been the very good fortune of their medical school that the Regius chair had been held in succession by three great men. They recognized in Acland the parent of modern science in Oxford, of which that museum was the chief monument. They recognized in Burdon-Sanderson the father of their physiological department, which they knew to be unsurpassed, and fondly hoped unequalled, by any other university. It was only fitting that the third of these great men should be represented in that corner of the museum, which was in a sense a Valhalla of medicine. They of the medical school were proud of being members of a great university with no narrow outlook, but celebrated the world over as a seat of learning in classics, the humanities, science, law, and medicine.

#### THE OSLER MEMORIAL FUND.

By a recent Decree in Convocation the University of Oxford has gratefully accepted the Fund subscribed in memory of the late Regius Professor of Medicine, and has made the following regulations for its administration:

1. The fund shall be called "The Osler Memorial Fund."
2. A bronze medal shall be awarded once in every five years to the Oxford medical graduate who shall, in the opinion of the Board of Awarders hereinafter constituted, have made the most valuable contribution to the science, art, or literature of medicine, and who has not previously received the medal.
3. For the purposes of the preceding clause the term "Oxford

Medical Graduate" shall mean a person, whether man or woman, who has taken the degrees of bachelor of arts and bachelor of medicine at the University of Oxford.

4. The Board of Awarders shall be constituted as follows: the Vice-Chancellor; two professors of the Faculty of Medicine elected by the Board of the Faculty of Medicine; two persons not being members of the University, elected by the Hebdomadal Council on the recommendation of the Board of the Faculty of Medicine. The elected members of the Board of Awarders shall hold office for five years and be re-eligible.

5. All expenses in connexion with the award of the bronze medal shall be paid out of the income of the Fund.

6. The residue of the income of the Fund may be used at the discretion of the members of the Board of Awarders resident in Oxford in making grants from time to time to teachers in the Oxford Medical School, recognized as such by the Board of the Faculty of Medicine, to enable them to pursue some special study connected with medicine outside the University.

7. Applications for such grants shall be made to the Dean of the School of Medicine, who shall act as Secretary to the Board of Awarders.

#### First Quinquennial Award.

The bronze medal to be given every five years to the Oxford medical graduate who has in the opinion of the Board of Awarders made the most valuable contribution to the science, art, or literature of medicine has been awarded to Sir Archibald E. Garrod, K.C.M.G., F.R.S. D.M., F.R.C.P., Regius Professor of Medicine and Student of Christ Church.

The Board of Awarders consisted of the Vice-Chancellor Mr. Joseph Wells, M.A., Warden of Wadham, Sir Charles S. Sherrington, O.M., President of the Royal Society, Sir Humphry D. Rolleston, President of the Royal College of Physicians and Regius Professor of Physic in the University of Cambridge, and Lieut.-General Sir William B. Leishman, Director-General Army Medical Service.

## THE CHARCOT CENTENARY.

### COMMEMORATION AT THE ROYAL SOCIETY OF MEDICINE.

THE centenary of the birth of Jean Martin Charcot was commemorated by a conversazione and lecture at the Royal Society of Medicine on June 15th. The Fellows and guests were received by the President (Sir StClair Thomson) in the library, where, thanks to the assiduity of the honorary librarian (Mr. Walter G. Spencer), a very large collection of Charcot's writings, original and in translation, including his collected works in nine volumes, and his many essays in periodical literature, was displayed, together with the bibliography, at present only in manuscript, which Mr. Spencer has prepared. Various portraits of Charcot were also on view, including an oil painting lent by the Wellcome Historical Medical Museum, and a copy of the well known print of Charcot delivering at the Salpêtrière a clinical lecture to an audience which included most of the leading French neurologists of the time. Two specimens which Charcot himself brought over to the International Medical Congress in London in 1881, illustrating bone and joint lesions in tabes, were lent for the evening by St. Thomas's Hospital, to which he had afterwards presented them; one of them illustrated spontaneous fracture of the ulna, the other the condyles of the femur, showing the condition generally known in this country as Charcot's disease. The most recent of the Charcot memorials shown was the special medal which has been struck in Paris to commemorate the centenary.

Sir StClair Thomson mentioned that the gathering was honoured by the presence of M. Campana (French Consul-General) and some members of his staff, of Dr. Dubreuilh (Bordeaux), Dr. Jovan Popovic (Jugo-Slavia), a travelling Fellow of the Rockefeller Foundation, and of a number of medical officers of health from ten countries of Central and South America, who are at present in London, under the auspices of the League of Nations, for the study of public health administration. The Académie de Médecine of Paris, which had asked Sir D'Arcy Power to represent it on that occasion, had written cordially thanking the Royal Society of Medicine for joining in the commemoration of the great French physician. Professor Armand, the permanent secretary of that body, wrote that Charcot had

received no higher appreciation anywhere than among the profession in Great Britain. Nor was it forgotten in the Académie de Médecine that the great names of Ferrier and Horsley had secured for British neurology a conspicuous place in the medical science of the world, and that the Neurological Section of the Royal Society of Medicine was ably carrying forward the work of these illustrious seniors.

Dr. FARQUHAR BUZZARD, President of the Section of Neurology, then delivered an appreciation of Charcot. He began with an expression of gratitude to Mr. Walter Spencer for collecting the works of the great Frenchman and arranging them in the library. Those works were sufficient to show how numerous and versatile and historically important were Charcot's contributions to medical science. In a sketch of Charcot's life Dr. Buzzard recalled that he was the son of a working coach painter who, recognizing the brilliant abilities of his son, decided to give him a medical education. The turning point in Charcot's career was his appointment to be medical officer of the Salpêtrière, then what in this country would be called a Poor Law infirmary. He continued to occupy that position for thirty years, making it the chief neurological clinic in Europe. There, in 1866, he inaugurated his weekly clinical lectures, upon which his fame was largely built; in 1869 there appeared the first description of what was named in England Charcot's joint disease; in 1882 a professorship of neurology was created for him, and a neurological institute was founded in which his genius could exercise itself to the full. To get a proper orientation it had to be remembered that Charcot was about twenty years junior to Duchenne of Boulogne, who was the founder of French neurology. The two together might be said to have discovered a new field where the harvest was ripe for the gathering. According to a contemporary, Charcot was more of a co-ordinator and a man of method than a true inventive genius. But he was a pioneer of no ordinary qualities, and he lent distinction to every task to which he set his hand. He was second to none in his ability to make observations, and he excelled all others in his power of measuring the results of his labours and giving them their proper presentation, whether by pen or word of mouth. It

was difficult to think of an instance of a British physician who, in addition to making countless contributions to scientific knowledge, could compare with Charcot in his ability to attract students from all over the world by his inspired gift of exposition. Had he not been a physician, and had the stago been his career, he would not only have been a leading actor and stage manager, but no doubt he would also have painted the scenery and designed the dresses. Dr. Buzzard gave an interesting account of Charcot's domestic life and his daily routine, in which he was as methodical as in his scientific observation. He was not a proud man, he cared nothing for worldly distractions, and his artistic temperament—for he was no mean artist and connoisseur—left him curiously lacking in the ability to appreciate the value of money. He was generally so indifferent to the payment of fees that his patients would come to his secretary afterwards to be relieved of their embarrassment or would leave the fee surreptitiously behind them. The rank of his patients never impressed him. Once when a princess whom he kept waiting sent in some angry remonstrance, he remarked that evidently she was not aware that they had taken the Bastille! But he was, nevertheless, highly appreciative of the honorary distinctions which came to him in his later days from learned bodies all over the world. He was always ready also to give honour to others, and his appreciation of British medicine was high. He was the first to talk of Jacksonian epilepsy, he early recognized the work of Ferrier on cerebral localization, and he supported the election of Lister as a foreign associate of the French Academy. Charcot was to be regarded as one of the founders of neurology, a supreme exponent of the science and art of medicine, and probably the finest teacher of modern times. Dr. Buzzard concluded with some description of the recent centenary commemoration in Paris, which Sir StClair Thomson and himself attended. One of the events was honoured by the presence of the President of the Republic. Altogether it was perhaps the most wonderful tribute ever paid to any medical man, and it was paid to him, not as a scientist, nor

as a discoverer, but just as a physician whose work and personality had made a deep and permanent impression on the science and art to which he had devoted his talents and his life. It was difficult to imagine our own Government commemorating so enthusiastically the work of even a Lister or a Jenner.

Sir DAVID FERRIER, in proposing a vote of thanks, spoke of his personal acquaintance with Charcot, whom he first met, after some preliminary correspondence, about fifty years ago, when for a time he attended Charcot's clinic at the Salpêtrière. Charcot was then at the zenith of his fame. He had converted what was originally a large old workhouse infirmary into the most attractive and most visited clinic in Paris, or indeed in the world. There, in the out-patients' department and in the wards, he demonstrated the wonderful phenomena of hysteria, convulsions, and so forth, and in addition many forms of organic degeneration, such as disseminated sclerosis and the disease which bore his own name. The extraordinary power and fascination he had over his patients was very striking; he could get them to do anything. He was a man of dignified presence, rather sallow in complexion, his cast of face resembling that of the great Napoleon—a resemblance of which he liked to be reminded. On one occasion he had said to Charcot how much the lucidity of French writers was to be admired, and Charcot had answered that the French language did not allow anyone to be obscure. But Sir David Ferrier thought also that much was due to Charcot's own habit of clear thinking and his love of system. He spoke English well, though he was diffident about using it. One domestic recollection which Sir David Ferrier had was of Charcot's son, the distinguished explorer, Dr. Jean Charcot, then a boy of 6, reciting Gray's "Elegy." Shortly before his death Charcot promised to take part in the proceedings of the Neurological Society, but his death (in August, 1893) from angina pectoris occurred before the promise could be fulfilled. His reputation and achievements made him worthy to be called one of the glories of France.

## INTERNATIONAL CONGRESS OF RADIOLOGY.

LONDON, July 1st to 4th.

WHEN in 1891 Crookes discovered that certain corpuscular rays, known as the cathode rays, were created by an electric current passing through a high vacuum tube, there was no obvious indication that a new era in medical diagnosis and treatment was about to commence. Four years later, however, Roentgen discovered that if these cathode rays struck a solid body they gave rise to a hitherto unknown series of light vibrations—as he was not sure of their nature he called them *x* rays—which possessed great powers of penetration through many substances. The medical possibilities of this discovery soon became apparent, and its application became much simplified when Professor Jackson, in 1896, introduced an antienthodal target, thereby concentrating the area of production of the *x* rays and providing a focus for their origin. The gas tube in use to-day remains almost identical with Jackson's model. One of the first *x*-ray photographs taken was the achievement of Sir Oliver Lodge, and very early work was also done in this country by Campbell Swinton; a small plate by him showing the bones of the hand was the first *x*-ray photograph (skiagram) published in the *BRITISH MEDICAL JOURNAL*. The medical application of the new discovery was energetically investigated by Thurstan Holland of Liverpool, Mackenzie Davidson of London, and J. Macintyre of Glasgow, amongst others. Its use for the diagnosis of bone lesions was soon followed by its application to diseases of the kidney, the chest, and the abdomen. Gradually a specialty developed, and radiological departments were established in hospitals under the supervision of trained medical *x*-ray workers, now known as radiologists.

In 1897 the Röntgen Society was founded for the scientific study of the *x* rays, and the improvement of the apparatus by which they are produced; its first president

was the late Professor Sylvanus Thompson. A British Electro-Therapeutical Society was also formed for the investigation of the medical applications of the rays, and a few years later, when the Royal Society of Medicine formed an Electro-Therapeutical Section, the two were merged. At a much later date, in 1920, the British Association for the Advancement of Radiology and Physiotherapy was established, and owing to its representations the University of Cambridge established a diploma in radiology and electrotherapeutics. In 1923 a committee of these three societies, under the chairmanship of the late Sir Archibald Reid, resolved to found the British Institute of Radiology to serve as a clearing house for all matters pertaining to radiology in both its physical and medical aspects. The old chapel of the Russian Embassy at 32, Welbeck Street, was acquired and fitted up for its new purpose, as was described in our issue of November 8th, 1924 (p. 871).

Concurrently with this advance in Great Britain, similar movements were on foot in other countries, and attempts were made to arrange international meetings of radiologists. These plans were seriously interfered with by the war, but meetings of international scope had been held previously in Amsterdam, Germany, and elsewhere, and the British Medical Association encouraged this new department of practical medicine by arranging special sections at its Annual Meetings. Radiological journals also came into existence, and the *Acta Radiologica* of Scandinavia was prominent amongst those making an international appeal. The coming congress in London (from July 1st to 4th) represents, however, a new departure by reason of its magnitude and its extensive programme. It appears likely that a record number of delegates will attend, and that the number of countries represented will be unprecedented.

A matter of great importance has emerged in recent years—namely, the protection of radiologists. The British X-Ray and Radium Protection Committee, formed a few years ago by representatives of the three societies mentioned above under the chairmanship of Sir Humphry Rolleston, issued a preliminary report in 1921, and a second report in 1923; its recommendations have been adopted by almost every country in the world. The assistance of the National Physical Laboratory was invoked, and early in 1924 the committee issued the pamphlet mentioned in our issue of March 8th, 1924 (p. 434), defining various protective measures, both with regard to the equipment of radiological departments and the safeguarding of operators; it may be hoped that such tragedies as have occurred in the past will soon be entirely prevented. The co-operation of radiologists from all countries will materially aid in this by discussion and by the establishment of international standards.

#### INTERNATIONAL CONGRESS.

One of the first proposals of the British Institute of Radiology was to hold an International Congress in London in order to make its objects more widely known and to enlist the co-operation of radiologists in other countries. This proposal, which had the support of the Röntgen Society and the Royal Society of Medicine, met with a very favourable response, and, owing to the number of delegates who have signified their intention of being present (over a hundred representatives are expected from America) and the many papers which have been submitted, the work of the Congress is to be conducted in three sections. As the house of the British Institute of Radiology was not large enough for so many, and to accommodate also an exhibition of radiological apparatus, it has been found necessary to engage the Central Hall, Westminster, where most of the meetings of the Congress will be held.

The Congress will be officially opened on Wednesday, July 1st, at 2.30 p.m., by the Duke of Connaught, who will be accompanied by the Minister of Health (Mr. Neville Chamberlain). A reception will be held by the President of the Congress, Mr. Thurstan Holland, on the previous evening, at the house of the Royal Society of Medicine. As already said, the work of the Congress will be conducted in three sections: for physics, for electrotherapy and actinotherapy, and for radiology, respectively. On the morning of July 1st a joint discussion will be held by the Sections of Physics and Radiology on international units and standards for x-ray work. This important discussion will be opened by Professor Sir W. H. Bragg and Dr. Bédère of Paris. At the same time, in a separate session, papers of more strictly medical interest will be read, dealing with the gall bladder, with radium therapy, and with diagnosis of lesions of bones and teeth, with pregnancy and embryology, and with the urinary tract. On Wednesday afternoon, after the official opening, the discussion on international units will be resumed, and papers on the diagnosis of gall-bladder diseases and on radiotherapy will be read. In the evening the Sylvanus Thompson Memorial Lecture will be delivered by the Duc de Broglie of Paris, his subject being the absorption of x and gamma radiations and the secondary radiations which accompany them.

On Thursday morning the three Sections will continue their work, and among the discussions will be one on actinotherapy, to be opened by Sir Henry Gauvain. In the afternoon a visit will be paid to the National Physical Laboratory at Teddington by the Physics Section, and the other Sections will continue discussions opened in the morning. On Thursday evening, at 8.30, the Congress dinner will be held at the Great Central Hotel, Marylebone Station.

On the morning of Friday, July 3rd, Dr. Rollier and Dr. Leonard Hill will continue the discussion on actinotherapy, and papers will be read dealing with the thoracic organs and x-ray therapy, amongst other subjects. In the evening Sir Berkeley Moynihan will deliver the Mackenzie Davidson Memorial Lecture, on the relation of radiology and surgery.

On Saturday morning, July 4th, papers will be read on the use of radiology in the diagnosis of disorders of the nervous system and on x-ray therapy, and at 12.15 p.m.

the international delegates will meet to make arrangements for the formation of an international committee.

During the Congress an exhibition of radiographs will be on view in the lecture hall of the British Institute of Radiology, including many relating to papers read at the Congress. The Institute building will be used as a central bureau; visitors will be welcomed there, reception rooms being provided for members. A Ladies' Committee has been formed to make arrangements for entertaining the wives of members of the Congress.

An exhibition of radiological, electro-medical, and actino-therapeutical apparatus will be arranged at the Central Hall, Westminster, and will contain all the latest forms of apparatus from this and other countries, the American and German sections being well represented. In this exhibition will be included books and other objects of interest. Visits to Oxford, Manchester, Cambridge, Edinburgh, Glasgow, Salisbury, Stonehouse, and Winchester, with extensions, are being organized, and a garden party will be held on Saturday afternoon.

The President of the Congress is Mr. C. Thurstan Holland, Ch.M.; the Vice-Presidents are: Dr. A. E. Barclay, President of the Röntgen Society; Dr. Stanley Melville, President of the Electro-Therapeutic Section of the Royal Society of Medicine; and Sir Humphry Rolleston, President of the British Institute of Radiology. The general secretary is Dr. Stanley Melville, and the joint executive secretaries are Drs. J. E. A. Lynham and J. Muir, from whom copies of the programme and other information may be obtained. All communications should be addressed to them at the British Institute of Radiology, 32, Welbeck Street, W.1. The fee for membership of the Congress is two guineas. A detailed programme of the Congress has been prepared, and it is intended to publish the papers read at the Congress in the *British Journal of Radiology*.

#### ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee fifty-two cases were considered and £573 voted to thirty-nine applicants. The following is a summary of some of the new cases relieved.

M.R.O.S. (1913), aged 35, who helped his father in practice until the father's death last year. Applicant served in France, Salonica, and Egypt from 1914 to 1918, and was discharged on account of dysentery and malaria. Disablement pay £125 per annum. He discharged himself from hospital, but was taken suddenly ill, and is now in lodgings in London at a cost of £2 10s a week. An emergency grant of £20 to help with debts contracted during this illness was paid. The case was brought to the notice of the Fund by the Officers' Association.

Widow, aged 62, of M.R.C.S., who practised in London. She divorced her husband in 1906; he married again, and died in 1915. Since 1920 the applicant has supported herself as a housekeeper in several posts, but she suffers from severe varicose ulcers and has been obliged to give up her posts. She had cerebral haemorrhage on February 15th, 1925. Has recovered to the extent of getting about a little, but could only take a very light post. She has no children and no friends who can give any material assistance. The case was brought to notice by the Charity Organization Society. Voted £26 in twelve monthly instalments.

The daughter, aged 77, of M.R.C.S. Eng. who died in 1872. Applicant and her sister kept a girls' school until too old to carry it on. She has an annuity of £87 and earned £10 last year by teaching French and other languages. A boarder pays £1 a week. Friends contributed £20, and her rent and rates come to £77 per annum. Applicant's sister was an annuitant of the Fund until her death last year. Voted £12 in twelve monthly instalments.

Daughter, aged 29, of L.R.C.P. Edin. (1880) who died in 1915. Applicant was left with her brother and sister to educate. She has struggled to do this by letting and by clerical work. Her salary has been reduced to £2 a week, and letting brought in £32. Rent and rates come to £78 per annum. Applicant asks for help for the fees which are owing for her brother, who is in his last term at school, and for assistance to get him a post in a bank. His ambition is to be a doctor or architect to a solicitor. Her sister also requires some work. Voted £20 and referred to the Guild for further inquiries.

Wife of M.B. who has been in an asylum for the last four and a quarter years. The charges for him have been reduced to £58 a year, and his sister defrays half of this. The applicant's income is about £27 per annum. Her son, aged 26, is a junior clerk at £36 a year. Voted £16 in twelve monthly instalments.

Daughter, aged 69, of M.D. Edin. (1840) who died in 1881. The applicant, though deaf, has managed to support herself. Her only income is £60 from the "Dail" Fund, which she obtained in 1910. Voted £12 in twelve monthly instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., C.B., M.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

## GLANDULAR THERAPY.

THE discovery of the manner in which the ductless glands control the activities of the body is perhaps the most striking advance which physiology has made in the last half-century; but unfortunately the study of the physiology of these glands is beset with extraordinary difficulties, and every advance in scientific knowledge has been slowly and hardly won. Physicians, however, have been impatient of this halting progress and have made bold raids into the unknown far in advance of the consolidated positions, and the present result is that all sorts of therapeutic claims are being made which not only lack any support from controlled experiments, but in many cases actually are opposed to such facts as have been established.

The evils of this situation have been exaggerated by commercial interests, which have recognized a rich and easily exploited field. Every registered practitioner is, in consequence, deluged with literature giving lists of extracts of every organ of the body, and making sweeping therapeutic claims in respect of every one. Modern medicine is, indeed, threatened with a reversion to mediæval magic disguised under a pseudo-scientific terminology. Not long ago the *Journal of the American Medical Association* published a series of articles each containing short and simple summaries of what is really known regarding glandular therapy, thus providing the medical practitioner with a standard by which he can judge the truth of the commercial literature.

The articles, which were prepared under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association, have been reprinted in a small volume.<sup>1</sup> Three or four articles are devoted to each of the more important organs of internal secretion. There are twenty-two articles, all by different authors, and the list of contributors includes the names of many of the best known American authorities on the physiology of ductless glands and on glandular therapy. The articles set forth briefly such outstanding facts as have been established with reasonable certainty. The volume is of special value because at present the practice of glandular therapy is in rather an exceptional and doubtful position, for therapeutic practice has completely outrun established scientific fact.

The articles on the pancreas, thyroid, and suprarenal glands are excellent summaries of our present knowledge of these subjects, and as this knowledge is relatively advanced these articles contain fewer controversial statements than those in the second half of the volume, which deal with the pituitary, parathyroid, ovarian, and mammary glands. The writers on these latter subjects adopt an attitude of great caution. For example, Dr. Miller, who deals with pituitary gland therapy, is evidently doubtful whether extracts of the anterior lobe, when given by the mouth, have been proved to produce any certain therapeutic effects; and

Dr. McCann is even more sceptical regarding parathyroid preparations, for in concluding his article he expresses the opinion that "there is no single condition for which the use of parathyroid therapy rests on a firm foundation of scientific proof except the use of autotransplants in tetania parathyreopriva." Dr. Novak, in his article on ovarian therapy, is almost equally cautious, for his main conclusion is "that, rational as ovarian therapy appears to be in some conditions, the results are rarely striking and often nil to the level-headed observer. It cannot be assumed that a commercial extract can replace the normal ovarian secretion in the patient's body, or, for that matter, that it originally contains any of the active hormones of the ovary."

These quotations show that the articles are written in a spirit of healthy scepticism. Since the subject is contentious, most people will not agree with every conclusion, but the series as a whole represents very fairly the present attitude to glandular therapy of the majority of laboratory workers and critical clinicians. It will be found very useful by all those medical practitioners who are interested in glandular therapy, but who are not content to take commercial advertisements as their chief authority in therapeutics.

## SCARLET FEVER.

IN many different laboratories the new views on scarlet fever expounded by the Drs. Dick are being studied critically, and two medical men in Moscow have reported experiments on this subject conducted in Russia.<sup>1</sup> Their paper does not carry the question into any new territory, but it has an interest as a further confirmation of the Dick thesis. To some slight extent the Russian results differ from the American, but only in small matters of detail. Thus in Moscow the Dick reactions on healthy people gave a higher percentage of positive results than has been noted elsewhere. The Russian observers state also that persons who had formerly been ill with scarlet fever sometimes gave a positive Dick reaction on being retested.

Drs. George and Gladys Dick have published another article, entitled "Results with the skin test for susceptibility to scarlet fever: preventive immunization with scarlet fever toxin."<sup>2</sup> The first part of this paper contains a detailed account of the preparation and standardization of the toxin, both for skin tests and preventive immunization. The technical details here recorded should prove very useful to laboratory workers. There follow some observations on pseudo-reactions and different types of skin reactions, advice which will assist the interpretation of difficult or uncertain appearances. It is in the third section of this paper that the authors include the latest of their researches, concerned with active immunization by scarlet fever toxin. Here they have something fresh to say.

Scarlet fever toxin when injected subcutaneously is less injurious than diphtheria toxin, therefore it is not necessary to add antitoxin or to decrease the toxicity by chemical modification in order to employ it in amounts large enough to immunize. To ensure success preventive immunization with scarlet fever toxin must be carried to the point of a negative skin test, and the authors state that "if properly graduated doses are given at intervals of five to seven days, it is possible to immunize all susceptible persons to the point of a negative skin reaction without undesirable results."

<sup>1</sup> *Glandular Therapy*. A series of articles prepared under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association. Chicago: American Medical Association, 1925. (Small 8vo, p. 89; 3 illustrations.)

<sup>2</sup> *Journ. Amer. Med. Assoc.*, May 16th, 1925, p. 1476.

<sup>3</sup> *Ibid.*, p. 1477.

It seems that previous investigators have not given sufficiently large doses of toxin in preventive immunization. Thus, the New York City Health Department, which has employed scarlet fever toxin in preventive immunization on a large scale, has given doses too small completely to immunize the majority of susceptible individuals. Toxin, put up in inadequate doses, is also being widely distributed by commercial firms. Judging from the figures reported by the Dicks, the conclusion may be drawn that the average susceptible individual is not completely immunized until he has received a quantity of toxin equivalent to about 10,000 skin test doses of the phenolized toxin. The first dose should be about 500 skin test doses, the second of 1,500 skin test doses, after which larger quantities may be given without any undesirable reactions.

The active immunity produced by injections of graduated doses of scarlet fever toxin is acquired fairly quickly. Retests after immunizing doses of scarlet fever toxin, made at intervals of three days to a year in a series of 1,634 susceptible persons, showed that immunity commenced to show itself in one to two weeks. To determine how long the immunity lasts after adequate treatment with scarlet fever toxin, groups of persons with positive skin reactions were immunized to the point of completely negative reactions and retested at intervals of three months, six months, one year, and one and a half years. In each case the results were negative, proving that active immunity lasts at least a year and a half.

#### BRISTOL AND OXFORD.

WITH the Royal opening of the new buildings of Bristol University fresh in mind,<sup>1</sup> it is of interest to recall that in 1449 Gilbert Kymer, who had been rector of the Faculty of Physicians in London when the attempt to set up a conjoint college of physicians and surgeons (1423) failed, admitted, in his capacity as Chancellor of the University of Oxford, a certain John Free of Balliol College to the degree of B.A. Free became a Fellow of his college, and presently went to Bristol as rector of St. Michael's Church. But the revival of learning in Italy attracted him, so that with three or four friends he took passage in an Italian ship from Bristol, studied at the Universities of Ferrara, Florence, and Padua, and settled as a teacher of medicine in the first named. Leland credits John Free and his friends with being the advance guard of Englishmen who visited Italy at the renaissance of letters: "primus Anglorum erat, qui propulso barbarie, patriam honesto labore bonis literis restituit." His honest labour made little impression on the city from which he sailed, and higher learning met with small encouragement in Bristol, though schools have flourished down to present times whose pious founders were contemporary with John Free. University College, Bristol, was founded in 1877, and in 1909 King Edward VII granted a charter whereby the University College and the Merchant Venturers' Technical College were fused into a new university. There had been talk of this possibility for some years, but the men who ventured to imagine such an enterprise were regarded as foolish visionaries. Oxford, however, sent its new Regius Professor, Sir William Osler, in 1905 to support unexpectedly these visionaries. Osler, distributing the prizes to the students of the Faculty of Medicine, made the remark in his address that Bristol was the only medical school in Great Britain not in connexion with a university. The question was whether Bristol people had risen to the importance of founding a university with which this

medical school could be incorporated. There could be no question about the advantages to be derived from such a course, and he alluded to the remarkable growth of the medical schools in Manchester and other large centres. There were three essentials to the carrying out of such a scheme—capital, men, and buildings. When they had secured the capital they should not encroach too much upon it for buildings. They should then look for the men, for if the men were worth much it did not matter a great deal about the buildings. There were four kinds of university—first, those which had buildings but neither men nor money; second, those with men, but precious little money, and these often did the very best work; third, those with money and no men; and fourth, those like the one which they might establish in Bristol—a university with buildings, money, and men, which would be worthy of the Empire. Osler's address made a great impression, and his influence must be counted as a considerable factor in getting the university started. At the special congregation held at Bristol University last week, the Vice-Chancellor said that the University of Oxford, which had been closely associated with the university movement in Bristol, proposed to confer an honorary degree on Sir George Wills, joint donor of the magnificent new buildings; and a Latin address of congratulation and good wishes from the University of Oxford was read by Mr. W. W. Ward.

#### OCCUPATION THERAPY IN MENTAL DISORDER.

In his annual report for 1924 Dr. D. K. Henderson, the physician-superintendent of the Glasgow Royal Asylum, again draws attention to the fact that the number of voluntary admissions is approximately half the total admission rate. Naturally he regards this as a satisfactory condition of affairs, since it must mean that gradually the laity are beginning to have more confidence in mental hospitals. The public, he finds, are interesting themselves more in mental hospitals, and, irrespective of alarmist accounts, the distrust and suspicion which has been so prevalent is gradually being dissipated. This, he believes, is largely due to the fact that the relatives of patients, and the majority of patients themselves, realize that their treatment is kindly and considerate, and that everything possible is being done to promote recovery and betterment. Dr. Henderson points out that the institutional treatment of mental cases is by no means the largest part, and he considers that the problem of the care of the mentally ill should be viewed largely as a public health question, which can only be satisfactorily met by co-operation between the medical profession and the public. He refers to the fact that tuberculosis and other physical conditions have only been coped with by campaigns directed to the education of the people in regard to the causes of these diseases and in regard to personal hygiene, and he suggests that, though the problem of the mental health of the community is more difficult, it must be dealt with in the same way. Since a considerable proportion of the cases admitted into the hospital have shown mental symptoms for over a year, he regards it as essential that members of the medical profession should educate the public to seek earlier treatment and to assist in dissipating the idea that it is a family disgrace should one of its members be treated in a mental hospital. The existing overcrowding in mental hospitals Dr. Henderson thinks should be met, not by indefinite extension of the accommodation, but by attempting to devise better means for dealing with early cases and convalescents. He is of the opinion that mental hospitals have never sufficiently appreciated the importance of developing out-patient departments and of organizing social service and home care to a greater degree than has yet been attempted in this country. The account he gives of this work in connexion with the Western Infirmary is interesting, and

<sup>1</sup> BRITISH MEDICAL JOURNAL, June 13th, p. 1098.

indicates that much useful work is being done, especially by preventing mental illness from developing further, or sometimes by effecting a permanent betterment. The report draws attention, as in previous years, to the importance of the development of organized occupational therapeutic work. The Glasgow Royal Asylum now has two pavilions under skilled instructors, whose sole interest it is to occupy groups of patients. It is found that the value of this work is reflected in the general atmosphere of the hospital—the wards have been quieter and the patients better conducted. A series of papers by Dr. Henderson, Dr. A. G. W. Thomson, senior assistant physician of the hospital, Miss Brodie, lady superintendent, and Miss D. Robertson, instructress in the occupational department respectively, dealing with various aspects of this important work was published in the *Journal of Mental Science* last January. There can be no doubt that occupation therapy is one of the most important means of interesting the chronic patients in external affairs and in preventing them from sinking into regressive fantasies and general dilapidation. The ultimate aim of occupation therapy is not merely to interest the patients in modes of activity which are of no real value; it is to start them on work in the schoolroom, as it were, with the idea that they may in time gain a pleasure in useful work and become serviceable social units in the asylum community. In many cases, of course, to arouse interest in work is the first stimulus towards recovery.

#### THE NERVOUS FACTOR IN THE PRODUCTION OF CANCER.

ALTHOUGH it may be said that we know nothing certain at present of the cause of cancer, a considerable amount of knowledge has been accumulated regarding the conditions favouring its appearance in the body. Among these the influence of the nervous system has so far received comparatively little attention. In papers published in this *Journal* in 1903 and 1908, Lenthal Cheatle suggested that a definite relation existed between the incidence and spread of cancer and the innervation of the area involved, and he was able to adduce some striking clinical evidence in support of his theory. Cases recorded by him, in which an extensive rodent carcinoma was sharply restricted in its spread by an adjacent anaesthetic area of skin, are particularly striking in this connexion; and if the modern trend of opinion is correct, that the essential feature in cancer will be found to be a derangement of cellular metabolism, it is not improbable that the nervous system plays a part in the production of the disease. The subject has recently been taken up experimentally by Cramer.<sup>1</sup> His experiments, conducted in the laboratories of the Imperial Cancer Research Fund, London, deal exclusively with the production as distinguished from the spread of the disease, and it is clear that this distinction should constantly be borne in mind. The conclusion he deduces from his experiments is that, although cancer may arise in an area of skin which has been deprived of its nerve supply, the denervation does not induce a predisposition to the disease. This definite result does not, however, exhaust the problem of nervous influence, and Cramer points out that the chronic inflammatory irritation that so frequently constitutes a predisposing factor in the production of cancer is itself dependent on the integrity of the local nervous mechanism. Indirectly, therefore, nervous influence must be regarded as being of great importance in the production of cancer. The experiments referred to were made on mice. A piece of skin on the middle of the back, about 2 cm. long and 1½ cm. broad, was severed from the

surrounding skin and from the underlying tissues, and sewn on again with fine catgut so as to form an autoplast completely freed from nervous control. In some of the animals the severance was complete, in some the skin was left attached by a bridge of tissue 3 to 4 mm. broad. After complete healing the centre of the detached skin was painted with tar twice weekly, and, as a control, also the normal skin on the neck. At the end of nine months twelve of the surviving mice had developed tumours, and of these all had tumours on the normal area but only five on the operated area. Of the latter only one mouse developed a tumour on the operated area previous to showing one on the normal skin. Clearly, then, the operation had not induced any predisposition to the disease. In three of the cases the tumour appeared very late on the denervated skin (after more than seventy paintings), and it appeared probable, from the results of Meeks's observations on the regeneration of nerve plexuses, that nervous control had been re-established in these cases. If these three cases are excluded from consideration it appears that of nine mice, all of which developed tumours on the normal skin, only two showed growths on the autoplasts. An additional observation of interest was made with regard to the characters of the resulting tumours, those on the normal skin exhibiting a much more decidedly infiltrating character than those on the operated area.

#### SPIROCHAETOSIS RIVERENSIS.

New diseases in place of old always attract attention and excite critical consideration; syphilis and yaws have in the past been confused, and South America has several diseases of which we know little and have no experience. As the result of many years' work Dr. Louis A. Micheloni<sup>2</sup> of Montevideo, Uruguay, now describes for the first time a serious disease of spirochaetal origin which occurs in the department of Rivera (hence its name) and in the southern part of Rio Grande, Brazil. It is regarded as a transitional infection standing between syphilis and trypanosomiasis (gambiensis), and is a chronic meningitis which, while not proving immediately fatal, impairs health and leads to death by some intercurrent disease. Spontaneous cure, however, may occur in children and during adolescence, but is rare in adults. The spirochaete resembles *Spirochaeta refringens*, but is thicker and shows more active movement than the *Spirochaeta pallidum*, and is found in the cerebrospinal fluid but not in the blood. The Wassermann reaction is usually positive, but salvarsan and mercury fail to do good and may even do positive harm. It is usually conveyed along with gonorrhoea, and Dr. Micheloni believes that 75 per cent. of the whole population in Rio Grande are infected with the *Spirochaeta riverensis*. While gonorrhoeal pus does not contain the spirochaete, elongated nucleated cells, which may be a transient phase of the spirochaete, are found in it. The ocular symptoms are peculiar, and are thought to be pathognomonic; the spirochaetes are present in large numbers in the anterior chamber of the eye, and can be seen by the infected person; when looking at the sky, in a sort of dreamy way, the patient sees hundreds of thousands, possibly millions, of shining bodies moving quickly before his gaze. The two other cardinal symptoms are tinnitus and cardiac palpitation. The patients are extremely susceptible to ether and chloroform, and sudden death sometimes occurs after exertion; intercurrent infections, such as influenza, are likely to be severe. Dr. Micheloni suggests that patients infected with this spirochaete are thereby protected against carcinoma, but this appears to be no more than a surmise based on the rarity of malignant disease in the areas where spirochaetosis riverensis is prevalent.

## CENTENARY OF FARADAY'S DISCOVERY OF BENZENE.

THE centenary of the discovery of benzene by Faraday was celebrated at the Royal Institution, where he was professor, on Tuesday last, by the Royal Society, the Chemical Society, the Society of Chemical Industry, and the Association of British Chemical Manufacturers. Faraday himself seems to have attached little importance to the discovery, and turned away to the study of electricity, but his observations were the foundation of the synthetic chemical industry. In the morning a reception was held in the Institution, when a number of relics of Faraday were exhibited, and the President, the Duke of Northumberland, gave an address. He was followed by Professor H. E. Armstrong, and afterwards a number of British and foreign delegates spoke in praise of Faraday. Afterwards Lord Balfour made a speech, in the course of which he said that almost all, if not absolutely all, the most striking developments in the world of industrial production and scientific speculation were associated with the name of Faraday and intimately connected with his discoveries. In the world of practice and in the world of theory Faraday was one of the greatest builders the world had ever seen, but it would be a mistake to exaggerate the immediate effect of those discoveries. A generation had to pass before the first step was taken to turn the discovery of benzene into the commencement of the great dyo industry. Neither statesmen nor men of business had taken all they could from the actual knowledge science had already acquired. The new discoveries made daily in all countries could not be expected to produce an immediate result to be measured either in human convenience or in commercial dividends. In the evening a banquet was given in the hall of the Goldsmiths' Company, when the Duke of Northumberland presided over a representative gathering of British and foreign chemists. The toast of "Chemical science and industrial art" was given by Sir Alfred Mond and acknowledged by Sir James Irvine, Vice-Chancellor of St. Andrews University, Professor Norris, president of the American Chemical Society, and Dr. E. F. Armstrong, the newly appointed managing director of the British Dyestuffs Corporation, Ltd. Professor H. E. Armstrong, in proposing "Our court of assistants," said that one of the chief was benzene itself. The toast was acknowledged by M. Paul Kestner, Professor Cohen, Professor Katayama, Mr. Milno Watson, and Lord Blanesburgh. The Institution has founded a medal, to be awarded perhaps every six years, without regard to nationality, for an outstanding achievement in some clear relation to Faraday's discovery of benzene. The first award was made to Mr. James Morland of Carlisle and Grangemouth in recognition of the signal service he has rendered to chemical science and industry in this country during the last ten years by developing the manufacture of anthracene dyestuffs, and, more recently, by extending their application to silk and wool.

## PEMPHIGUS NEONATORUM.

OUTBREAKS of pemphigus neonatorum have recently occurred in connexion with maternity homes in this country, and to remind medical men of the chief features of this rare disease the Ministry of Health has issued a memorandum.<sup>1</sup> It is a highly contagious disease, and is characterized by the development of bullae or blebs which rupture and heal without a scar. They first appear as small pink spots resembling flea-bites; the spot enlarges, the overlying skin becomes pale and wrinkled, and fluid collects below until a blister half an inch to an inch in diameter has developed; when the covering layer bursts it exposes a round red moist surface surrounded by a bright pink border. Other

bullae may arise, coalesce, and when they burst leave an irregular raw surface. Pemphigus neonatorum is considered by many to be a variant of impetigo contagiosa, its special character being due to the peculiar nature of the infant's skin. Mild and grave varieties have been distinguished in different outbreaks. No severe illness accompanies the mild cases, which end uneventfully in a few weeks, whereas in grave cases extensive eruptions appear all over the body, attended by fever and signs of toxæmia. Such grave cases are often rapidly fatal from pulmonary oedema. Different types of germs have been accused of causing this disease, but no unanimity exists as to the exact nature of the infecting agent. But whatever type of microbe this may be, there is little doubt that the disease is spread by contact with infected material, and that the portal of entry is usually some slight lesion of the skin. Thus, the first bleb often appears at some point of pressure, or where two surfaces of the skin are in close apposition—for example, in the folds of the neck, axillae, groins, and flexures of the limbs. General infection may occur through the unhealed umbilicus, resulting in the early appearance of toxæmic symptoms. In the majority of outbreaks the attendant midwife is the original source of the infection and agent of its spread. Less often the mother or nurse has been discovered to be suffering from the common forms of impetigo or from whitlow. It is advised that the vesicles should be opened, drained, the edges exposed, and the base freely anointed with 2 per cent. ammoniated mercury ointment. Warm baths of weak potassium permanganate solution are said to be useful. The control and prevention of pemphigus neonatorum can only be successful when its highly infectious nature is understood. Nurses or midwives suspected of carrying the infection should be suspended from duty until they have been thoroughly examined and their equipment and apparel effectively disinfected. But the first requirement is early diagnosis of cases, which the Chief Medical Officer of the Ministry asks should be immediately reported to the local supervising authority, in order that prompt inquiry may be made to discover the person who is responsible, and the manner in which infection is being contracted.

## A RADIOLOGICAL METHOD OF INVESTIGATING HEART MOVEMENT.

At the meeting of the Röntgen Society on June 9th Dr. Robert Knox described certain work which has been proceeding in the radiological department of the Cancer Hospital on the investigation of the movements of the heart by the use of x rays with a slit diaphragm and a moving film. Attention was first drawn to this method of examination by Reider and Rosenthal of Munich in 1912, and by Crane in America in 1916; after this the subject seems to have been allowed to lapse for several years, until the opportunity came to Dr. Knox to investigate it further. The patient stands with his chest in front of the tube-box, which has a lead shield with a horizontal slit in the middle of it, and the film is placed in a moving cassette which travels slowly in a vertical direction past this slit so that upon the film there is exposed a continuous image of the moving edge of the heart. As a result of many experiments it has been found that the best records are obtained with eight seconds of total exposure, the film moving about sixteen inches during this time. The positions are so arranged that the edge of the slit to the left projects clear beyond the heart's shadow, or, if the horizontal slit is wide enough to cover the transverse chambers of the heart, the movements of both the left and the right edges may be presented. The resulting image on the film resembles in many points of detail the tracing obtained by the use of the electro-cardiograph. Practically all that the electro-cardiogram shows can be demonstrated by the x-ray record

<sup>1</sup> Ministry of Health, Memo. 103 Med. To be purchased directly from H.M. Stationery Office or through any bookseller. 1925. 1d. net.

the heart if a full examination is made of all its layers, and the x-ray record has advantages over the electro-cardiogram in that it is a faithful record of the actual movements of the pulsating heart. The film shows a number of outlines which are difficult to interpret; for a time it was not recognized that there were what might be described as primary and secondary lines. The primary, which are very pronounced, are obviously the records of the movements of the left ventricle and the right ventricle, the ventricular movements, if examined carefully, giving all the information afforded by the electro-cardiogram and the pulse tracing, and other information in addition. The secondary lines are more obvious on the left side, where the movement is greater. One wavy line appears at the point of maximum expansion of the heart in diastole, where the heart edge impinges upon the pericardium, pleura, and adjoining lung substance. Others on the right side are similarly caused by the transmitted impulses of heart movement upon a buttress of bone. By the use of this method it is possible to measure accurately the transverse diameter of the heart in any of the levels of the cardiac shadow, and to obtain information regarding the movements of the various chambers. In the case of the aorta the method has proved useful for estimating the size of the aneurysm transversely and the character of its pulsation, whether true or transmitted to other structures in its vicinity. It is believed that a comparison of the various measurements will be of the utmost importance in the investigation of cardiac diseases. The degree of dilatation can be estimated, and also the ability of the heart muscle to deal with the dilatation. The transverse width of the heart can be estimated readily by direct measurement from the tracing if the record of both edges of the heart is on the film, the width of the organ in systole and diastole is equally well ascertainable, and the difference between the two gives a rough estimate of the tone of the heart and its contractile power. It is intended to use the apparatus in the investigation of the movements of the normal aorta, to establish, if possible, the normal range of motion of its structure, and to apply the knowledge so gained to the pulsation in aneurysm of the aorta. Possibly the apparatus may also be used for the investigation of other forms of movement—diaphragm, stomach, oedema, and colon. One of the chief difficulties has been the inadequacy of the x-ray apparatus to give a record of the film through a thick subject because of the shortness of the exposure. This difficulty has been overcome to some extent by selecting thin patients, in whom it has been possible to get a faint record of the moving edge of the heart; but more powerful apparatus is required, and the possession of two or more times the intensity of the moderate power available would permit of the radiography of thick subjects at a distance of two metres. Work done at this distance, in Dr. Knox's opinion, would soon place the apparatus on a sound footing for clinical research.

#### EPIDEMIOLOGICAL BUREAU AT SINGAPORE.

In February the Far Eastern Epidemiological Bureau and Information Section of the League of Nations was opened at Singapore. A conference was held from February 4th to 13th, which was attended by delegates from twelve Far Eastern administrations. Arrangements were made for the operation of the bureau, the collection and transmission of epidemiological information to the Governments concerned and to Geneva, and for co-operation between the Governments concerned. The Government of French Indo-China has agreed to broadcast from the Saigon wireless station the epidemiological bulletins of the bureau once a week throughout the East, and to transmit them to Europe. Subject to final approval of the Governments concerned, the conference decided that the first appearance in any part

of Asia or Australia of cholera, plague, small-pox, yellow fever, or the unusual prevalence of any other infectious disease, should be reported to the bureau immediately; and that a weekly bulletin should be dispatched giving the mortality from plague, cholera, or small-pox, indicating the existence of plague infection among rats, and giving notes of any unusual epidemics. Weekly letters would also be forwarded giving supplementary information to the bureau, which would telegraph to all Far Eastern Governments and the head office at Geneva a weekly summary of all this information; monthly and annual publications would be issued later by the bureau. Any of the Governments concerned could obtain from the bureau at any time special information required. The weekly telegrams sent by the bureau will be cabled to Saigon and sent out by broadcast each Thursday, a special wireless message being sent to France and transmitted by telephone to the Central Epidemiological Service at Geneva. It was suggested that some form of advisory council should be established, including representatives of the countries concerned. The Rockefeller Foundation has offered a total sum of \$125,000 for five years on the understanding that if the bureau proves its value by the time this sum is exhausted, the Governments concerned will take the necessary steps to keep it in existence. The Singapore conference reported that it would be necessary to augment this contribution at no distant date. The representatives of Siam and the Straits Settlements stated that their Governments were willing to bear a reasonable share of the expenses of the bureau, and similar support was indicated from other countries. Dr. Gilbert Brooke, of the Straits Settlements Medical Service, has been appointed director of the bureau, and the first bulletin was broadcast on April 4th.

#### MEDICAL SCHOOL ORGANIZATION IN AMERICA.

Dr. A. L. Hoops, principal civil medical officer of the Straits Settlements, paid a three weeks' visit to the United States last year as the guest of the Rockefeller Foundation. He evidently made no holiday of his visit, unless change of occupation be regarded as a holiday, and even so, what he inquired into and learned related wholly to medical and public health questions. The outcome is a pamphlet in which he gives notes of what he observed in various places regarding various matters. These visits to American medical schools furnish information which could, no doubt, be extracted from official publications, but is conveniently condensed in his pamphlet. There are now about eighty such schools in the States, mostly connected with universities. The differences between the best and the worst of them are more marked than in the leading European countries, but Dr. Hoops points out that their degrees alone are insufficient to obtain a State licence for practice, a State examination being also required. He visited two of the best—Johns Hopkins and Harvard. A few schools require that a student shall have taken a degree in arts or science after four years at college before admission to the medical course. Others need only two years. These pre-matriculation studies are devoted to physics, chemistry, biology, and modern languages—French and German. A student is usually over 21 years of age when he applies for entrance to a medical school, and applicants are so numerous that the best schools have a wide choice. The minimum curriculum is four years, and some schools require five. Towards the end of the second year the elements of physical examination and diagnosis are taught in the outpatient department. The third and fourth years are wholly clinical, and after passing the M.D. (not M.B.) examination at the end of the fourth year, about three-fourths of the graduates obtain resident intern appointments in hospitals. At this time the State board examination is usually taken, and failure is the exception. The

intern residence is for twelve to twenty-four months, and the best of the men may stay on for two to five years longer, with free residence and perhaps a small salary, on condition that they devote themselves to intensive study in some special field of medicine. The American medical curriculum has recently been revised in the direction of shortening, the Harvard course being now 900 hours a year instead of 1,300. In preventive medicine and hygiene at Harvard great stress is laid on field work. Each student is required to make a sanitary survey of a city or town. The report consists of: (a) data; (b) interpretation of the facts; and (c) criticisms and recommendations. The survey includes history, geography, topography, climate, geology, population, health organization, water supply, sewage disposal, refuse removal, vital statistics, milk supply, nuisances, industrial hygiene, housing, infectious diseases, schools, markets, slaughterhouses, cold storage plant, educational pamphlets, diagnostic laboratory, meat inspection, district nursing, city planning, food and drug administration, etc. We do not observe any statement as to how long this survey, with its reports, usually lasts. Dr. Hoops also visited three hospitals—Johns Hopkins, Mount Sinai in New York, and a hospital in Boston. At the first named, disease prevention is taught in all the out-patient departments along with the curative work. Patients who can pay are charged anything up to 17.50 dollars a day, the cost being at least double this. The professorial staff are all whole-time officers, and their salaries are paid by the university, not by the hospital. Many other details are given in Dr. Hoops's interesting record of his visits. One conclusion is that in the matter of hustling he has not had much to learn from his hosts in his three weeks' tour.

#### MOSQUITO CONTROL.

In many localities in England and Wales happiness in summer weather, when we have any, is diminished by the mosquito. Even in the immediate neighbourhood of London there are pleasure haunts a visit to which is made memorable for the succeeding days by an almost uncontrollable impulse to scratch. The popularity of several delightfully situated seaside resorts also has been endangered by the mosquito or its congeners, until the local authorities have taken steps to abate the nuisance, unfortunately not always in the right direction, as was made clear in some notes on mosquito control communicated recently to the Portsmouth Literary and Philosophical Society by Mr. G. F. Marshall, Director of the Mosquito Control Laboratory, Hayling Island, Hants, who is known to some of our readers on account of the demonstration he gave to members of the British Medical Association during the Portsmouth meeting in 1923. We have in previous years published accounts of the progress of the campaign instituted on Hayling Island, and Mr. Marshall has now given a useful account of the various measures which may be taken in this country to control the mosquito pest. Mr. Marshall sums up the points for and against such different methods as surface oiling, the use of larvicides, and the abolition of mosquito breeding places by appropriate engineering methods. Naturally, no water should be treated with larvicide unless the presence of larvae has actually been observed, and in organizing a mosquito control campaign in any district the first step is to ascertain which species are prevalent in the neighbourhood, and then to estimate their relative importance as nuisance producers, so that those which are causing the greatest annoyance shall be the primary objects of attack. We notice that the Mosquito Control Laboratory at Hayling Island is offering a service, which will be of great value, by promising to examine and report free of charge upon all specimens of mosquito larvae and adult mosquitos forwarded by post.

#### "PROTOZOOLOGY."

UNTIL very recent times the animal parasites were not only much neglected both in the teaching of medicine and in medical literature, but periodicals devoted to their study were few. A little over two years ago we welcomed the appearance of the *Journal of Helminthology*, under the editorship of Professor R. T. Leiper, F.R.S., of the London School of Tropical Medicine, and director of the Institute of Agricultural Parasitology. We now have the pleasure of welcoming *Protozoology*, which is being issued under the same auspices. Hitherto no English journal has been exclusively devoted to this subject—a subject which includes the parasites of so many important diseases, including malaria, sleeping sickness, kala-azar, amoebic dysentery, and probably many others not yet fully understood. The Institute of Agricultural Parasitology has for its aim the solution of the many parasitic problems affecting animals and plants, and also, directly and indirectly, man. The new journal is intended primarily to provide a means of publication of original communications on the parasitic protozoa observed during the course of the work of the Institute. It is intended at present to issue *Protozoology* in separate numbers when required as a supplement to the *Journal of Helminthology*. The first number contains an article by Dr. J. G. Thomson on a *Giardia* found as a parasite of a parasitic nematode, and articles by Miss M. Triffitt on *Gastrocystis*—a common parasite of sheep in Britain—and on various *Coccidia* found in reptiles at the London Zoological Gardens. The illustrations are in line and half-tone. The new journal is a distinctly valuable contribution to the sciences of protozoology and parasitology, and we hope that the occasions for its appearance will frequently arise.

#### A TOWN-PLANNING JOURNAL.

SPECIALIZATION in modern activities leads to specialization in journalism, some of it ephemeral, some persistent. Of the latter type is the monthly magazine, *Garden Cities and Town Planning*, which is now half through its fifteenth year of publication; and is well written, well printed, and well illustrated. Its issue for June (a copy of which the secretary has sent us owing to the interest excited by the leading article on suburbanization published in our issue of May 30th) contains an article descriptive of no fewer than eight of the special constructive systems of house building which have been devised to meet the urgent national need for more and better dwellings at a time when the building industry is so short of labour that ordinary brick and stone houses cannot be supplied in anything like sufficient numbers. The way in which the brick and stone syndicalists are using their powers of obstruction is one of the most deplorable facts in the social life of the present day. That, however, is merely an aside, called forth by one of the articles in the magazine under notice. Other contributions include an exposition of the scheme of a Public Utility Society at the Garden City of Welwyn; reviews of recent books on housing; and an interesting lesson in mass production showing "How we get our doors." The journal is the organ of the Garden Cities and Town Planning Association, whose headquarters are at 3, Gray's Inn Place, W.C.1.

A DETAILED announcement appears on the first page of the SUPPLEMENT this week giving further particulars of the arrangements made by the Reception Committee, and confirmed by the Council at its last meeting, for the opening by H.M. the King, who will be accompanied by the Queen, of the British Medical Association's New House in Tavistock Square, on Monday, July 13th, at 3 p.m.; and for the dedication by the Archbishop of Canterbury of the Gates of Honour, erected in memory of members of the Association who fell in the war.

# NINETY-THIRD ANNUAL MEETING of the British Medical Association, BATH, 1925.

Doorway of St. John's Hospital. (From a wood engraving by Horace Gerrard.)

THE ninety-third Annual Meeting of the British Medical Association will be held at Bath at the close of next month, under the presidency of Dr. F. G. Thomson, physician to the Royal United Hospital, Bath, and consulting physician to the Royal Mineral Water Hospital. The Annual Representative Meeting, for transaction of medico-political business and discussion of the internal affairs of the Association, will open at Bath on Friday, July 17th. The statutory Annual General Meeting will be held on the afternoon of Tuesday, July 21st, and on the evening of the same day the new President will deliver his Address to the Association. The twelve Sections, among which the scientific and clinical work of the meeting is being divided this year, will meet on the three following days. The list of Sections and sectional officers, together with the full provisional programme and time-table and announcements about hotel accommodation, etc., were published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of June 13th, 1925. Further details of the arrangements will appear in later issues. On the last day of the meeting, Saturday, July 25th, there will be excursions to places

of interest in the neighbouring West Country. We publish below the third of a series of descriptive and historical articles on Bath.

## THE BATHS OF BATH.

BY

JOHN HATTON,

DIRECTOR OF THE HOT MINERAL BATHS.

THE Baths of Bath form what is probably the oldest curative establishment in the world. No less than eighteen and a half centuries have passed since the Romans founded their great *Thermae*, and from some time about the year A.D. 54, with scarcely an interruption, the hot springs of Bath have been used for the treatment of rheumatic diseases.

If, for a moment, we may leave the clear light of fact for the mists of legend, Bath's beginning as a place of healing is thrown back still another nine centuries, and the earliest patients are discovered to be a royal prince and a herd of swine. Taking into consideration the somewhat inadequate system of recording then in use, our earliest case record, remembering that its date is 863 B.C., is really remarkably complete.

Bladud, son of a British king, Lud Hudibras, becoming afflicted with leprosy, was banished from his father's court. Outcast, he secured the post of a swineherd in the Avon valley, only to transmit the disease to the swine. Dreading his employer's wrath, the prince drove the herd higher up the valley until they came to a hot swamp. Day after day the leprous pigs wallowed in the steaming morass, with the result that the disease entirely disappeared. The treatment having proved successful in the case of the swine, Bladud decided himself to try balneological measures, with equally happy results. Returning eventually to his home, cleansed of his leprosy, the outcast was welcomed and in due course succeeded to his father's throne. In later years he returned to the scene of his wonderful cure, there to found his capital, and, enclosing the springs, he built the first bathing establishment and

An interesting case, and a picturesque story, perhaps with more than a grain of truth in it; but the proximity of ancient ways and early settlements affords more reliable presumptive evidence of the pre-Roman use of the hot springs.

With the coming of the Romans we get on to surer ground, and in the wonderfully preserved remains of the Baths of *Aquae Sulis* the establishment of a definite system of balneology may clearly be seen.

Roman Bath was essentially a health resort. It was neither a military camp nor a city with a municipal charter, but a spa, drawing its patients chiefly from Britain—soldiers invalided from the garrison stationed in the island, a town councillor from Roman Gloucester—with an occasional visitor from the western parts of the Continent, from the places we now know as Trèves, Metz, and Chartres; no slight journey in those days, and an indication that the fame of the springs had become widely known.

### THE ROMAN BATHS.

The Roman Bathing Establishment, dating in its earlier portion from about the middle of the first century, appears to have been extended or altered at least twice during the subsequent three hundred and fifty years of Roman rule. Evidence of this is clearly seen in the eastern portion of the Roman Baths, which has been excavated during the last

FIG. 1.—Roman Circular Bath. (From a wood engraving by Horace Gerrard.)

two years. Here later hypocausts have been superimposed on previous Roman work, which in its turn had been built on a filled-in bath of still earlier date. When this middle-period work was broken through last year the still perfect masonry of the oldest bath of all was seen again for the first time since it was covered in by the Romans themselves, probably in the second century. At the moment of writing this newly discovered Roman work is not open to the public, but it will be on view before the British Medical Association meeting in July.

Occupying a hall 110 ft. by 68 ft., the Great Bath, with a water surface of 82 ft. by 40 ft., formed the principal feature of the Roman Bathing Establishment. The original pavements, or scholae, surrounding it are in a good state of preservation, and considerable portions remain of the rectangular and semicircular recesses or exedrae, similar to those at Pompeii, three on each of the longer sides, evidently provided for the clothes of the bathers or for rest and retirement.

The large bath was also supplied with a jet of cold water to serve the purpose of a douche or to quench the thirst of the bathers, a long section of Roman pipe remaining *in situ*, which appears to have been used for the purpose of conveying cold spring water to the bath.

Covering the floor of the bath is the original Roman lead, laid in sheets 10 ft. by 5 ft. and weighing 40 lb. to the square foot. The lead was obtained from the Roman mines in the Mendip Hills, a few miles from Bath, while the buildings themselves were constructed of Bath stone, obtained from the hills in the immediate neighbourhood. The preservation of the Roman carvings is a testimony to the lasting properties of this famous building stone.

The well known Roman system of bathing—the preliminary hot chambers, forerunner of the Turkish bath, followed by bathing in the large baths, with subsequent massage and the use of unguents—could here be carried out in every detail. All the baths were supplied with water from the hot springs, and from their construction the several bathing pools, of which no fewer than six have been discovered, appear to have been used at different temperatures.

A large circular bath, some smaller baths, and hypocausts or heating chambers, forming the system of hot-air baths, may also be seen, while, partly obscured by the foundations of the modern Queen's Baths, are other large baths indicating the vast extent of the Roman Bathing Establishment.

The recent excavations have resulted in discoveries of exceptional interest. Two large rectangular baths have been found, over which at later periods the Romans built hypocausts, the pilae of which still remain *in situ*. The apsidal ends of two sudatoria have also been found, one containing a portion of the original tessellated pavement supported on pilae, with the air-shaft intact whereby the heat was obtained from the furnace, which is still clearly visible.

The great culvert, built by the Romans for carrying off the waste water from the baths, has also been discovered, and, its masonry still sound and watertight, is now used for its original purpose, while under the King's Bath the waters of the King's Spring are still protected and enclosed by the Roman reservoir built in the first century to conserve the mineral water and prevent the admixture of any cold or surface water.

A small ante-chamber has just been built to enable visitors to see the head of the culvert and the Roman arch in the outer wall of the reservoir, and the steps which led to the dipping well whence the Romans drew the mineral water for drinking. Until this well was found it was always supposed that the Romans only used the waters externally, but the discovery of drinking cups in the bottom confirmed the view that from this

well, supplied, as is the Pump Room to-day, with water from the King's Spring, the Romans obtained the mineral water for internal use. An inscription over the bronze doors of the ante-chamber records that—

"This Hot Spring used by the Romans has been from time immemorial the principal source of the health-giving waters of Bath."

#### THE BATHING ESTABLISHMENT TO-DAY.

As this article is not intended to be a disquisition on Roman remains, it is time to leave the ancient and visit some of the modern departments of the bathing establishment. These represent a capital value of well over £200,000, and constant improvements to meet the advance of knowledge, and (so far as the past few years are concerned) almost continuous additions, have produced an exceptionally well equipped balneological institution.

Three buildings in close proximity form the principal part of the bathing establishment. The Queen's Baths, adjoining the Grand Pump Room; the Royal Baths opened in 1916 by Field-Marshal the Earl of Ypres on his return from France—a graceful recognition of the action of the Bath Corporation in placing the facilities of the baths at the disposal of the army medical authorities (and it may be recorded that Bath had the privilege of giving no fewer than 226,889 treatments to men wounded and invalided in the great war); and the Old Royal Baths, at present undergoing reconstruction as a suite for Plombières douches and large pool treatment. The Bath Street wing of the Royal Baths was opened in 1919 by Dr. Christopher Addison, the first Minister of Health, and the electrotherapy department was added a couple of years later.

Let us for a moment follow a patient visiting Bath for "the cure." First he will come to the booking office in the entrance hall of the Royal Baths, and there presenting his doctor's prescription, arrange the times of the treatments and receive the appointment cards and the bath tickets, purchasing at the same time a visitor's ticket, which gives the entrée to the Pump Room and the gardens and admission to the concerts and entertain-

ments—a kind of voluntary *kur-tax*.

Now he will go to one or other of the three main departments for his bath or other treatment. It may be a deep bath, the oldest and perhaps the most important form of treatment. Immersed in some five hundred gallons of the mineral water, freedom of movement is easy, and the under-current douche—a powerful jet of water usually at a higher temperature than the bath—can be applied to any part of the body. Patients too helpless even to walk down the steps are lowered into the water in chairs actuated by hydraulic power. Or he may be ordered the modified form of immersion in a reclining bath, or the more tonic procedure of the aeration bath.

When the stage is reached for something more vigorous perhaps some form of douche massage may be prescribed. Bath was the first spa to introduce the Aix douche into Britain many years ago, and the natural hot mineral water douche combined with massage and movements has ever since held a prominent place in the Bath system. There has been a great demand for both Aix and Vichy douche treatment; two of the Vichy douche suites are now being enlarged, and it is hoped, before the meeting of the

FIG. 2.—The King's Bath. (From a wood engraving by Horace Gerrard.)

British Medical Association, to have an entirely new suite completed and ready for use.

Intestinal douching on the Plombières system was introduced some years ago, and successful results necessitated more and more accommodation. Now it has been decided to concentrate this treatment in one building, and the visitors in July will find the Old Royal Baths in the process of being reconstructed into a suite of Plombières baths, embodying the details of equipment which have proved successful at Bath, together with the experience of Continental spas.

The Old Royal Baths were designed by John Wood the younger in 1778, and in adapting them to modern requirements every care has been taken to retain Wood's ingenious planning and the many delightful old features that give the characteristic Bath flavour. In the centre of the block is a large pool supplied direct from the Hot Bath Spring which will be used for the treatment of spastic and flaccid paralysis by voluntary and controlled movements, which has been in successful use at Bath for some time.

The concentration of the Plombières douches into the Old Royal Baths will release some particularly good rooms in the Royal Baths for vapour treatment, now given on the lower floor of the Queen's Baths. In certain gouty conditions, and in some of the subacute and chronic forms of eczema, this treatment by the vapour from the mineral water is much used.

Sir William Ramsay's estimation of the exceptionally high radium content of the natural gases which are given off from the springs led to the installation of throat and nasal sprays in which the mineral water is atomized by these radio-active gases, and of means whereby the natural gas may be administered by inhalation. The gas is 96.4 per cent. nitrogen and 3.6 per cent. CO<sub>2</sub>, and the nitrogen contains the rare gases argon, neon, and helium. The niton or radium emanation in the gas is equivalent to 33.65 milligrams of radium per million litres. The room for this treatment is in the Queen's Baths, directly overlooking the King's Spring, whence the water and gas are collected.

Many other methods are in use, but this article must not resolve itself into a mere list of treatments available at the baths; there will be many opportunities of seeing them all demonstrated during the third week of July. Brief mention, therefore, need only be made of the Department of Electrotherapy, where the usual light and heat treatments and the various hydro-electric methods are administered, and ionization, diathermy, high frequency, and other treatments are employed, usually in conjunction with the mineral water baths, which are often ordered only on alternate days. A useful addition—an ultra-violet ray room for general irradiation—was opened last month by Dr. Leonard Hill, F.R.S., director of the Physiological Department of the National Institute for Medical Research.<sup>1</sup> There is also one of the very few installations in this country of Zander machines for mechanotherapy.

There are two large swimming baths supplied with mineral water cooled to about 80° to 84° F., which afford an agreeable form of bathing for patients who have reached the convalescent stage and are ordered the full use of their limbs. And they fulfil the no less useful purpose of helping

to keep in health those who resort to them for the exercise of swimming.

#### *The Pump Room and King's Bath.*

The internal use of the waters is an important part of the "cure," and the Pump Room, where the waters are served for drinking, is the meeting-place of all who come to Bath. This handsome, well proportioned building, designed by Baldwin in 1796, bearing on the pediment the appropriate motto from Pindar, ΑΡΙΣΤΟΝ ΜΕΝ ΥΔΩΡ,<sup>2</sup> is a fine example of a great Georgian apartment. At one end is the musicians' gallery, and at the other a statue of Beau Nash by Hoare. Below is the famous Tompion clock to which Dickens alludes in the pages of *Pickwick*. It occupied a place in the first Pump Room, built in 1704 under the auspices of Nash, to whom the clock was given by its maker, Thomas Tompion, the most celebrated of all English horologists, in gratitude for benefits received from the Bath waters. Some of those, by the way, who motor from

London to the Annual Meeting—which they can do without getting stuck in the "bottle-neck" of Brentford now that His Majesty has opened the great wide way to the West—may remember that it was this same Thomas Tompion who was called in to measure with accuracy and precision the famous Bath Road, which he found to be 107 miles from London to Bath.

To return to the Pump Room where Tompion's clock still ticks—there are some beautiful original settees of Chippendale period and a couple of sedan chairs, and several portraits of notables connected with Bath.

The concerts proper—the morning music in the Pump Room is really to stimulate conversation and enliven the process of drinking water, actually odourless and almost tasteless, but declared by Sam Weller to have "a strong flavour of warm flat-irons"—are held in the concert hall of the Roman Promenade, a building designed by Brydon in 1897 and forming part of the same block. Here the Pump Room orchestra plays from October to May, while from May to October the band performances are given in one or other of the

parks and gardens. The Institution Gardens are quite near to the bathing establishment, and here during the summer season the waters are also served for drinking *en plein air*.

Perhaps the most interesting thing about the Pump Room is the view of the King's Bath from the large window on the south side. In the centre rises the King's Spring, the largest of the three hot springs supplying the baths and Pump Room. The others—the Cross Spring and the Hot Bath Spring—rise a short distance only away, within the precincts of the bathing establishment, the three yielding half a million gallons a day. The water rises at a temperature of 120° F., and in quantity and temperature the springs are entirely unaffected by climatic or seasonal changes.

In the eighteenth century the King's Bath was the fashionable bathing place, although when Pepys visited Bath in 1668 he "looked into the Baths, and found the

FIG. 3.—The Bath Street Colonnade of the Royal Baths. (From a wood engraving by Horace Gerrard.)

<sup>2</sup> ΑΡΙΣΤΟΝ ΜΕΝ ΥΔΩΡ—

"Which means 'The pure Element  
Is for Man's belly meant!'"

*Ingoldby Legends.*

<sup>1</sup> BRITISH MEDICAL JOURNAL, May 23rd, 1925, p. 582.

King's and Queen's full of a mixed sort of good and bad, and the Cross almost only for the gentry." The broad pencil of Rowlandson and other caricaturists found ample material in the mixed bathing of the Georgian period—the gentlemen in canvas waistcoats and drawers, the ladies' robes adorned with yellow ribbons. Floating on the water were little trays containing scents and sweetmeats for the delectation of the bathers, while their friends strolled on the broad paved promenade surrounding the bath, finding, with Christopher Anstey, that

"'Twas a glorious sight to behold the fair sex  
All wading with gentlemen up to their necks."

The handsome stone balustrade still exists, with the inscription recording that it was the gift in 1624 of Sir Francis Stonor, Kt., in return for relief given by the bath from "gout and aches in the limbs," the donor "living many years after well in health to the age of near ninety."

The brass rings in the walls, the votive gifts of grateful bathers between 1602 and 1784, bear many interesting

inscriptions. One is inscribed with the name of Barbara, Duchess of Cleveland, and another was presented by John Revet, brazier to King Charles the Second, who attributed his recovery to "God's Marey and Pumping."

Flowing from unknown depths for untold ages, the King's Spring is the very *fons et origo* both of the bathing establishment and the city of Bath itself. One side of the King's Bath forms part of the Roman *Thermae*, opposite is the wall of the eighteenth century Pump Room; the west end of the bath is the beginning of the present bathing establishment with all its modern equipment and scientific methods, while at the other end is the concert hall to remind us of the im-

portant part music and recreation now play in a spa cure.

To the building of the King's Bath Roman and Saxon, Norman and Tudor, Georgian and succeeding generations, have in turn contributed, thus, as an inscription on the south wall records, connecting in work and object the modern with the ancient world.

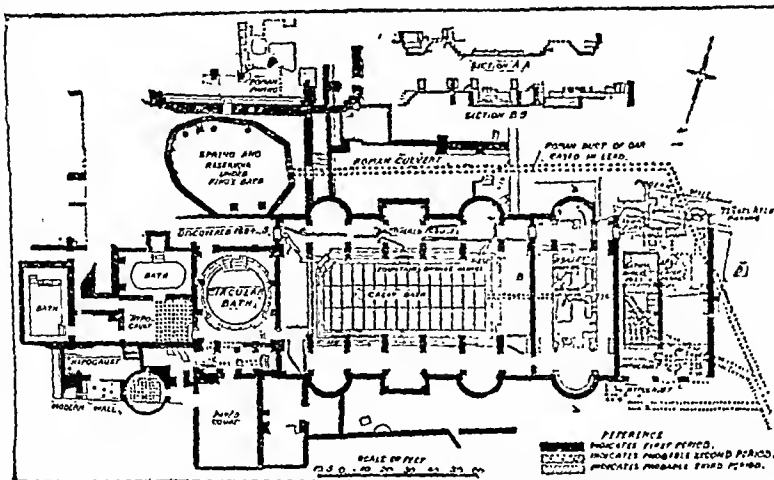

FIG. 4.—Plan of the Roman Baths at Bath. (By kind permission of Mr. Alfred J. Taylor, Architect to the Baths Committee.)

## England and Wales.

### NOTTINGHAM GENERAL HOSPITAL: RANSOM MEMORIAL LABORATORY.

THE new Pathological Laboratory of the Nottingham General Hospital, which has been instituted in memory of Dr. William Henry Ransom, F.R.S., and his son, Dr. William Bramwell Ransom, was opened on June 12th by Sir John Rose Bradford, K.C.M.G., C.B., F.R.S., consulting physician to University College Hospital, London. The ceremony was held in the board room of the hospital. Sir Charles Seely, who presided, read a message from Mr. James Forman, president of the hospital, expressing deep regret at being unable to be present and pay respect to the memory of two men, father and son, who did so much for Nottingham and its General Hospital. The chairman said that Dr. W. H. Ransom was appointed honorary physician to the institution in 1854, and continued as senior physician until 1890, when he resigned. His place was taken by his son, who carried on the duties until 1909. During their combined period of office the medical profession and the hospitals of the country performed one of the greatest services to the human race which any set of men had ever done; the happiness and comfort of life had increased enormously. In the general advance of medicine and surgery the Ransoms bore a full share of the work. He did not suppose anyone had striven harder for their fellow men, and with less regard for their own comfort and health.

Sir John Rose Bradford, in the course of his address, paid tribute to the distinguished services rendered by the Ransoms to medicine and to science, and to their work in promoting the welfare of the inhabitants of Nottingham. For over half a century father and son were identified with the manifold activities of the city. Neither confined himself to the narrow pursuit of his profession, but each took an active part in all work designed to make the individual more efficient for the discharge of his duties as a citizen. It was only fitting, therefore, that some acknowledgement in the form of a permanent memorial should mark the

appreciation felt by their fellow men for their devoted work. The elder and the younger Ransom resembled each other in that their early work was not concerned with the investigation of a definite medical problem, but was carried out with the object of elucidating some fundamental question in biology. In other words, before specializing in their life work as practitioners of medicine, they acquired a wide practical knowledge of the larger subject of biology, of which medicine was but a part. The history of medical science, like that of science in general, taught that the great advances had come about as a result of some discovery in what was misnamed abstract science. Nowadays the value of laboratories and laboratory methods in the daily work of medicine was so universally recognized that not only could no hospital dispense with one, but no practitioner could do his work without having means of access to such an institution. The Ransoms were pioneers in recognizing that development must take place, and each throughout his career developed such methods to the fullest possible extent under the conditions then existing. It was more especially for that reason that the form taken by the memorial was so singularly appropriate.

At the conclusion of the ceremony the Bishop of Southwell performed a short dedicatory service; and a vote of thanks was accorded to Sir Charles Seely, Sir John Rose Bradford, and the Bishop, on the proposal of the senior physician, Dr. F. H. Jacob, seconded by Mr. J. K. Wright. Afterwards the company proceeded to the new department in Amberley Street.

The Ransom Memorial Laboratory, designed by Messrs. Evans, Clark, and Woolf, is admirably equipped and is already in full working order. The medical staff has long felt the need of a pathological department as an integral part of the hospital. The laboratory is in charge of Dr. J. Kilian Clarke, late of St. Mary's Hospital, London.

### A NEW LONDON RESERVOIR.

Less than a generation ago it seemed not improbable that London would go to the mountains of Wales for its water. A Royal Commission made a long inquiry, and a scheme was drawn up, but to carry it out would have

involved a very large capital expenditure. Nothing came of it, and the Metropolitan Water Board proceeded to develop local sources. It seems now certain that water for London will in future, as at present, continue to be drawn from the Thames, supplemented by the Lea and certain chalk wells. Guided by its medical adviser, Sir A. C. Houston, Director of Water Examination, and by its engineers, the Metropolitan Water Board has succeeded in instituting effective methods of purifying river water, and the policy has necessitated the establishment of large reservoirs both for settling and for storage. Twelve years ago the King and Queen visited the then new reservoir formed at Chingford, in the Lea Valley; the ceremony took place at the tercentenary of the opening of the New River works due to the genius of Sir Hugh Myddelton. That reservoir, which bears the name of King George, has a capacity of nearly 3,000 million gallons, and cost £407,000. A still larger reservoir has recently been completed at Littleton, near Staines, for Thames water; its capacity is 6,750 million gallons, and when quite completed it will have cost £2,145,364, including all buildings, machinery, and conduits. Its banks have a circuit of four miles, embracing 800 acres, and when filled it could provide anchorage for a fleet of battleships. It is larger than all the other Thames Valley reservoirs put together, and will hold enough water to supply the seven million inhabitants of London for a month. The King, who was accompanied by the Queen, visited the reservoir on June 13th. After inspecting the intake from the river and then crossing a handsome granite bridge carrying the road over the intake Their Majesties went on to a granite platform forty feet above the bed of the reservoir; the King, by pressing a button, started the pumps and said, "I name this the Queen Mary reservoir." At a dinner in London in the evening, when Mr. J. C. Musgrave, chairman of the Metropolitan Water Board, was in the chair, the toast to the Ministry of Health was given by Mr. E. B. Barnard, who said that the undertaking of the Board was the greatest municipally owned thing in the world. Lord Long was right when he took the supply of water out of the hands of companies, because he believed that nothing touching public health should be subject to the temptation of profit. The toast was acknowledged by Sir Arthur Robinson, First Secretary of the Ministry of Health. Lieutenant-Colonel J. B. P. Karlake then submitted the toast of the constituent authorities, through whose co-operation it had been possible for the Water Board to carry out the work it had accomplished during the last twenty-three years in improving and supplementing the water supply of London. The toast was acknowledged by the chairman of the London County Council. Lord Desborough, chairman of the Thames Conservancy Board, in responding to the toast of "The Visitors," said that the Board's increased storage capacity would relieve the Thames Conservancy of considerable anxiety in times of drought. In 1921, when for some months the rainfall in the Thames Valley was little or nothing, instructions were issued to millers and lock-keepers to store water in the forty-seven reaches along the 136 miles of river. If the Water Board told the Conservancy that it wanted to pump water so stored it would be possible to save the metropolis from the menace of drought in future. Should London be menaced with drought this year, and the Board informed the Conservancy of its needs, the Conservancy could let down from the Cotswold Hills water thus stored and the Board could pump it up.

#### HARVEIAN SOCIETY OF LONDON.

The annual dinner of the Harveian Society of London was held on June 11th at the Connaught Rooms, under the presidency of Sir John Broadbent. A large number of distinguished guests were present. Sir Humphry Rolleston, proposing the toast of "The Harveian Society," referred to many present and past distinguished members, and also mentioned the Harveian Lectures. The President, replying, touched on various sides of Harvey's life and work, including the occasion of his appointment to St. Bartholomew's Hospital, when he drew up regulations for its internal administration. In these rules were instructions

that the surgeons should consult with the physicians in all difficult cases, and that the surgeons should not operate on the body nor give treatment without the consent and direction of physicians. All the regulations were approved by the hospital, but Sir John Broadbent believed that conditions had somewhat altered since. He referred also to Mr. Buckston Browne's gift of a portrait of Harvey and £1,000; the interest of this sum would be devoted to the presentation of a prize of £50 in alternate years, together with a medal designed by Mr. Langford Jones, who was present at the dinner. The toast of "The Visitors" was proposed by Mr. V. Zachary Cope, and Sir William Leishman, Sir StClair Thomson, and Sir Edward Marshall Hall replied. Sir StClair Thomson, speaking at times with something more than a shade of American accent, due, as he explained, to events of the last fortnight, referred to many of the visitors present in a characteristically witty speech. He repelled the insinuation that he himself was a visitor, and insisted that he had been a member of the Harveian Society for thirty-two years, and still paid his subscription.

#### THE MEDICAL WOMEN'S FEDERATION.

The membership of the Medical Women's Federation at the end of 1924 reached the figure of 900. At the annual meeting held last month in London it was decided that a fund should be raised for endowing a bed in the Taylor Memorial Home for Incurables, at Birmingham, in memory of the late Dr. Mary Sturge, a former president of the federation. Miss Frances Ivens was re-elected president at the half-yearly meeting of the council. Reports were also received from subcommittees appointed to consider lunacy reform, assaults on young persons, the defence of married medical women, and the Nursing Homes (Registration) Bill. The national corresponding secretary of the Medical Women's International Association stated that the association was extending in various countries; the German medical women had formed a national association with a membership approaching 600.

#### MEMORIAL TO THE LATE DR. T. D. LISTER.

On May 30th the council of the National Sanatorium Association entertained the delegates of the conference of the Post Office Sanatorium Society at the National Sanatorium, Benenden, and a memorial tablet to the late Dr. T. D. Lister was unveiled by the chairman of the Council, Mr. R. E. V. May. In an address the services of Dr. Lister to the Benenden Sanatorium and to the antituberculosis campaign in general were strongly emphasized. The tablet, which is in the entrance hall, bears the inscription: "Erected by the Council of the National Sanatorium Association, Benenden, Kent, to commemorate the untiring zeal and devoted service of Thomas David Lister, C.B.E., M.D., M.R.C.P., one of the founders of this institution, and for 17 years advisory physician to the Council, who by his personal sympathy endeared himself to all. Born January 30th, 1869, died July 30th, 1924." A tablet has also been placed in a room in the sanatorium to the memory of Dr. David Duncan Reid, who died last November. He was vice-chairman of the National Sanatorium Association, and member of the Hospital Saturday Fund Committee.

## Scotland.

#### PATHOLOGICAL BIOCHEMISTRY IN THE UNIVERSITY OF GLASGOW.

The University and the Royal and Western Infirmarys of Glasgow have recently received considerable benefactions for the purpose of promoting the advancement of medical knowledge by biochemical and other scientific methods. At each infirmary suitable laboratories are being provided and equipped, and the University has agreed to co-operate by providing at each a university lecturer in pathological chemistry, who shall also be appointed by the infirmary its clinical biochemist. The stipend of the joint post, which is a whole-time one, will be £700 a year. The duties include the giving of practical instruction in biochemical methods to students and practitioners, promoting the advancement

of medical knowledge by scientific investigation, and assisting the physicians and surgeons by undertaking chemical examinations and tests in relation to their patients. It is expected that appointments to the new offices will be made during the summer vacation.

#### MAINTENANCE OF VOLUNTARY HOSPITALS IN SCOTLAND.

In an address delivered to the annual meeting of the Scottish Clerks' Association in Glasgow, on May 30th, Sir George Beatson said that reorganization of the hospital system was urgently necessary. Suitable hospital treatment should be placed within reach of all classes of the community. What he would like to see in the hospital system was (1) improved co-ordination between all the hospitals; (2) abolition of Poor Law hospitals; (3) restriction of the services of the existing voluntary hospitals to the needs of poorer artisans and manual workers, with the adoption of a contributory system of payment carried out by insurance; (4) the establishment of paying hospitals with moderate charges for the upper middle classes; and (5) nursing homes with higher charges for the more wealthy classes. The question of approved societies providing hospital treatment for their own members was of great importance. This he thought might give a lead which would materially help to a solution of some difficulties in the hospital crisis. It seemed to him that there were three lines of policy open: one was to follow the present practice of making application to the voluntary hospitals in the usual way and waiting their turn of admission for free treatment while the society made a contribution to the funds of the hospital; secondly, an arrangement might be made with different hospitals for members who wished to be admitted as contributory patients making a payment based upon the cost of maintenance, and for this the society would require to charge its members a separate insurance fee; thirdly, the society might itself arrange to provide hospital treatment for its own members and dependants by having its own hospital, the cost to be met by a special insurance rate. He thought that no one could be satisfied with the system under which the voluntary hospitals were conducted at present, for they were largely utilized, free of cost, by patients for whom they were not intended. This state of affairs was not due to patients being unwilling to pay, but because hospital directors seemed unwilling to depart from the open-door plan, despite the fact that they saw it entailed financial embarrassment. To apply legacies to annual current expenses was open to grave objection and contrary to the first principles of sound economy. If hospital expenditure were examined it was found that it was divisible into two main groups, the first including the maintenance of the hospital itself (two-thirds of the annual expenditure), and the second the maintenance of the patients (one-third of the annual expenditure). He thought it would be a fair arrangement to place the larger amount on the general public and the smaller share on those who were less favoured financially. Such a maintenance payment need not be heavy and might be made up by a very moderate weekly insurance charge. He could only offer a very general calculation as to what the amount of this should be. Assuming, as hospital figures showed, that the stay of a patient in hospital averaged three weeks, the total cost for an operation case would be about £3 18s. 9d., for a non-operative surgical case £2 17s. 9d., for a medical case £2 6s. 9d. Such payments would relieve the hospitals of a great financial strain, would bring in an assured annual income, and would leave legacies and all annual subscriptions to be devoted to the upkeep and improvement of the hospital itself.

#### CLINICS FOR CRIPPLED CHILDREN.

At a meeting of the Edinburgh Branch of the Chartered Society of Massage and Medical Gymnastics held in Edinburgh for the purpose of raising the initial funds to establish a clinic where massage and remedial gymnastics would be available at a low cost for crippled children, Mr. W. A. Cochrane, F.R.C.S.E., indicated the close association between ordinary orthopaedic work carried out in hospitals and the work of the society in relation to all kinds of deforming and crippling diseases amongst children. It was important to link up such work with the care and cure of

the crippled child. There were in England and Wales at the present time about 150,000 crippled children, and these were being augmented at the rate of 15,000 a year. It was estimated by the Central Committee for the Care of Cripple Children that 10,000 beds were actually required for their treatment, while there were only 3,000 at the present time available under the county schemes in England. The waiting lists in hospitals were so large that the crippled child had to take his turn after more urgent cases, and was discharged immediately after an operation, so that after-care could not be carried on. Under the schemes for county clinics small clinics would be provided at different centres where after-care sisters, as they were called, could see the mothers and advise them. Cases would be drafted into hospitals as necessary and after treatment sent back to their homes to be followed up from the after-care clinics. This work was being done both in England and in Continental countries, while in America, as the result of a special organization, clinics were in operation all over the United States and Canada caring for about half a million cripples. How many crippled children there were in Scotland was not known, but he specially recommended this cause to public munificence and generosity.

#### HOME RELIEF FOR INCURABLES.

The annual general meeting of the Royal Society for Home Relief for Incurables, Edinburgh, was held in Dowell's Rooms, Edinburgh, on May 29th. Dr. William Robertson, medical officer of health for Edinburgh, presided. The chief object of the society is the payment of a money grant of the value of £10 a year to persons resident in Scotland who are certified to be suffering from incurable diseases, and who are, as a result, no longer able to earn a livelihood. The annual report stated that during the past year the sum of £4,784 had been paid in this manner. The chairman referred to the greatness of the work of the society, which lay in the fact that it threw gleams of light into the lives and homes of the most unfortunate. He was, however, glad to see on glancing down the list of diseases which called for their assistance that there were some which were preventable, and he would predict with considerable confidence that the demands on the society would be reduced when medical science was able to bring its weapons to bear on some of the diseases for which assistance was at present given.

#### NEW EDINBURGH HOSPICE.

The Elsie Inglis Memorial Maternity Hospital was visited on May 30th by the members of the Edinburgh Women Citizens' Association. The hospital, which will, it is expected, be open in July, will be staffed entirely by women. When in full working order there will be accommodation for 50 patients, in addition to provision for 10 ante-natal cases, 22 nurses, 8 resident women medical students, and the administrative staff. The building and grounds have cost £40,000, and this sum, together with sufficient money to pay for equipment, has already been subscribed. The income of the hospital will be derived from paying patients, from the maternity benefit of insured persons, and from public subscriptions. The number of beds used will depend largely upon the funds derived from the last-named source.

#### HOSPITAL COLLECTIONS.

At a meeting of the board of managers of the Royal Infirmary of Edinburgh on June 1st it was reported that the receipts during the past two weeks had amounted to over £7,050, including a sum of £5,161 on account of money collected by the pageant and other activities held on the badge day, Saturday, May 23rd. A contribution from the Prudential Approved Society in recognition of treatment received by members of that society for the quarter from March 31st, 1925, amounting to £709 15s., was also intimated. Last month an effort made by Aberdeen University students to raise funds for the local hospitals was completed, with the result that £4,945 was collected. An annual effort of a similar nature made by Aberdeen students during the past six years has resulted in the collection of a total of £22,039 for Aberdeen hospitals.

## CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, has just concluded. Out of 129 candidates, 120 passed. Of the successful candidates, 26 were trained at the Royal Maternity Hospital, Edinburgh, 24 at the Royal Maternity Hospital, Glasgow, 5 at the Maternity Hospital, Aberdeen, 13 at the Maternity Hospital, Dundee, 11 at the Queen Victoria Jubilee Institute, Edinburgh, 11 at the Cottage Nurses' Training Home, Govan, Glasgow, and the remainder at various recognized institutions.

INTER-STATE POST-GRADUATE ASSEMBLY  
OF AMERICA.

## VISIT TO LIVERPOOL.

A COMPREHENSIVE and varied programme had been arranged beforehand for the visitors on June 8th, 9th, and 10th. The staffs of the four general hospitals provided ample opportunity for the exhibition of cases, practical demonstrations, and varied surgical procedures. The formal welcome took place at the Liverpool Medical Institution on June 8th, where every facility was provided for the visitors to gratify their wishes in any department of medicine. The President, Mr. R. C. Dun, was in the chair, and in a short address assured his American colleagues of the pleasure the profession in Liverpool had in entertaining them. Several short papers were read on topics uppermost in medical literature at the present time. After tea an exhibition of cases illustrating children's diseases, orthopaedics, skin diseases, and nervous diseases took place. The exposition of these cases was much appreciated by the audience. Sir Robert Jones, who was present, often gave a practical demonstration either on his own arm or those of his interlocutor in connexion with the display of orthopaedic appliances. In the evening a musical soiree was held in the Walker Art Gallery, where the visitors had the opportunity of seeing the works of art and listening to an excellent programme of music.

On Tuesday the various hospitals were visited, and each department received a quota of Americans interested in its particular branch of medicine. In order to prevent undue crowding, tickets limiting numbers were issued at the Liverpool Medical Institution, which was thrown open to the visitors, and from which all information was supplied. The City Isolation Hospital and Sanatorium at Fazakerley claimed a large number, who took great interest in the methods of isolation in infectious disease and the treatment of tuberculosis by are light and surgical measures. At the Children's Hospital at Heswall clinical demonstrations of medical and surgical cases were given by the staff. The visitors admired greatly the hospital and the surroundings.

In the evening of June 9th the Lord Mayor held a reception, which was thronged with the medical profession from both sides of the Atlantic. On all sides expressions of appreciation from the visitors were voiced with animation and sincerity. The Town Hall was decorated with flowers arranged with great taste. Not a few of the Americans were accompanied by their wives, who were charmed with their surroundings, and regarded their visit to England as one to their old home. In the afternoon of June 10th a large party visited Ruthin Castle, North Wales, where they were entertained by Dr. E. I. Spriggs and the staff. Clinical demonstrations on recent work and methods were given and the institution thrown open to inspection. The historical interest of the castle added much to the pleasure of the visitors.

Mention should be made of Mr. Robert E. Kelly, on whose shoulders the chief burden fell in making the arrangements and so ensuring the success of this visit. The sincere expressions of pleasure from our American colleagues will have amply rewarded him for his labour in making their visit memorable in the annals of medical affairs in Liverpool.

## VISIT TO IRELAND.

The American doctors who travelled to Ireland divided themselves into two sections, each section visiting alternately Dublin and Belfast. During their visit in Ireland they were entertained at receptions and garden parties by the Governor-General of the Irish Free State, the Governor-General of Northern Ireland, the President and Executive of the Irish Free State, and the Lord Mayor of Belfast.

## DUBLIN.

The visitors attended nearly all the Dublin clinical hospitals, where they followed with keen interest the various surgical operations and demonstrations. A large number of the doctors also attended at University College (National University), where a discussion took place on the sequelae of encephalitis lethargica, opened by Dr. F. C. Purser. Sir James Craig presided.

The most noteworthy function of the day was, however, at the Royal College of Physicians, Kildare Street, Dublin, where a large gathering, representative alike of the visiting doctors and the members of the profession at home, assembled to witness the admission of Dr. Charles H. Mayo and Professor George W. Crile to the Honorary Fellowship of the Royal Academy of Medicine in Ireland. Professor Sir James Craig, M.D., T.D., President of the Royal Academy of Medicine in Ireland, presided, and on the platform were: Sir William Thompson, President of the Royal College of Physicians, and Mr. C. B. Mannsall, President of the Royal College of Surgeons, with their maces; Sir William de Courey Wheeler, Sir John Moore, Sir William Taylor, and Sir Thomas Myles. Dr. Charles H. Mayo occupied a seat on the chairman's right. Professor Crile was unavoidably absent.

The President of the Academy, Sir James Craig, extended a hearty welcome to the American doctors who had done them the honour of coming to Dublin. He hoped that they would return to their homes with nothing but the most sincere pleasurable memories of their visit; also with knowledge which had been gleaned at the source and from personal touch and experience. They were assembled, he said, to confer the Honorary Fellowship of the Royal Academy of Medicine in Ireland upon two very eminent American surgeons—Dr. Charles Mayo and Professor George Crile. The honour was small in comparison with the merits of the recipients, but this much might be said: that the honour was greatly enhanced because of the care exercised by the Council of the Academy in the selection of those only who occupied the highest position in scientific medicine. There were at the moment only twelve Honorary Fellows on their list, and only two had been conferred in the last thirteen years. He thought that the Academy had not been over-generous in its recognition of American work, but still there were found on the past roll the names of four Americans whose names were familiar to all. These were Thomas Addis Emmet, Austin Flint, Howard Kelly, and William Osler. They were now adding two to the number. Sir James Craig thanked Dr. Mayo, who is President of the American College of Surgeons, for the honour conferred on him in making him an Honorary Fellow of that body.

Introducing Dr. Mayo, the secretary of the Academy, Dr. T. P. C. Kirkpatrick, said:

"History tells us that the great Empire of Rome sprang from a city founded by two brothers, Romulus and Remus, and that city was afterwards saved from destruction by the prowess of the great twin brethren. In the empire of medicine we ourselves have witnessed the development of an institution which sheds its light and exerts its influence in regions Caesar never knew, yet which, like Rome of old, is the offspring of two brothers—the brothers Mayo."

In reply Dr. Mayo said that this was indeed a great honour. So many of his countrymen were there who had done remarkable work in their many lines in scientific medicine that he felt the honour extended to him was extended to them as he represented them. He was glad to see some members of that Academy wearing the robes of the College of Surgeons of America, of which college he had the honour of being President this year. He appreciated very much that they saw fit to wear these gowns

on that occasion. The science of medicine had been upheld in Ireland at a very high point—as high as in any place, considering the population and the number of men engaged in medical work. Irish medical men had contributed their portion to scientific advancement in many ways. Since he was a boy he had always thought of Dublin as a great centre of medicine. In his imagination he had expected to see the Rotunda Hospital something enormous. The enormous part of it was that it turned out literally hundreds and hundreds of men well trained in the special work carried on in the institution. The members of the Royal Academy of Medicine in Ireland were doing their part in a country that had never been wealthy, but whose people had always been great. The medical profession had always done its part, regardless of any political condition. Science knew no country and no language. He could not help thinking that one of the great things about the people in Ireland was their charity and their friendliness. They were always willing, regardless of whatever they had, rich or poor, to help those in need. They were appreciated in America and all the world over. He accepted the honour with a deep feeling of humility for his own shortcomings, but with a profound thankfulness that it would go back as representing the work of the many in America—the work of their two great associations, and in particular the work of the Mayo Clinic.

The Honorary Fellowship was conferred on Professor G. W. Crile *in absentia*. A number of the American doctors were entertained at dinner by Sir W. I. de Courcy Wheeler. During the proceedings the Governor-General (Mr. Healy), who was present, was admitted an honorary member of the Inter-State Post-Graduate Assembly of America. Dr. Charles Mayo said the Assembly had few honorary members and only three laymen as honorary members; these were President Coolidge, the Duke of York, and the Duke of Connaught; now they proposed to add the name of the Governor-General of the Irish Free State.

#### BELFAST.

On June 13th the Queen's University of Belfast conferred honorary degrees on three of the visitors. The ceremony took place in the examination hall of the University. The Chancellor of the University, the Marquess of Londonderry, K.G., presided, and conferred the degree of Doctor of Laws, *honoris causa*, on Dr. Charles H. Mayo, Dr. Franklin H. Martin, and Dr. H. Cabot.

In the evening the three new graduates were entertained to dinner in the Medical Institute by the medical faculty of the University and the members of the medical staffs of the teaching hospitals of the city. The Vice-Chancellor occupied the chair, and after the loyal toast of "The King" proposed that of "The Guests" in his usual felicitous manner; and his theme was supported by remarks from Professor Fullerton, Mr. Mitchell, and Dr. Dempsey. The toast was responded to by Dr. Mayo for himself and for Dr. Martin and Dr. Cabot, who were unavoidably absent. Dr. Woods Hutchinson and Dr. Peck were also called upon, and responded with thanks from the Assembly. Dr. Mayo then, as President, conferred the honorary membership of the Inter-State Post-Graduate Assembly of America upon Professor Andrew Fullerton, F.R.C.S.I., Honorary Fellow of the American College of Surgeons, and upon Dr. Robert Marshall, F.R.C.P.I., both of whom had been indefatigable in their efforts to make the visit of their American friends a success in every way. The announcement was received with loud applause, and gave great satisfaction and pleasure to all present, and will be gratefully recognized by the profession in Northern Ireland. The dinner ended with singing "Auld Lang Syne" and the National Anthem.

Owing to a clerical error in the list officially supplied to us of those representatives of British medicine upon whom the honorary membership of the Inter-State Post-Graduate Assembly of America was conferred during the London visit, we omitted to state last week that Sir James Berry, F.R.C.S., was one of those to whom this honour was paid.

## Correspondence.

### MEDICAL EDUCATION IN WALES.

SIR,—I have been much interested in the article on the Welsh Medical School question in your issue of June 13th (p. 1094); but I trust you will allow me to say that the writer does not seem to me to be quite fully informed as to the facts of the case.

The policy of separating the Cardiff School of Medicine from its parent college was not a recommendation of the recent Royal Commission, but a demand of the Treasury, made before the Commission was appointed, with reference to an application from the college for the State endowment of the school, and as a condition of considering it. The Treasury in those days had ample reason to apprehend that the award of such a grant to a single college of the university would be speedily followed by commensurate claims from one or both of the two others. The college at Cardiff was at first disposed, in the interests of the school, to enter into some such arrangement with the Treasury, and the Royal Commission recommended what they held to be the best method of carrying it out; but after the issue of their report a good deal of public opposition to the idea of separation manifested itself, a change was about the same time introduced in the mode of assessing State grants to the university and its colleges, the Government dropped the subject, and the new Charter of the University of Wales, based on the Commission's report and granted by the Crown in 1921, made no reference to it, but specifically indicated "the University College of South Wales and Monmouthshire" as the seat of medical education in the university (cf. Art. XVII, 2, and Art. VI, 2, viii and ix). The present aim of the Privy Council, seemingly, is to wave aside Crown, Government, and Commission alike, and to force the university and the college into accepting a new scheme of separation, stated to have been drawn up by the University Council, apparently at the instance of Whitehall.

This new scheme, instead of erecting the medical school into an independent constituent college, as the Commissioners advised, proposes to relegate it to an institution of inferior rank and lesser privilege, under the name of a "school of the university." The article I am referring to seems to suggest that this scheme has the approval of the faculty of medicine of the university; my information is that it has not yet been before the faculty.

That the scheme is wholly illegal under the existing charter of the university is plain to anyone who knows that document; the curious point is that none of the promoters of the scheme, either in Wales or in Whitehall, appear to have discovered this fact until the college pointed it out.

What public advantages are anticipated from the proposal the college has yet to learn. No statement on the subject has so far reached it. It is a subject, indeed, on which the advocates of separation have always shown themselves singularly reticent. The obvious and grave objections, financial and academical, to the proposed isolation of the medical school were forcibly pointed out some months back by a very competent authority, the present Vice-Chancellor of Liverpool, in a communication to the *Western Mail*. They have, further, been set out at length in the reply that the college has just made to the Privy Council, which also has been communicated to the press. The college, at least, has no occasion for secrecy in the matter. As regards the "nationalism" of the school of medicine, all the University Colleges of Wales, in their entirety, are national institutions, and, like the medical school, receive a large part of their income from a national fund, to which all parts of Wales contribute.—I am, etc.,

Weston-super-Mare, June 15th.

ISAAC OWEN.

### PERINEAL DRAINAGE AND PROSTATECTOMY.

SIR,—For many years I have invariably employed perineal drainage after internal urethrotomy. At the completion of the operation the urethra is opened by a small incision in the perineum and a rubber tube introduced into the bladder. The tube, which has a lumen about equal to that

of a No. 12 catheter, is sufficiently long to drain comfortably into a urinal between the patient's legs or on the outside of the thigh. It is kept in position by a silkworm gut suture, which fixes it to the skin of the perineum. The tube is well tolerated, and is left in for five or six days. No instruments are passed along the urethra for twelve days, after which a No. 12 bougie is passed daily. The perineal wound quickly heals, and the patient almost always is fit to leave the hospital in sixteen days. There is no reaction when perineal drainage is employed in this way, and the absence of fever and discomfort is in marked contrast with my earlier experience when a catheter was tied in the urethra.

I was led to employ perineal drainage after prostatectomy in the case of a highly nervous man who was suffering from cystitis of several months' duration.

The cystitis was set up by the passage of a catheter for retention of urine. He was very intolerant of catheterization and so excitable and unmanageable that a two-stage operation would have been difficult to carry out unless a general anaesthetic had been given each time. The bladder was opened under a general anaesthetic and the prostate removed. A tube was then introduced from the perineum into the prostatic pouch—its exact position was easily ascertained by a finger introduced into the bladder from the suprapubic wound. The prostatic cavity was then packed with gauze in the usual way. After forty-eight hours the gauze was removed and the bladder washed out through the perineal tube. Urine flowed freely through the tube and was collected in a bottle. Twice a day the bladder was irrigated with weak silver nitrate solution and the perineal tube was left *in situ* for a fortnight. The patient made a perfectly smooth recovery and the suprapubic wound healed in about three weeks.

Since then I have employed perineal drainage on several occasions, and with uniformly satisfactory results. The introduction of the tube is very easy: the urethra is opened by cutting down on to a Wheelhouse's staff in the urethra; the tube is then guided into the prostatic pouch in a curved pair of forceps and fixed in position by a silkworm gut suture, which transfixes it and the skin in the perineum. The advantages are that: (1) irrigation of the bladder and prostatic pouch can be carried out easily and efficiently; (2) urine escapes from the bottom of the bladder and the pool of pus and old clot which tends to collect in the prostatic pouch is prevented; (3) the patient is comparatively dry from the first, very little urine escaping from the suprapubic wound after the removal of the gauze; (4) convalescence is shortened, the suprapubic wound healing in a time appreciably shorter than usual.

For the reasons given, the greater comfort secured to the patient, and economy in dressings, I consider that perineal drainage confers real advantages. Although my experience of it is as yet too limited to enable me to dogmatize, I believe that it will materially diminish the risk of late septic troubles which develop when the suprapubic wound is closing and of phosphatic deposits in and upon the walls of the prostatic pouch.—I am, etc.,

Edgbaston, Birmingham, June 11th.

WILLIAM BILLINGTON.

#### SUBURBANIZATION.

SIR,—The thanks of your readers are due to you for the excellent leader in your issue of May 30th on suburbanization. We cannot afford to make any more mistakes such as those which created our slums. We have no longer vast profits to spend as we like, for we have not the monopoly of manufacture, nor are we now the workshop of the world. The mistakes of to-day will be even more serious than those made a century ago, unless we can regain our lost markets. But there is another reason why we should scrutinize new buildings. In the past a house may have had its own well and its own cesspool, its oil lamps or candles, and a lightly made road to serve the light traffic. Now the road must bear heavy motors on six inches of concrete, beneath which run sewers, gas, water mains, and lighting cables, not to mention power cables also where such are in use. All this is costly beyond the dreams of our ancestors. It must be done, but the road and the services beneath it should be laid out to the best possible advantage—that is, the road should serve as many houses as possible, and therefore should be as short as possible. A ribbon of houses fringing a long arterial road must need more roadway, more sewerage, more gas and water pipes and electric cable than the same number of houses well

laid out round a central point, from which roads and services would radiate, and to which the citizens would come for common purposes, not only for amusement and education, but also for local self-government. Such a centre should be an ornament and an attraction to the town, like some of the squares in Florence or Venice.

What our forefathers did in walled towns surely we could do when we are no longer pent in behind fortifications. Towns need not be ugly, and with modern improvements traffic need not be either dusty or noisy. It is hard to believe that if once we made our towns graceful the people would fail to take a pride in them. Then perhaps the streets would not be littered with bus and tram tickets, mixed with greasy papers thrown down by the customers of the local fried-fish shops. I fear to trespass further on your space, but I hope that the medical profession may be roused to do all that is possible to prevent any further suburbanization on ribbon lines.—I am, etc.,

June 11th.

SENEX.

#### DOCTORS AND CORONERS' (? INQUEST) FEES.

SIR,—Until comparatively recently, should a coroner require medical evidence of the cause, or probable cause, of a death, the usual method of procedure was for some medical practitioner to be instructed, through the medium of the coroner's officer, to make, or cause to be made, a *post-mortem* examination, with or without an analysis of the contents of the stomach, and to present himself before the coroner's court on some future date, then and there to give evidence touching the death of A. B. and therein fail not at his peril.

For the carrying out of these instructions he was legally entitled to the princely fee of two guineas in all—namely, one guinea for performing the revolting work of the *post-mortem* examination, and the other guinea for his medical evidence at the subsequent inquest.

Out of the first guinea he could not do otherwise than "tip" either the mortuary attendant, who assisted at the *post-mortem* examination, if there was a mortuary, or the assisting policeman, if there was not a mortuary, or both these men. So far so—bad, as regards the adequacy of the fees.

Legally, moreover, the doctor could, though he hardly ever did, refuse to give his evidence in the coroner's court until he had received his fees, such as they were.

Recently, in country districts, it has frequently been the coroner's method, where a "certificate of the cause of death" is refused by a doctor, to send the coroner's officer, or the nearest resident policeman, to "pump" the doctor as to his opinion as to the cause of death, with a request that he (the doctor) should provide "a provisional death certificate," or such information as may enable the coroner to grant a death certificate himself without any inquest being held at all. For doing this the doctor is informed that he will receive "the usual fee," and, after a considerable interval, for complying with this ingenious demand, he receives a visit from a constable, who tenders him the fee of—three shillings and sixpence! for which he must sign a formal receipt. This corresponds to an ordinary day attendance police-call fee.

Once or twice I have been instructed to visit and view the corpse and report, to the best of my ability, without, of course, any *post-mortem* examination or inquest being held at all. In both instances the fee tendered was the same—three shillings and sixpence!

In this locality there are a very large number of the sect of "the Peculiar People," whose monomania is, roughly, a disbelief in any medical or surgical treatment, and the absolute refusal of either. Should death appear probable to the "elders" of this sect, or to the friends of the patient, and only then, a doctor is called in, in the hope that a death certificate may be obtained, the doctor being thus placed in a position enabling him to state when he last saw the patient alive, and so obviate the necessity for "opening the body," etc. Of course, all treatment is refused, even though in the doctor's opinion life might have been either saved or prolonged. Such certificates, I need hardly say, I invariably refuse to give.

Now, Sir, I ask for enlightenment on the following points:

1. Is a doctor obliged, on the coroner's instructions—written, verbal, or telephoned—to act as above stated, and that for a three-and-sixpenny fee (irrespective of mileage)?

2. May he refuse to render to the coroner any opinion he may have formed as to the cause of a death, until he has received (or been guaranteed) the recognized inquest fee of one guinea, which of course he could have demanded had an inquest been held?

3. Is a doctor legally obliged to perform a *post-mortem* examination on a coroner's order, or, failing this, cause such an examination to be made by somebody else?

Only a few days ago the village constable called upon me and tendered to me ten shillings and sixpence as representing three fees for obliging the coroner, as above stated, on three separate occasions, all of which happened some considerable time ago, and for which I had to sign the usual formal receipt.—I am, etc.,

June 15th.

WILDMAN E. BAKER.

#### DISEASES DUE TO FASHION IN CLOTHING.

SIR,—I can confirm the cause of erythema of the legs in young women suggested by Dr. Gibson (June 6th, p. 1059). A young relation of my own told me she had something the matter with her legs, and I found she had erythema, with slight irregular swelling of both legs from knee to ankle. Later I noticed that when an opportunity came she drew her chair as near to the fire as possible, and concluded that the cause of her complaint was over-heating, and not cold. Now that fires are discontinued the oedema is quickly lessening and the erythema disappearing without any local or other treatment.

I was present at the meeting of the Dermatological Section of the Royal Society of Medicine when the two cases of erythema referred to by Dr. Parkes Weber were shown, and the case of my relation was exactly like them. Curiously, a visitor friend at this meeting remarked, when he saw these cases, that they had been sitting too near the fire. I have since made inquiries and discovered two sisters who have suffered from a similar complaint, one mild and the other severe, and both were in the habit of sitting as close as possible to the fire.

Thus it would appear that this complaint is more common than it is supposed to be, and it is not thought serious enough by the sufferers to seek medical advice. I recall the fact that our grandmothers were in the habit, when the chance occurred, of sitting close to the fire and drawing their skirts above the ankle only. Thus they were saved from erythema by their longer skirts and thicker stockings.—I am, etc.,

Twickenham, June 15th.

G. F. GUBBIN.

SIR,—In his interesting article Dr. Parkes Weber directs attention to the changes which time may bring about in the nature of the diseases that a doctor may be called on to treat. We often hear of the part played by fashion in the theories and methods of the doctors, but we sometimes hardly recognize how much fashion plays in the etiology of the diseases they have to treat. We have evidence of the influence of fashion in the troubles produced by small boots and shoes, high heels, etc., and in the now well recognized forms of dermatitis from cheap furs; but it is well that Dr. Weber should have emphasized how recently there has been prevalent a form of erythema of the legs, due probably to the wearing of silk stockings, together with the fact that skirts are now worn short.

I personally have seen a good many cases, chiefly among girls of the working classes. The stockings worn by many of them are of the thinnest and flimsiest kind, with little heat-retaining qualities. The symptoms begin practically like chilblains, sometimes in localized patches, sometimes as a more diffuse hyperaemia or erythema, and if it continues a certain amount of induration is added to the congestion. The part of the leg affected is from the knee to the ankle, probably more frequently in front, but extending also round the limb, as described by Dr. Weber.

It has been seen most frequently after a spell of cold, frosty, or damp weather, dampness having, I think, something to do with it as well as cold. It rapidly diminishes or disappears when the weather gets warmer. One probable cause of its aggravation I do not notice mentioned by Dr. Weber. I believe that it is often aggravated, if not actually produced, by the habit some girls have of sitting close up to the fire, letting the fire warm the fronts of their shins when they come indoors with chilled legs. Heating frozen skin undoubtedly aggravates, if it does not cause, chilblains, and this condition is practically a chilblain, and occurs in the same type of circulation liable to chilblains. It is much benefited or cured by wearing woollen stockings in cold weather, and the cure is hastened by resting at the same time.

With regard to chlorosis, one cannot but be struck with the great decline of its incidence in recent years. When I started practice, about forty years ago as an assistant in an industrial town, a large number of the girls one had to treat suffered more or less from a degree of chlorosis, and we know how common it was in hospitals in the days when I was house-physician. I believe that the great diminution in the number of cases has shown that probably fashion, in the form of the tight corset, as stated by Dr. Weber, had much to do with it. I remember, some time in the late eighties, Sir Andrew Clark pointed out how much constipation probably had to do with its causation, this constipation itself arising often from an undue modesty in girls who, after puberty, failed to develop the habit of seeking an opportunity for regular evacuation. The condition was very common among domestic servants, and probably their ill ventilated sleeping rooms had to do with this. In addition to giving up the tight corset the rapid growth of the cult of fresh air and healthy exercise in girls before the usual date of onset of chlorosis, as well as after, has had much influence. In these days girls, in developing into young ladies, became less and less free and natural in their life and movements. The diminution in chlorosis and the appearance of this erythema of the legs are therefore, at least in part, alike due to a change in the life and habits of girls.—I am, etc.,

Leith, May 30th.

WILLIAM ELDER, M.D.

#### ULTRA-VIOLET LIGHT.

SIR,—Dr. P. Redington Peacock does me the honour of criticizing my letter published in your issue of June 6th. My communication was written with the intention of stimulating inquiry and provoking criticism, preferably from workers of experience in this field. The strictures I passed upon mercury vapour lamps in general are the result of my own experience as well as that of others. Perhaps when Dr. Peacock has got beyond the "experimental" stage to which he refers, and has gained some clinical experience, he will have cause to modify his present opinions.

He compares a paragraph which he has extracted from my book (p. 19) with another paragraph extracted from my letter, quite regardless of the context. If he will again refer to my book he will find that the quotation he makes is from a chapter headed "Heliotherapy," and refers to the action of sunlight and not to ultra-violet light.

In a new branch of therapy one is daily gaining knowledge and experience, and is therefore continually modifying one's views. Since I wrote my book I have given many thousands of exposures to hundreds of patients, and I feel I am now in a position to state categorically what a year ago I did little more than hint at. Dr. Peacock may rest assured, as also the members of the Royal Society of Medicine, that my conclusions are based entirely on the results of my own work and experience, and are quite independent of the work of others.—I am, etc.,

London, W.1, June 13th.

PERCY HALL.

SIR,—I note that a correspondent advocates the use of the tungsten arc lamp as giving the best ultra-violet output. It is admittedly a good ultra-violet lamp, but so is the quartz lamp—and with this difference, that the

tungsten are lamp costs £300 per 1,000 hours worked, while the equally efficient quartz lamp costs but £2 10s. for the same number of hours.—I am, etc.,

Brixham, June 13th.

A. BLAKISTON.

### A COMPARISON OF DRIED, EVAPORATED, AND FRESH COW'S MILK.

SIR,—Miss G. A. Hartwell, D.Sc., in her article on the comparisons of the feeding value of various milks (June 13th, p. 1073), states that the fresh cow's milk she used was bottled. The greater proportion of fresh cow's milk sold in London is pasteurized. Even if the milk used was not pasteurized the heating of it to 70° C. interferes with its properties.

The only guarantee of real fresh cow's milk is to purchase Certified, Grade A tuberculin tested, or Grade A milk, as these milks are issued under a licence from the public health authorities, and the date of milking is on every bottle.

In any case the conclusions drawn from these experiments are therefore based on cow's milk heated to 70° C., and not on fresh cow's milk.—I am, etc.,

Reading, June 15th.

G. MADDOCK, C.I.E.,  
Lieut.-Colonel I.M.S.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons debated the Finance Bill in Committee this week on Monday, Tuesday, and Wednesday, without making any large amendments.

The Medical Committee of the House of Commons on Monday night received a deputation from the Section of Anaesthetics of the Royal Society of Medicine, which came to discuss the difficulties arising from coroners holding inquests in all cases of death under anaesthetics, and from the publicity given by the press to such fatalities compared with that given to other deaths during or subsequent to operations. The deputation suggested that a scientific inquiry into death under anaesthetics might be more useful than an ordinary inquest. The Medical Committee asked the deputation to formulate specific proposals. During the discussion it was suggested that the anaesthetists should see whether a clause could be drafted for addition to the forthcoming Coroners Bill, and some members of the committee declared their belief that the publicity given to such mishaps was valuable.

It was mentioned that six medical members of Parliament were about to go to Geneva to see the preparation of M. Spaulinger's antituberculosis serum and to examine the records of its use. The Medical Committee will take no action until these members return and report. They are not making the journey as official representatives of the committee. The committee received a report that Dr. Fremantle and Sir Richard Luce had seen the War Secretary, Sir L. Worthington-Evans, and were in correspondence with him with regard to complaints of the failure of the Government to carry out its promises to the senior majors of the R.A.M.C., and also with regard to the causes underlying the shortage of candidates for commissions in the corps. Representations may later be made to the Army Committee of the House of Commons on the subject.

The Medical Committee agreed that arrangements should be made early next session for a meeting, to which the whole House would be invited by the Medical Committee, for the purpose of hearing a complete statement of the case for the efficiency of vaccination as a personal safeguard, this matter being kept separate from the case for compulsory vaccination. During a brief discussion on compulsion it was pointed out that the Parliamentary Labour Party, including those Labour members who are personally convinced of the efficacy of vaccination, is opposed to compulsory vaccination.

**Bethlem Hospital Bill.**—In the House of Lords, on June 16th, the Bethlem Hospital Bill was read a second time without a division. The bill authorizes the Corporation of the City of London to sell the site of the hospital, at present let at a nominal rent to the governors, and to use the proceeds to erect a new hospital on a large estate which has been acquired in Surrey, to the south of Croydon. The new site will afford space to put into operation the newer methods for the treatment of the insane for which the present site in Southwark affords no adequate opportunities.

**Medical and Sanitary Administration in the Colonies.**—Tables supplied to Colonel Angus McDonnell by the Colonial Secretary show that in 1901 Trinidad spent £18,926 on its staff of medical men and in 1924 £30,034. The total cost of administration of medical and sanitary services in 1901 was £76,947, and in 1924 £152,781. Hong-Kong in 1901 spent 30,155 dollars on its staff of medical men, and in 1924 170,246 dollars. Its total medical and sanitary expenditure in 1901 was 283,127 dollars, and in 1924 1,273,640 dollars. The Gold Coast spent £15,708 on its staff of medical men in 1901 and £63,165 in 1923-24, while its total medical and sanitary expenditure in the first year was £30,293 and in the second £236,506. In 1901 none of these colonies provided specially for medical research. In 1924 Hong-Kong set aside 59,341 dollars for it, and the Gold Coast £7,348 in 1923-24.

**Small-pox in Colombo.**—Answering Mr. Bromfield, on June 16th, Mr. Amery said that 629 cases of small-pox had been notified at Colombo during the period 1915 to 1924 inclusive, and 163 deaths had occurred. The available reports did not always particularize between vaccinated and unvaccinated cases, but of the 21 deaths which occurred in Colombo in 1920, the year in which there was the heaviest mortality since 1915, 3 occurred in children who had never been vaccinated and 16 in cases showing no evidence of primary vaccination, though they were said to have been vaccinated in childhood. Of the 24 cases which occurred in Colombo in 1923, 14 had no visible marks of vaccination and 8 were unvaccinated. No further particulars were at present available.

**Drugs on Ships.**—Mr. Lougher, on June 16th, asked the Minister of Health whether, in respect of the issuing of certificates to enable masters of vessels to replenish their supplies of drugs scheduled under the Dangerous Drugs Act, 1920, the forms necessary for granting certificates would be drawn up in such a manner as to be fully understood by the masters of foreign vessels; and whether more adequate arrangements would be made by the Ministry to facilitate the detection of concealed drugs upon foreign vessels entering the various ports of the United Kingdom. Mr. Locker-Lampson (Under Secretary to the Home Office) said that the regulation did not prescribe the use of any form. Under the regulation all that the master had to do was to apply to the port medical officer, who was authorized to give him a certificate for such quantity of drugs as might be needed until the ship next reached its home port. He had no reason for supposing the present arrangements to be inadequate.

**Overdose of Strychnine.**—On June 16th Colonel Day asked a question about a recent case at the Billericay isolation hospital, Essex, where a patient named Joseph Drage died as a result of the administration of an overdose of strychnine by a temporary unqualified nurse; and if he would take such action as would allow of only fully qualified nurses being allowed to administer poisonous medicines to patients undergoing hospital or institutional treatment. Sir Kingsley Wood (Ministry of Health) said that the Minister of Health had communicated with the Billericay Rural District Council, to whom the hospital belonged. He had no control over the internal administration of isolation hospitals, but was informed that the district council was taking all possible steps to prevent the recurrence of such a regrettable accident. Colonel Day asked whether the Minister of Health could enact that when unskilled persons had to dispense poisons the medicine could be made up in phials of one dose each. Sir Kingsley Wood replied that these cases were very occasional, and that the Ministry of Health had no power to make such regulations.

**Vaccination.**—The Minister of Health is awaiting a report from the Lambeth Board of Guardians into the case of twin girls, aged 10 months, who are alleged by Colonel Day to have been vaccinated shortly after admission to the institution, although the father had obtained a certificate of exemption from vaccination in respect of both children. Colonel Day further alleged that one child died after the inoculation, the other still being an inmate of the infirmary. The Colonial Secretary, Mr. Amery, informed Mr. Compton that although vaccination was compulsory in Southern Nigeria and might be enforced in particular areas of Northern Nigeria when deemed necessary, it was impossible to enforce the Ordinance strictly, and the vaccinations performed between 1913 and 1923 were only 1,890,237 in a population of over 18,000,000. Registration of deaths was not, and could not be made, compulsory, so the approximate number of deaths from small-pox could not be given. There died in hospital in Nigeria from small-pox 30 persons in 1919, 341 in 1920, 182 in 1921, 97 in 1922, and 44 in 1923, but these figures were known to bear no relation to the total mortality.

**Trypanosomiasis.**—Answering Sir Sydney Henn, Mr. Ormsby-Gore said the Colonial Secretary hoped that the proposals would be approved for the dispatch of an expedition to Uganda under the general direction of the Duke of the East African Medical Researches into the problem of the side of the problem. The Colonial Secretary trusted it would prove possible to arrange a more comprehensive campaign for the destruction of tsetse fly in the British dependencies of tropical Africa on the lines contemplated in the report of the East Africa Commission.

**Information on Birth Control.**—The Minister of Health informed Mr. Thurtle that he had received a resolution recently passed by a conference of Labour women asking that medical officers at maternity centres should be allowed to give information on birth control to married women who desired it. He agreed with his

predecessors that institutions provided at the cost of public funds should not be used for so controversial a purpose without express directions from Parliament. He considered, however, that women attending maternity or infant welfare centres who, on medical grounds, appeared to need information on birth control should be referred to a private doctor or to a hospital.

**Boron Preservatives.**—Answering Mr. Whiteley on June 15th, Mr. Neville Chamberlain said that the harmfulness of boron preservatives was thoroughly considered by the Departmental Committee which inquired into the subject. Its report showed that boric acid in small doses had been known to produce ill effects, and that in continued doses it was likely to impair the health of the consumer.

**Parasites of Insect Pests.**—On June 15th, Mr. Cadogan asked whether the experiment of breeding beneficial parasites with a view to fighting insect plagues in our overseas dominions had proved a success. Mr. Ormsby-Gore (Under Secretary for the Colonies) replied that the Director of the Imperial Bureau of Entomology reported that during the eighteen months in which this experiment was being carried out two successful introductions of beneficial parasites were effected. A New Zealand parasite of the pear-slug was introduced from Nyasaland into Nigeria with a view to control of *Glossina turbinoides*, a species of tsetse fly prevalent in Nigeria. Two parasites of the earwig had also been introduced into New Zealand, but owing to difficulties in rearing them in the laboratory there the strains had died out. This work had been suspended, but it was hoped to resume it shortly.

**Veneral Disease in the Straits Settlements.**—On June 15th, in reply to Mr. Pethick-Lawrence, who asked whether the Legislative Council of the Straits Settlements had submitted a draft bill embodying any of the proposals of the committee appointed to investigate the spread of veneral disease there, which recommended in favour of the licensing and registration of all brothels by a Government official to be called the Controller, and the submission to a weekly medical examination of all prostitutes, Mr. Ormsby-Gore replied that a draft bill had been received from the Governor of the Straits Settlements, which embodied the proposals of the committee referred to. The bill had been under consideration by the Advisory Committee on Social Hygiene, and he was now awaiting its report.

#### Notes in Brief.

For advertisements of soap on the back of the current issue of notices of the requirement of vaccination, £135 was received. It is not intended to continue this means of raising revenue.

In 1923-24 the estimated gross expenditure of local authorities in England and Wales for milk for mothers and children was £285,900, and the estimated net expenditure £175,000.

In the first quarter of 1924 West Ham supplied 61,625 lb. of dried milk to mothers and children, but no liquid milk; Poplar, 3,733 lb. of dried milk and 139,974 pints of liquid milk; Birmingham, 17,772 lb. of dried milk, but no liquid milk.

The Government has decided to set up a Food Council as recommended by the Royal Commission on Food Prices.

Early steps are to be taken for the re-establishment of the Amami Institute in Tanganyika Territory, and for its upkeep as a centre of scientific agricultural research.

Commander Kenworthy has presented a petition from 1,606 residents in Brighton and Hove against vivisection.

On January 1st, 1924, 203,757 persons were in Poor Law institutions, of whom 19,965 were insane.

Officers of the Ministry of Health are giving constant attention to the question of providing separate accommodation for children outside workhouses where boards of guardians have not already provided this.

The Government cannot undertake legislation to enable the guardians to take legal proceedings, prior to the birth of an illegitimate child, against the putative father, for the expenses of the mother's confinement.

On June 15th, the Secretary for Air stated that no officer or airman would be allowed to carry out a practice parachute jump from an aeroplane until he possessed considerable air experience. It was clearly laid down in regulations that such jumps were only to be made by volunteers.

The Home Secretary informed Colonel Day that he is looking into the police regulation which, when a person is in custody on a charge of being drunk while in charge of a motor car, does not permit that person to be examined by a doctor called by anyone other than himself.

No issues of medical importance have yet been raised in Grand Committee on the Public Health Bill.

No reputed cure for tuberculosis in cattle has been submitted to the Government for testing.

In the recent outbreak of poisoning in the York and Lancaster Regiment at Cologne no soldiers died. The War Office is awaiting a report.

On January 1st last 10,489 children were boarded out by Poor Law authorities in England and Wales. Ten women inspectors are

## Obituary.

We regret to record the death of Dr. SAMUEL DONN CLIPPINGDALE, who before his retirement had practised for many years in Kensington, and was a familiar and respected figure in London medical circles. He was educated at the University of Aberdeen and the London Hospital, and obtained the diploma of M.R.C.S. in 1875. He graduated M.B., C.M. Aberd. in 1876, and M.D. in 1879, and became F.R.C.S. Eng. in 1880. He had served as prosector at the Royal College of Surgeons and house-physician to the London Hospital, and was for a considerable period surgeon to the Kensington Dispensary and Children's Hospital. Dr. Clippingdale was a diligent student of historical and antiquarian matters. He had held office as president of the West London Medico-Chirurgical Society, and was a former vice-president of the Section of Bacteriology and Climatology of the Royal Society of Medicine. His medical-literary turn of mind and the industry with which he worked up historical material were shown in the papers he published in the BRITISH MEDICAL JOURNAL. These were a Medical Roll of Honour of Physicians and Surgeons who remained in London during the Great Plague, which appeared in 1603; a Medical Parliamentary Roll, 1558-1910, published in the following year; and an article on Medical Baronets, 1654-1911, published in 1912. He contributed also to the *London Hospital Gazette* a large number of biographical sketches of past members of the medical and surgical staffs of that institution, and had published several papers on the climatology of London and its environs.

Dr. WILLIAM LESLIE, who died in Edinburgh on May 29th, was born in 1865. He received his medical education at Edinburgh, graduating M.B., C.M. in 1894, and proceeding M.D. in 1907. Dr. R. A. Fleming writes: His love of surgery induced Dr. Leslie to become a Fellow of the Royal College of Surgeons of Edinburgh in 1908, and as one of the surgeons to the Clackmannan Hospital his surgical dexterity had free and successful scope. He practised in Alloa for thirty years, where he speedily acquired a large and ever-increasing practice. Dr. Leslie will be long remembered, not merely for his professional skill, but also for the friendship and for the confidence inspired in his patients. For a long time he had suffered from the effects of high blood pressure, unquestionably due in part to the anxious solicitude he bestowed on his patients. A severe attack of pneumonia subsequently necessitated his retirement for a prolonged rest. He had come to Edinburgh for medical advice, when his death from angina pectoris occurred with tragic suddenness. Our sympathy in full measure goes out to his widow, whose care and devotion enabled Dr. Leslie to continue his work in spite of considerable and increasing physical difficulty. Dr. Leslie was laid to rest at Alloa on June 2nd, among those whom he had so long served as physician and friend.

Dr. JOHN KENDALL, who died on May 22nd at Coniston, Lancashire, at the age of 71, came of a well known local family, the Kendalls of Cockenshell, Blawith. Dr. Kendall was educated at Anderson College, Glasgow, and obtained the diplomas L.R.C.P. and S.Ed. and L.M. in 1875. After filling the appointment of house-surgeon at the Glasgow Royal Infirmary he began practice in Coniston. He was a member of the British Medical Association and was a justice of the peace for Lancashire. A colleague writes: Dr. Kendall belonged to the finest type of country practitioner. He had a wide experience of the surgery of accidents, particularly in connexion with the quarries on "Coniston Old Man" and "Tilberthwaite," and there are many men now walking about Coniston sound in health who have to thank him for his skill and devotion. He was a loyal friend and true colleague; no petty thought ever came into his mind. He was the soul of honour, and his devotion and kindness to his patients set a fine example to his fellow practitioners. That this was appreciated was well shown by the large number of sorrowing friends who attended the funeral on May 25th at the little church where he had been for many years churchwarden. Dr. Kendall retired

about eighteen months ago, since he found the work becoming rather too much for him in what is, geographically, probably one of the most difficult practices in England. Even in his retirement he took a lively interest in the affairs of the village where he had been in practice for forty-eight years. He leaves a widow, two daughters, and a son (in the medical profession) to mourn his loss.

## Medico-Legal.

### ALLEGATIONS OF NEGLIGENCE REBUTTED.

#### INMAN v. TANNER.

IN a High Court action, brought on May 20th and 21st by Mrs. Nina Inman of Bayswater against Mr. Herbert Tanner, F.R.C.S., for damages under Lord Campbell's Act, on the ground that the death of her son, Cecil George Inman, aged 24, was due to the negligence of Mr. Tanner, the special jury, after hearing Mr. Tanner's evidence, stopped the case and gave a verdict in his favour, the Lord Chief Justice adding that he entirely concurred in the verdict.

The deceased was a panel patient, and, prior to the hearing of the case in the High Court, Mrs. Inman's complaint was dealt with under the National Insurance Acts. The Medical Service Subcommittee—the medical members, however, recording their disagreement—found the case proved against Mr. Tanner, and severely censured him, and Mr. Tanner's appeal to the Ministry of Health was dismissed—save in respect of one particular finding of fact—the Ministry stating that the question of the sum to be deducted would be deferred until after the hearing of the High Court action. An officer of the Ministry present at the hearing of the appeal was also present at the hearing in the High Court. The Ministry has not yet made its decision known.

The case against Mr. Tanner was that he diagnosed a case of diabetes mellitus as one of cerebro-spinal meningitis and so failed to treat the deceased properly; that he failed to visit the deceased one night when informed of the patient's condition; and that he did not make any examination of the deceased's urine; further, that he failed (a) to make or cause to be made a lumbar puncture or examination of the spinal fluid, (b) to examine the optic discs, (c) to give sodium salicylate or potassium sulphate, (d) to give Flexner's antimeningeococci or any other serum, (e) to order a sufficiently low or liquid diet.

Sir Reginald Coenry, K.C., and Mr. Eric Sachs (instructed by Messrs. Judge and Priestly) appeared for the plaintiff, and Mr. J. A. Hawke, K.C., and Mr. T. F. Davis (instructed by Messrs. Buleraig and Davis) appeared for the defendant, who denied negligence and damage.

The plaintiff's evidence was to the effect that her son had not been well from January, 1924, and first visited Mr. Tanner on April 14th, 1924. He was getting thin, passed much urine, and was very thirsty. After a few surgery visits the deceased grew worse, and was visited at his home by Mr. Tanner on May 10th, 12th, and 14th. She showed Mr. Tanner the quantity of urine passed in a night, and she said the doctor said it was normal. On May 10th Mr. Tanner certified the deceased to be suffering from bladder irritability, and ordered him to be kept warm and to be given a little nourishing diet, not much meat. On May 12th her son went "boss-eyed." On the night of May 14th Mr. Tanner was informed that the patient was sick, and he ordered that ice be sucked and soda water drunk, adding that he would call in the morning. She agreed that the doctor was not asked to call that night. The deceased, however, became unconscious late that evening, and Dr. Goldfoot was called in. He diagnosed diabetic coma, and sent the deceased to Paddington Infirmary, where he was treated with insulin. To this treatment there was no response, and death occurred at 2 a.m. on May 16th, 1924.

Dr. Goldfoot, in his evidence, said that polyuria, glycosuria, and wasting were signs of diabetes, but that sugar in the urine could be present from meningitis, and that as (1) the doctor had examined the urine on April 23rd or April 28th and found no sugar, (2) there was no reaction from the injection of insulin, (3) the deceased had gone "boss-eyed," it was reasonable for Mr. Tanner to come to the conclusion that the deceased was suffering from meningitis.

Dr. Conolly, resident medical officer at the Paddington Infirmary, said he certified the cause of death to be diabetes mellitus. A post-mortem examination was made, but the brain and spinal cord were not examined. A specimen of the urine was taken, and showed sugar present. The presence of sugar was not conclusive of diabetes, and when he gave the death certificate he was not aware that the deceased had gone "boss-eyed." Coupling that fact with the lack of response to insulin, there was a possibility of cerebral trouble.

Dr. A. S. Woodcock said if Mr. Tanner examined the urine and found no sugar, and was unaware of polyuria and great thirst and wasting, he was quite reasonable in excluding diabetes. Sugar could be present in the urine from brain trouble, and in diabetes there was generally a response to insulin treatment.

Mr. Tanner, in his evidence, said that on April 23rd or April 28th he examined the urine and got no reaction for sugar. The patient was dull and lethargic, but he found no signs of wasting. The urine passed in one night was normal, both in quantity and colour. He was not surprised at the fact that the deceased was

a little thirsty, because he had been prescribing diuretics. By May 14th he was very suspicious that the case was cerebro-spinal meningitis, and decided that if there were no change by May 15th he would send the deceased to hospital. On calling the next day he found the deceased had been removed. He was still of opinion that the deceased did not die of diabetes mellitus, but from meningitis.

Before the hearing in the High Court, the Ministry of Health, in dismissing Mr. Tanner's appeal to it, said:

"We cannot escape from the conclusion that the presence of diabetes mellitus was excluded upon insufficient grounds, and, further, that, having regard to the very serious suspicions present in his mind, Dr. Tanner was at fault in omitting to take active steps either to confirm or dispel them. While we fully recognize the frequent necessity for keeping a doubtful case under observation, we feel that the period of observation, pure and simple, unaccompanied by active investigation, should be kept within reasonable limits, and that in this case even if Dr. Tanner had not recognized the need earlier, yet in view of his serious suspicions the onset of an increasingly acute condition on and after May 10th should have indicated the urgent necessity of making an immediate attempt to clear up the real nature of the case by all available means (for example, further tests of urine, lumbar puncture, examination of the optic discs, second opinion, removal to hospital). The failure to take any of these courses, some of which, as the doctor's own evidence showed, he had in mind, constitutes, in our opinion, something more than an error of judgement on his part."

They did not think the fact of the patient being sick, without the disclosure of the fact that the patient was also in a state of coma, was sufficient ground for the allegation that the doctor refused to respond to a summons for help on the night of May 14th.

"On the other hand, we agree in this respect with the view taken by the subcommittee, that whatever the terms of the message the doctor should have gone to the patient. . . . The peculiar significance attaching to a lethargic condition in diseases of the central nervous system is, in our view, an additional reason for his responding to a message which gave any indications of the onset of fresh symptoms whatever its terms."

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

THE Professor of Anatomy has reappointed Dr. A. B. Appleton, Mr. D. G. Reid, Mr. A. Hopkinson, and Mr. V. C. Penell as demonstrators of anatomy.

The congregation for conferring degrees in medicine and surgery has been postponed from July 14th to Tuesday, July 21st.

### UNIVERSITY OF BRISTOL.

AT 9th, in connexion with the opening by University buildings, the Chancellor a number of honorary degrees were conferred on the LL.D. on Sir George Osley, architect of the new building; the D.Litt. on Sir Henry Hadow, Vice-Chancellor of Sheffield University; and the D.Sc. on Sir Richard Gregory, F.R.S., Editor of *Nature*, and Sir John Herbert Parsons, F.R.S., F.R.C.S., both natives of Bristol.

### UNIVERSITY OF MANCHESTER.

THE Council of the University has accepted the resignation of Dr. J. M. W. Morrison, lecturer in applied anatomy, on his appointment to the lectureship in radiology in the University of Edinburgh.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on June 11th, when the President, Sir John Bland-Sutton, was in the chair.

The congratulations of the Council were offered to the President on having received the honour of a baronetcy and to Sir James Berry on having received the honour of knighthood on the occasion of His Majesty's birthday.

### Diploma of Fellowship.

Mr. J. Basil Hall, President of the British Medical Association, was introduced and admitted a Fellow of the College. Diplomas of Fellowship were granted to the following twenty-four candidates:

A. C. B. Biggs (Univ. Coll.), G. . . . .	rajkar,
I.M.S. (Bombay and St. . . . .	ll. and
St. Bart's), K. N. Purkis . . . . .	nias's),
	larnett
	Coll.),
	hart's),
	so and
	and Lond.), M. Geaney
	l), J. B. Oldham (Liver-
	W. M. Cotter (Otago and
	s), A. Rugg Gynn (Edin.
	St. Bart's).

### Lectures and Demonstrations.

The following Professors and Lecturers were appointed for the ensuing year:

*Hunterian Professors.*—Sir Arthur Keith: Six lectures on the Evolution of the Higher Primates. Arthur Edmunds, C.B.: One

## MEDICAL NEWS.

lecture on Pseudo-hermaphroditism and Hypospadias and their Surgical Treatment. J. E. Adams: One lecture on Malignant Disease of the Jejunum. E. Musgrave Woodman: One lecture on the Surgical Treatment of Phthisis and Bronchiectasis. A. Lawrence Abel: One lecture on the Treatment of Cancer of the Oesophagus. Hugh William Bell Cairns: One lecture on Neoplasms of the Testicle. Stanford Cade: One lecture on Cholera and Gale Lecturers. Two lectures on the Importance of cystography. Alfred Piney: Six demonstrations in Haematology in Surgery. Erasmus Wilson Lectureship.—Clement E. Sbattock: Six demonstrations on Surgical Pathology. Sir Arthur Keith: Six demonstrations on the contents of the Museum.

## Board of Examiners.

The following were elected as members of the Board of Examiners in Anatomy and Physiology for the Fellowship for the ensuing year: Anatomy: William Wright, Frederick Gymer Parsons, Wilfred Edward Le Gros Clark, Cecil P. G. Wakeley. Physiology: John Mellanby, David Henriques de Souza, Frangcon Roberts, John B. Leathes.

## The following were elected examiners under the Examining Board in England for the ensuing year:

Elementary Biology: Thomas William Shore, James P. Hill. Anatomy: Henry A. Harris, Oscar S. Hillman, John Basil Humo. Physiology: Charles A. Lovatt Evans, George A. Buckmaster. Midwifery: Charles H. Roberts, Eardley L. Holland, Donald W. Roy, Harold B. Whitehouse. Diploma in Public Health: Part 1, Richard Tanner Hewlett; Part 2, Francis J. Stevens. William P. MacArthur; Diseases and Hygiene of Tropics, Philip H. Maunon. Diploma in Ophthalmic Medicine and Surgery: Part 1, Sir John Herbert Parsons, Charles B. Goulden; Part 2, Malcolm L. Bahr. Diploma in Psychological Medicine, Messrs. C. H. Hephurn. Diploma in Laryngology and Otology: Part 1, Herbert Tilloy, Arthur H. Cheattle; Part 2, Herbert J. Marriage. Messrs. C. H. Fagge, L. B. Rawling, H. S. Clogg, H. Lett, and T. P. Legg were elected members of the Board of Examiners in Dental Surgery for the year ending June 30th, 1926. The following of the Board of additional members of the Dental Section of the Board of Examiners in Dental Surgery: Ernest Blair Dowsett, D.S.O., Arthur Thomas Pitts, D.S.O. Mr. Graham Simpson of Sheffield was elected a member of the Court of Examiners in the vacancy occasioned by the resignation of Mr. A. P. Dodds-Parker.

## ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the June meeting of the President and Fellows the following were admitted Licentiates and Members of the College: C. A. Nadicarianda, J. S. Quin.

## The Services.

## INDIAN MEDICAL SERVICE.

Warrant Governing Age of Retirement of D.M.S. With reference to Army Department Notification No. 2649, dated August 15th, 1919, the Governor-General in Council March 17th, 1925, publication of the following Royal Warrant, dated March 17th, 1925, regarding the age for compulsory retirement of an Indian Medical Service officer holding the appointment of Director, Medical Services in India:

George R.I.  
Royal Warrant.  
Whereas we deem it expedient in the interests of the Service to make the following change as to the age at which officers of our Indian Medical Service holding administrative appointments shall be placed on the Retired List.  
Our Will and Pleasure is that an officer of our Indian Medical Service holding the appointment of Director of Medical Services in India shall be placed on the Retired List on attaining the age of 60.  
Our Warrant dated 13th June, 1919, shall be amended accordingly.  
Given at Our Court, at St. James's, this 17th day of March, 1925, in the fifteenth year of Our Reign.  
By His Majesty's Command.

(Sd.) BIRKENHEAD.

## DEATHS IN THE SERVICES.

THE LAST MEDICAL SURVIVOR OF THE INDIAN MUTINY. Bengal Deputy Surgeon-General Philip Warren Sutherland, aged 93. He was the son of Adam Sutherland, surgeon, of Hayes, Middlesex, and was educated at King's College Hospital. After taking the M.R.C.S. in 1853, he entered the rank of deputy surgeon-general in May, 1854. He attained the rank of deputy surgeon-general in December, 1883, and retired on February 5th, 1889. He served in the Indian Mutiny in 1857-58, and received the medal. His whole service was spent in military employ, winding up with five years as assistant medical officer of the Clarence Cooper. Since the death of Sutherland had been the senior member of the I.M.S. retired list. That distinction now falls to Surgeon-General Henry Cook, of the Bombay Service. More interesting, however, is the fact that Sutherland appears to have been the last medical survivor of the Mutiny. There are still two retired officers of the I.M.S. living who were in India during the Mutiny—

Surgeon-General H. Cook and Surgeon-Major A. Gamack—who neither of them served in the field during the campaign. The last surviving Mutiny veteran of the Army Medical Department seems to have been the late Surgeon-Major A. E. T. Longhurst, who died on March 20th last.

Lieut.-Colonel Alfred Henry Williams, Bengal Medical Service (ret.), died at Eastbourne on May 20th, aged 78. He was the son of the late Henry Williams of Longford, and was educated at Aberdeen, where he graduated M.B. and C.M. in 1871, and at St. Thomas's, taking the M.R.C.S. in 1872. He entered the I.M.S. as assistant surgeon in March, 1872, became lieutenant-colonel after twenty years' service, and retired in 1897. His entire service was spent in military employment, for the greater part of the time in the 9th Bengal Infantry, one of the Company's old "Parade" regiments, which was disbanded in 1834, and re-raised as a Gurkha battalion, with the 9th he served in the Afghan war in 1880, and received the medal.

Captain Cyril Armand Bernard, M.C., R.A.M.C., died suddenly at Cologne on May 10th, aged 36, while acting as wicketkeeper in a cricket match. He had joined at Cologne, from India, only five days before. He took the diplomas of L.R.C.P. and S.E.d. and L.R.F.P.S.G. in 1914. He received a temporary commission as lieutenant R.A.M.C. on August 12th, 1914, just a week after war was declared, became captain after a year's service, and took a permanent commission on February 12th, 1918. He served in the recent great war, was mentioned in dispatches in the London Gazette of September 22nd, 1916, and received the Military Cross on that date.

## Medical News.

THE report of the Commanding Officer of the Corps of Commissionaires, presented to the annual meeting of the governors on June 13th, contained a reference to the death of Dr. Haslip last November. In him the corps, it was said, had lost a medical officer whose exceptional qualities as a physician and a friend of admirable judgement had been of the highest value to the corps for thirty years.

THE Albert medal has been awarded by the Council of the Royal Society of Arts to Lieut.-Colonel Sir David Prain, C.M.G., C.I.E., F.R.S., I.M.S.(ret.), "for the application of botany to the development of the raw materials of the empire." The medal was instituted in 1853 by the society as a memorial of the Prince Consort, who was its president for eighteen years, and is awarded annually "for distinguished merit in promoting arts, manufactures, and commerce."

In order to draw the attention of overseas visitors to its appeal for the Nurses' Home as a memorial to the nurses of the overseas nursing services who died in the war, the Elizabeth Garrett Anderson Hospital is showing a modern operating theatre in the Palace of Transport and Housing at the Wembley Exhibition. We have already mentioned that the names of ninety-seven overseas nurses will be inscribed in the home, and that donations may be sent to the Dowager Marchioness of Dufferin and Ava at the hospital, 144, Euston Road, London, N.W.1.

AN assembly of the Faculties of University College, London, will be held on Thursday, July 2nd, at 3 p.m., when the Duchess of Atholl, M.P., Parliamentary Secretary to the Board of Education, will receive the scholars, medalists, and prizemen, and will give an address. Afterwards the new anatomy and physiology building, the College libraries, and the Bartlett School of Architecture, the College of recent discoveries of the British School of Archaeology in Egypt will be open to inspection.

THE annual prize-giving at the London (Royal Free Hospital) School of Medicine for Women will take place on Thursday, June 25th, at 3.30 p.m. The ceremony will be followed by tea in the garden.

THE annual meeting of the Tuberculosis Society will be held on Tuesday, July 7th, at Pritchard's Restaurant, 79, Oxford Street, London. It will be preceded by a dinner at 5s. 6d. a head. Full information can be obtained from the honorary secretary, Dr. Frederick J. C. Blackmore, 138, Herbert Road, Woolwich, S.E.18.

THE Liddle triennial prize of the London Hospital Medical College will be awarded next year for the best essay on the etiology and treatment of primary high blood pressure. Essays in competition must be delivered at the hospital not later than January 30th, 1926.

IN connexion with the visit of the American medical practitioners to London an illustrated booklet was prepared containing a description of the Brompton Hospital for Consumption, and of its sanatorium at Frimley. This contains a short history of the development of the hospital and a detailed account of its activities.

THE bicentenary of Guy's Hospital and the centenary of the Medical School both fall this year. On Monday, June 29th, the Duke of York will visit the hospital and distribute the prizes to successful students. The laboratories, museums, the college, the nurses' home, and the wards will be open to inspection after the ceremony.

THE Fellowship of Medicine announces that Dr. A. F. Hurst will give a lecture on Friday, June 26th, at 5.30 p.m., in the West Lecture Hall, No. 1, Wimpole Street, on the treatment of cholecystitis and the prevention of gall stones. From June 22nd to July 4th the London Temperance Hospital will hold a special course from 4.30 in the afternoon, for the convenience of those in general practice; fee, £1 ls. A course in urology has been arranged by the St. Peter's Hospital from June 29th to July 25th. The Queen's Hospital for Children has organized a two weeks' course from July 6th to 18th. A course in the diagnosis and treatment of nervous diseases will be given at the West End Hospital (out-patient department, 73, Welbeck Street) from July 27th to August 15th. Other special courses in August are a vacation course at the Prince of Wales's General Hospital, Tottenham, from August 3rd to 15th, a fortnight's intensive course at the Queen Mary's Hospital (Stratford), and a urology course, continuing throughout the month, at the All Saints' Genito-Urinary Hospital. Copies of the syllabuses and the programme of the Fellowship of Medicine may be obtained from the Secretary at No. 1, Wimpole Street.

THE next meeting of the Anaesthetic Section of the Royal Society of Medicine will be held at Manchester on Saturday, June 27th, in the Physiological Lecture Room of the University. A discussion on chloroform will be opened by Dr. H. P. Fairlie, and Mr. S. R. Wilson and Dr. S. McSwiney will give a demonstration on the effects of adrenalectomy injections during ether and chloroform anaesthesia. In the laboratories an exhibition will be arranged of physiological methods of investigating acidosis, and of new apparatus for anaesthesia.

SOME time ago (April 25th, p. 811) we announced that the next Voyage d'études médicales to the health resorts of France (organized solely for the medical profession) would take place in September. It has now been arranged that the party shall meet at Vittef at 5.30 p.m. on September 2nd, and during the subsequent thirteen days visit Contrexéville, Martigny-les-Bains, Bourbonne-les-Bains, Bains-les-Bains, Plombières-les-Bains, Luxeuil-les-Bains, Bussang, Gerardmer, La Schlucht, Münster, Colmar, Soultzbach and Soultzmatt, le Linge, les Trois Epais, Aubur, Ribécourt, Chatenols, Barr, Sainte-Odile, le Hohwald, Schirmeck, Strashourg, Niederbronn, Morsbronn, Luxembourg, Mondorf, Thionville, Sierck-les-Bains, Spa, Naucy-Thermal, Sermaleux-les-Bains. The cost has been fixed at 1,150 francs, which includes all expenses throughout the voyage. English doctors desirous of participating are asked to communicate without delay with Madame M. C. Juppé-Blais, representative of the French Spas, at the Office Français du Tourisme, 56, Haymarket, S.W.1.

THE fortieth Balneological Congress was held at Carlsbad, Marienbad, and Franzenbad from April 3rd to 8th under the presidency of Professor Dietrich of Berlin. After an address by the general secretary, Dr. Hirsch, on the German Balneological Society, which now contains 750 members, the following papers, among others, were read: the experimental pharmacology of mineral springs, by Professor W. Wiechowski; combined therapy, by Professor A. Strasser; the influence of radio-activity on metabolic processes in the animal and vegetable world, the effect of baths on the gases of the blood, by Dr. E. Freund; the treatment of diabetes, by Professor von Jaksech-Wartenhorst; the effect of diet cures on hypertension, by Dr. F. Wagener; modern humoral pathology and balneology, by Dr. B. Aschker; the complications of obesity, by Dr. E. Tuszka; and arterio-sclerosis and cardiac failure, by Dr. A. Selig. At the termination of the proceedings it was decided to found a new monthly journal, entitled *Archiv für Balneologie und Klimatologie*. The next balneological congress will be held at Aix-la-Chapelle in April, 1926.

THE Société Française Nationale de Chirurgie has awarded the quinquennial Lannelongue prize, consisting of a gold medal and 5,000 francs, to Dr. George Crile of Cleveland.

ON June 10th Commemoration Day was held at Livingstone College. There was a good attendance, including Sir George Makins, G.C.M.G., Dr. Manson-Bahr, Dr. Whitfield Guinness, and Dr. J. H. Cook. The chair was taken by Dr. Andrew Balfour, C.B., C.M.G., Director of the London School of Hygiene and Tropical Medicine. The Principal, Dr. Tom Jays, made a short statement as to the financial position of the College, showing that about £800 is needed in order to close the current financial year without a deficit. He showed that the need is for more students; if they are forthcoming the financial needs are small, but owing to the lessened numbers entering since the war, and also to much extra necessary expenditure, the financial burden is heavy. He

spoke of the world-wide influence of Livingstone College, the students of which are now scattered in almost every part of the globe. Dr. Balfour said that what had impressed him extremely in his knowledge of the work of Livingstone College was the way in which the students were trained in persistency in their studies and work. In addition to learning something of medicine and surgery, the students also learnt preventive work in hygiene as applied to tropical disease. The Rev. H. Wakefield (Calabar, West Africa) said he had often wondered what would happen if Old Livingstonians all the world over were to send their testimonies of what Livingstone College had done for them. It would not be a story of increased salaries, of promotion to the heads of departments, but a story of gigantic struggles against disease and squalor. Mr. F. Kilbey (Central Provinces, India), a student of the first session, told of his thirty years' work in the mission field and of the work he had been enabled to do through the knowledge he had gained. He had been able to do much in preventing the spread of disease, in outbreaks of plague and cholera, and had alleviated many cases of eye diseases.

THE *Giornale Italiano delle malattie venere e delle malattie della pelle* has changed its title to *Giornale Italiano di dermatologia e sifilologia*.

A DISCUSSION will be held on hereditary syphilis on the occasion of the Congress of the Association of French Gynaecologists and Obstetricians in the first week in October, when the following papers will be read: latent hereditary syphilis, introduced by MM. Leredde, Lesné, Devraigne, and Carle; treatment of syphilis during lactation and early infancy, introduced by MM. Marcel Pinard, Lomairo, and Péhin; preventive treatment of hereditary syphilis, introduced by MM. Millan, Lévy, Spillmann, Solal, and Petges. Further information can be obtained from the French National League against the Venereal Peril, 7, Rue Mignot, Paris VI.

THE forty-ninth session of the French Association for the Advancement of Science will be held at Grenoble from July 27th to August 1st, under the presidency of Professor J. Teissier of Lyons, when the question of duodenal ulcer will be discussed. Further information can be obtained from Professor Teissier, 108, Chemin d'Alais, Lyons.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1**, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the **British Medical Journal** are **MUSEUM 9801, 9802, 9803, and 9804** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are: EDITOR of the **BRITISH MEDICAL JOURNAL**, **Aitology Westcent, London.**

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), **Articulate Westcent, London.**

MEDICAL SECRETARY, **Mediscera Westcent, London.**

The address of the Irish Office of the **British Medical Association** is 16, South Frederick Street, Dublin (telegrams: **Bacillus, Dublin**); telephone: 4737 (Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: **Associate, Edinburgh**); telephone: 4361 (Central).

## QUERIES AND ANSWERS.

### SOURD MILK.

"G. B." writes to ask where he can obtain lactic acid (Bulgarian) bacilli; also for directions how to prepare the milk from day to day, and how often and how much should a patient be given, and at what hours.

To prepare a suitable soured milk it is necessary to start with a good milk supply, as the resultant junket, in great measure, depends upon the quality of the milk. For the sake of safety it is desirable to bring the milk to the boil and to cool down rapidly, thus ensuring an adequate freedom from extraneous organisms. A good commercial lactic acid bacillus tablet, or a liquid culture, is then employed to inoculate the milk, and after carefully covering the vessel incubation is conducted for a period

**VACANCIES.**  
NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 39, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.  
A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 271.

## A British Medical Association Lecture

ON

## THE MEDICAL WITNESS.\*

BY

H. H. JOY, K.C.

I WOULD like to preface my remarks by emphasizing the immenso responsibility which attaches to the medical witness in connexion with cases of every sort in the various courts of justice involving medical evidence. In some instances the medical questions involved are comparatively simple, and the lay tribunal can to a certain extent exercise an independent judgement upon them. But, speaking generally, the doctor is almost in the position of a man who is interpreting for the court from some foreign language, and accordingly it is obviously his paramount duty to be scrupulously fair and frank. I would like to add that, in the opinion of those best qualified to judge, the medical witnesses as a class prove worthy of the high confidence reposed in them. It is interesting to notice in this connexion that the rules of evidence which apply to ordinary witnesses have had to be modified in an important respect in favour of the medical witness. Speaking generally, the ordinary witness may only give evidence as to facts, and from these facts the court draws its own conclusions; but the medical witness is permitted to give his opinion upon the facts which he has observed, or which are submitted to him—that is, he may state what, in his view, is the proper inference and conclusion to be drawn from a given set of facts; in other words, the court entrusts him with the duty of interpreting those facts, and this at once shows what a responsible and powerful position he occupies.

If the nature of the case to which a doctor is called is such as to suggest to him the possibility of ultimately being required to give evidence—it may be before a coroner or a civil or criminal court—he should equip himself from the start for such an eventuality. I advise him therefore in such a case to observe and record most fully everything that he finds. It is surprising how often great importance afterwards attaches to matters which at the time may not have seemed important. A doctor's connexion with a case may begin only at a later stage—namely, when he is asked to examine with a view to being called as a witness; he may probably be furnished with views or theories by the party engaging his services; he should keep an open mind; he should make his examination fully first and then see to what conclusion it leads; if he cannot to his own satisfaction support the case let him say so plainly; if he can, let him be careful to include in his "case note" everything which really affects his conclusion. It may be a long time before he finds himself in the witness-box; and when there he may refresh his memory from his note; but he may also be asked to show it to the counsel for the other side; obviously, if something to which in his evidence he has attached importance is not to be found in the note made at the time, he lays himself open to criticism. As regards the making of the note, dictation will do provided he takes the precaution to initial it, and he should see that it is dated. The note should be made at, or as nearly as possible at, the time of the examination; the witness should have the original note with him. But the doctor should not make a habit of using this "note" too liberally—any "refreshing" should be done before entering the witness-box; a witness is not likely to create such a good impression on the court if he gives the appearance of not knowing the facts.

Not infrequently, I suppose, you may wish to apply certain tests when making an examination, to help you to decide whether a man's condition is really the consequence of an injury or is due to disease; it is not always easy to know what to do. Each case must depend largely, of course, on its own special circumstances, but I think I may say this much at any rate: if there is some test which in your view is really essential to forming a sound conclusion, but is perhaps lengthy and irksome to the patient, you should at least ask him to consent to it, otherwise you may find,

when in the witness-box it is put to you, "Isn't so-and-so an accepted test of the presence of such disease?" you have to say Yes; and when you are asked why you did not apply it, you can say, "Well, I asked permission to do so, but the man objected and I could do no more." It will at any rate show that you were not avoiding it for fear it might have upset your view of the case. Such difficulties are largely, I think, obviated in cases under the Workmen's Compensation Act, because that Act contains provisions for what is in effect a compulsory examination of the man on behalf of the employer, and further provides that if he refuses to submit to or in any way obstructs such examination his right to compensation may be suspended until he has submitted; so in cases under that Act you would report to the employer's solicitors that you were not able to make what you considered a proper examination, and the court would then have to decide whether the man was refusing to submit to or was obstructing the examination. In connexion with examinations under that Act, you may like to know that the House of Lords has held that there is no absolute right in the workman to have his own doctor present at such examination, so if a workman refuses to submit himself unless his own doctor be present, it is for the court to say whether his refusal is reasonable or not; so that from your point of view you need not worry over any questions of etiquette as regards the attendance of the man's own doctor, though doubtless you would seldom raise objection to his being present.

When the case is one where you have to rely mainly or wholly upon subjective symptoms, test the man's credibility during your preliminary examination by such devices as appear best to you, so as to be able when in the witness-box to fortify your conclusions that he was or was not exaggerating his symptoms or perhaps malingering.

Sometimes doctors from either side meet by arrangement of the parties for an examination of the applicant, with the hope of agreeing, for instance, as to whether there is any incapacity or whether the condition is the result of accident or disease, and so saving litigation. This is an excellent thing to do (except from counsel's point of view); but my own personal opinion is that on all such occasions the discussion should by arrangement be "without prejudice," so that neither doctor can be examined or cross-examined, if the case should eventually come to court, as to what was or what was not said by one to the other. The failure to take this precaution has led to some unpleasant personal conflicts of recollection in the witness-box. Do not give your solicitor a stronger report than you can really maintain in the witness-box. For instance, if your report says that a man is a malingerer, there should be no risk of having to climb down and say that he is not intentionally exaggerating. Remember that counsel opens his case largely from your report, and it is a fatal thing to open it too high and see it being painfully brought down. Counsel's brief is almost invariably marked with a fee of 3 and 1, or 5 and 1, or whatever else he can get and 1. The 1 indicates a conference. When circumstances permit make a point of attending that conference; counsel can then get a far better grip of the medical aspects from a talk with you; he can also discuss with you the nature of the points which the other side is likely to put forward, and get your observations upon them. Also do all you can to get hold of the correct version of the facts—a by no means easy task sometimes, but obviously a most essential matter. In hospital cases ask to see the notes; they are not strictly evidence unless produced by the doctor who made them (who has often gone away), but the Court of Appeal has expressed the view that they should be at the disposal of each side. Of course, if in the progress of the case facts new to you come out which cause you to modify or even alter your views you will naturally have to act accordingly if you go into the witness-box; but in such a case take care to let counsel know how the new or altered facts affect your view. I think I can best explain my meaning by an illustration.

You have been called in to examine a case of a man who has some time ago received a blow over the spinal cord, and is now exhibiting symptoms of paralysis; you are told that the blow was at point A, and you see the symptoms of loss

\* Delivered before the South Staffordshire Division, February 3rd, 1925.

of power are in the appropriate parts corresponding with an injury at that precise point; you have therefore concluded cause and effect, and were prepared to give evidence accordingly. During the case the doctor is called who saw the man while the mark of the blow was still to be seen, and he locates it at a spot which would not affect the paralysed part. You cannot, of course, any longer rely upon the opinion you had formed; nor can you give evidence—if you give it at all—without qualifying it by saying that “if the seat of injury was really so high up as Dr. So-and-so says, then I must admit it would not be reflected in the part now paralysed, and therefore is not the cause of it.” Now counsel or the solicitor conducting the case would almost certainly not know what a vital change of affairs would result from Dr. So-and-so’s evidence as to the precise spot, and you must at once explain to him what has happened, or else he will find himself hopelessly involved.

Now let us assume a case has reached the court. You are going to give evidence for the defendant’s side. Please do not think it is enough to be on call by the ‘phone to hurry round when your evidence is wanted. In the great majority of cases it is most essential that you should hear all the evidence, and especially, of course, the medical evidence; you may thus obtain some entirely fresh light upon the matter, and you can then, with your special skill and knowledge, be enormously helpful to your counsel; and further, when you go into the witness-box you will know exactly how the case stands and what you have to meet, and will be forewarned against the line of cross-examination.

As regards the actual giving of your evidence I would make a suggestion or two. Remember that the simpler the language of the expert the greater is his effect upon the court. In a case before a judge and jury a doctor stated in his evidence that “on examining the prosecutor he found him suffering from a severe contusion of the integuments under the left orbit, with great extravasation of blood and ecchymosis in the surrounding cellular tissue, which was in a tumefied state; there was also considerable abrasion of the cuticle.” The judge: “I suppose you mean that he had a black eye?” The doctor: “Yes.” The judge: “Then why not say so?”

Scientific evidence should therefore be as unscientific as possible when given in court. Take care to have ascertained beforehand what the real issues in the case are. I am afraid it does not always occur to those who engage your services that it is necessary for you to know the precise issues, but it almost always is, and you should see that you are fully informed. To take one illustration from an actual case. A man has had nystagmus which has incapacitated him, and he has received compensation. He “recovers,” and his employers claim to stop his compensation, alleging that any incapacity due to “the so-called accident” has ceased. He claims a continuance of the compensation, and it is necessary for him to show that his incapacity (that is, in this case inability to resume work in the mine) is due in one way or other to the so-called accident—namely, the disease of nystagmus. The doctors called on his side agree that he is now free from nystagmus, but say that it will probably recur if he again works below; but they omit to say that the danger of that recurrence is due wholly or partly to the attack that he has had. He loses his case; whereas if they could have said, “There is an increased susceptibility consequent on the previous attack,” the man would have succeeded.

In many of the matters that come into court under the Workmen’s Compensation Act the question is whether the injured man is now sufficiently recovered to do some work. In these cases you are asked to give evidence as to his capacity for work or as to what work is suitable for him; you should therefore ascertain what work it is that the employer is suggesting as suitable, and go and get personal knowledge of the actual work and of the surrounding conditions. Counsel for the man cross-examines you somewhat in this fashion: “Don’t you think for a man with impaired sight the work offered is unsuitable, because of his having to go about where machinery is in motion, or chips flying about?”—or whatever it is. If you can say, “No; I have seen the place myself under ordinary working conditions,

and the job is quite suitable for him,” you enormously increase the value of your evidence. Again, I would have you remember that, though the medical aspect of the case is perfectly plain to you, it is seldom plain to the tribunal; so that you should give your evidence in a way which will commend itself and be intelligible to the court: give in as simple language as you can the data upon which you rely and the reasons for your conclusions—for example, “When I find this and this followed by that, I am certain the cause is so-and-so.” The judge says to himself, “This fellow knows his job, and I can see his line of reasoning—it strikes me as sound.” When you are being cross-examined keep your temper, for the gentle art of cross-examination embraces infinite styles and varieties, and some, I am sure, must be enough to try the temper of a saint. Listen carefully to the question; beware of double questions, and if you do not understand what is put to you, say so and get it made intelligible to you before you answer. When being cross-examined do not merely answer Yes or No to medical questions; such questions are put to you presumably—at least they should be—because the witnesses for the other side are going to give them as their views, so explain your reasons for not accepting what was put to you. Avoid arguing with the cross-examiner; if there is anything you consider really objectionable in a question or in the way of putting it appeal to the judge—you are entitled to be protected from unfair treatment—but, of course, don’t do that unless it is really bad. If an extract from a book is cited to you in cross-examination, remember that you are fully entitled to see the passage and its context before you give your answer; it not infrequently happens that when investigated with its context the point which was intended to be made against you wholly collapses; or the quotation may be from a standard work now out of date; or from an old edition of a work, in the recent edition of which a different view is given; or it may happen (indeed, has) that the passage was one cited by the writer of the book for the purpose of contradicting it or exposing its fallacy. But when you know that you are giving a view which is really contrary to the usually accepted view, be ready to fortify it by your special experience or other good ground.

Some doctors, I believe, are so rash as to have themselves committed their views to writing. If faced with some earlier observation of your own on a point on which you have really altered your view, do not try to camouflage the two views, but say why you have changed your mind in the light of further experience or whatever the cause was. I think myself that when such a situation is dealt with fairly by the witness in that way the effect on the judge’s mind is to confirm rather than detract from the value of his evidence. The judge knows as well as you do that science is never final—experience, new discoveries, increased research cause the modification or reversal of views previously held; and while the judge respects a man who is strong enough to say that he has changed his mind in the light of further experience, he necessarily views with mistrust the man who tries to explain away or reconcile the two opinions. When, as sometimes happens, you are going to give your opinion in the witness-box that a man was a malingerer, you must be prepared for awkward questions in cross-examination and be armed at all points. Of course, you sometimes are provided with fairly conclusive evidence—for instance, a man has had an accident some time ago and injured some muscles of his back. He alleges that it is still stiff and that he cannot stoop without great pain. You get him to describe his woes, and listen most sympathetically to all he has to say, and soon get an inkling how far he is to be believed. Then during a friendly chat you “accidentally” drop the handkerchief with which you are wiping your glasses, and of course, if he politely bends down and picks it up without a groan you probably will not need to stay much longer; but it is seldom, I suppose, that you get such easy positive proof.

Let me give you an instance of an actual experience in this connexion. Counsel was cross-examining to try and prove that a man really was suffering from neurasthenia, and that he exhibited certain symptoms of it. The doctor says, “No, he is malingering neurasthenia.” Counsel:

"Do you say that those symptoms can be voluntarily assumed?" Doctor: "Yes, I do." Counsel then asked him to give a demonstration of voluntary sweating. This so disconcerted him that he at once broke out into obvious perspiration, and so appeared effectively to establish his assertion, though one wonders whether it was quite a case of voluntarily sweating on his part.

If, as I suppose must sometimes be the case even with doctors, in cross-examination you find yourself being cross-examined on a subject on which you have no particular knowledge, do not try to answer; say you cannot deal with that; or, if you like, say what I heard said in court by a well known surgeon, indicating a well known physician who was going to give evidence also: "You'd better put that question to the finished article that follows me; I'm only a surgeon." I assure you the court will esteem you the more highly for not pretending to have knowledge that you do not possess. I need hardly advise you to avoid making any sort of attack upon the other medical witnesses or giving the impression that you consider yourself far superior. You probably know what Max O'Rell says of American experts—"Every fellow wishes the other fellow to think himself a devil of a fellow."

It is often a matter of amazement to counsel, and must even sometimes be so to yourselves, to find how completely doctors differ, or appear to differ, from each other in the evidence that they give about a case. Presumably both sides cannot be right—though I believe that in the great majority of such cases both sides are honestly giving their opinion; the reasons for this difference are no doubt various. Perhaps the most influential one is that of unconscious partisanship. You have become identified, as it were, with the one party: you are for his side; you cannot help noticing particularly and perhaps magnifying the points that assist your side's case; you overlook or fail to give due weight to points that do not fit in so well. The ideal medical witness should be on guard against this from the beginning; he should remember that he has probably approached the case at the very start with one side's views and wishes placed before him, and not the other's; he begins by looking for something, expecting to find it, instead of looking—with a quite open mind—to see what he does find.

Or, again, he is in the witness-box, is being cross-examined; he feels that it is "up to" him to justify the confidence placed in him by his side; it is human nature to want to "play up" accordingly, and almost unconsciously he adds a little or omits a little; he cannot bear the idea of "letting down" his side, or being what might seem to them "disloyal"; and when faced with a point which he sees might be unfavourable, he screws himself up just a little bit to enable him to discount it, justifying it to himself perhaps by saying, "Well, I know my man really is in the right, and is entitled to succeed." A clever cross-examiner will comprehend your state of mind, and try to get you to go a little further, and still a little further, and in the end you have to go too far and the damage is done.

Sometimes the cause for this difference of views is of quite another kind: there may be a real division in the profession upon the point under discussion—some think this, some that. Here is a chance for you to help counsel. As a rule doctors know something of each other's views and theories. I remember once in a case of nystagmus there occurred a remarkable difference of evidence. The question was, Had the man nystagmus or had he not? Eminent witnesses on my side said he had; an equally eminent witness on the other said he had not. Happily the mystery was solved: on a tip from my side the latter was asked what he meant by hating nystagmus, and he answered that he admitted no nystagmus where the symptom of oscillation of the eyeballs was not present—little he cared for the extended definition of that disease in the Workmen's Compensation Act. Again, it may be in some cases that the respective doctors may have made their examination at widely different times, and the patient's condition may have essentially differed; no doubt various other reasons will suggest themselves to your minds. I mention these matters to impress upon you that you can frequently be of great assistance to counsel, not only by your giving evidence in the witness-box, but by

closely following the whole evidence and giving advice to him on points of this kind which may be invaluable for cross-examination. May I add, when possible, jot down your "tips" on paper and let him have them; it is not at all easy to take them in from a whispered conversation, while perhaps counsel is on his feet examining or cross-examining. You must remember that rarely, if ever, has counsel sufficient medical knowledge of his own to hope to cross-examine a medical expert effectively; and rarely, too, I am glad to say, has he any ground for cross-examining such a witness as to honesty or credibility; and so his only chance of making any impression is by being supplied by you with material whereby he may throw some new light on the case, or lay bare the reason why the doctor under examination may have been misled into forming such an erroneous view of the case.

If you make a deduction from certain stated facts, be quite sure there is no flaw in your deduction. No less a person than a very learned judge whose face was an exact counterpart of that of George III on the coins, on one occasion when counsel was inviting a jury to infer a certain consequence from the likeness of two people to each other, interrupted him, saying, "Don't dwell too long on that. It has been said I am the son of His late Majesty George III because of my likeness to him; all I can say upon that subject is this: George III was never in Scotland, and my mother was never out of it; so if you can make me out to be his son, do. Now go on." Counsel, in a stage whisper, for the jury to hear, to his neighbour: "But they might have met at the border!"

When you are being cross-examined be on the look-out for questions which assume that you have said something which you have not said, or that something has been proved which has not been proved, and for questions to which you cannot properly answer Yes or No—for example, "Have you given up beating your wife?" Considerable latitude is allowed to the cross-examiner, but he has no right to put unfair questions or make inaccurate statements, and the witness is fully entitled to point out the inaccuracy, and, as I have said—in extreme cases—to appeal to the judge if he thinks the question unfair. When you feel that you have scored a point and floored the cross-examiner with your answer, be content—do not try to kick him as well. That proceeding is apt sometimes to do harm. Your parting kick perhaps discloses something that provides him with a new weapon. So let well alone; remember the epitaph on the tombstone of one who failed to do so: "I was well, I wanted to feel better; I took physic, and here I am."

Bear in mind always that your function is to assist the court to arrive at what you believe to be a correct conclusion upon the medical question in the case, and you will do that most effectively by not showing any resentment at cross-examination, or trying to score off counsel personally, but by answering the questions courteously and simply; and, as opportunity arises, giving the reason why you cannot accept this or that suggestion that is put to you. So long as the medical witness conducts himself as an impartial expert giving assistance to the court, no counsel will gain any advantage by attacking him; it is only where he shows himself biased, or gives the impression that he is keeping something back, that he really exposes himself to effective cross-examination.

A medical witness in the box generally gives his evidence in chief with greater effect if he is allowed to give it in his own way; it is enough as a rule for counsel to say, "You examined Mr. — on such a day; what did you find?" Then you state all that you regard as of importance, and he then asks for your conclusions. This is far preferable to the half-and-half sort of way that so often occurs where counsel asks about this and that, and then the doctor is left wondering whether or not to mention other matters that have not been specifically asked. When that position does occur I advise the doctor to go on and complete all that he thinks bears on the point; but such misunderstandings seldom arise when they have met previously at conference. Again, when you are giving your evidence for the defendants—that is, after the doctors for the plaintiff have been in the witness-box—you should be prepared for

your counsel to travel somewhat freely beyond your mere proof or report, because he will almost certainly ask you to give to the court your views upon the points made by the doctors on the other side; he will probably say, "Now, doctor, you heard Mr. B. say he thought this was a case of so-and-so; what do you say about that?" Then is your opportunity to explain why you differ, and to endeavour to do so in a way that will convince the court that your reasons are sound. By doing this you have incidentally made it difficult for the counsel who has to cross-examine you, because you have dealt in advance with most of his material; and if he still persists in putting it the judge gets a bit restive and says to him, "The doctor has already explained that; what's the good of merely putting it to him over again?"

I would like, if time permits, to say a word about the position of doctors as regards what is somewhat vaguely described as "privilege," in so far as it concerns cases that come into the courts. For a witness in court there is no privilege recognized by the law as regards facts which the doctor may have observed or with which he has become acquainted in his capacity as medical attendant. Obviously there cannot be, because it would conflict often with statute law and nearly always with the administration of justice. As to the former, I may instance the Notification of Diseases Act and the Notification of Births Act. As to civil and criminal proceedings, it is apparent that over and over again the ends of justice would be defeated if doctors were allowed to decline, when in the box, to give evidence of the facts which had become known to them.

One can easily understand that in many cases it must be very unpleasant for a doctor to find himself asked to disclose information about his patients; but I fear that he can do no more than appeal to the judge to know whether he is bound to answer. The judge will say Yes; but the doctor will feel that he has done what he can to preserve the confidential relationship between himself and his patient. If he persisted in refusing to answer he would be liable to be committed for contempt of court. Incidentally I may mention that what a witness says in the witness-box is privileged, which means that it cannot be made the subject of an action for slander.

Now may I just try to give you a short summary of my suggestions?

Approach the case with an open mind.

Your examination should be complete—not limited (except in obvious cases) to the part affected or injured, but generally, of the systems and organs; it may later prove to be as important to say that such and such symptoms were absent as that some others were present.

Investigate carefully all the objective symptoms, and if the man complains of some that you do not then see—for example, sickness or passing blood—try to get a chance of seeing them; satisfy yourself as best you can about the subjective ones; make and keep careful records, and date them; and make as sure as you can that you have got the facts right.

When you make your report or give your proof, let it be as intelligible as circumstances permit to the counsel who is to have it: give the dates of your examinations, what you observed on the several occasions (if more than one), and then your conclusions and the reasons for them; ascertain what are the issues or points in the case, and show the bearing of the medical evidence upon them; attend if possible at a conference with counsel, and tell him what are the debatable features, and the probable criticisms or attacks to be expected from the other side.

When the case comes on, be there, stay there, and listen to the opening and the evidence, and jot down for counsel any tips or comments that occur to you. Diagnose the judge, and see what treatment he needs; then give it to him when in the witness-box—for example, clear his mind of some fallacy you have seen him absorb.

When in the witness-box speak plainly and not too fast, and as much as you can towards the judge; it is a good thing as a rule to adjust your pace to the judge's note; watch his pen; keep cool; do not let counsel make you lose your temper; do not argue with him; do not answer questions without being sure you understand them; and

always remember that the judge regards you as there to assist the court in arriving at the true view, and to give your opinions and make your criticisms honestly and impartially. Try to convey to the judge a clear and definite impression of what your decision would be; he wants you to enable him to arrive at a right and a real conclusion, and not to feel that he ought to give a verdict such as a jury once gave where the doctor at an inquest flitted aside with lightning and foul play as being the cause of death, and the bewildered jury's verdict was "Death from a visitation of God under suspicious circumstances."

## An Address

ON

## CERTAIN PHASES OF LEUCOCYTE ACTIVITY.

DELIVERED TO THE SHEFFIELD MEDICO-CHIRURGICAL SOCIETY

BY

C. J. BOND, C.M.G., F.R.C.S.,  
LEICESTER.

### SECTION I.—PATHOLOGICAL.

In an article published in the *BRITISH MEDICAL JOURNAL* (January 11th, 1919) it was shown that when washed red cells are ground up, a drop of the suspension of the washed and sedimented debris, when incubated (in a closed cell) with two or three drops of the freshly drawn blood from the same individual, exercises a leucotoxic effect on the native leucocytes varying in intensity according to the degree of concentration of the red cell debris in the incubated blood. The leucocytes emigrate very sparsely from the incubated clot, and those cells which adhere to the slide show marked signs of arrested activity, and cytolysis.

### Malaria and Leucocyte Activity.

In *The Leucocyte in Health and Disease* (London, 1904) a description is given of the leucocyte films from the incubated blood of a malaria patient taken during the pyrexial and the apyrexial stages of the disease respectively.

In blood obtained during the rigor or pyrexial stage emigration is very scanty, and the cells are spheroidal and show the cytolytic changes characteristic of poisoned cells. If, however, the same clot be detached from the slide, washed in normal saline, and reincubated on a fresh slide, a much more copious emigration of active cells takes place from the same clot after the removal of the serum. This proves that the scanty emigration in the first instance is not wholly dependent on a reduction in numbers of the white cells.

The findings of different observers as to a rise or fall in the mononuclear and polymorph cell count in various phases of malaria, and in blood drawn from different parts of the body, vary a good deal. The fact, however, that the emigration is very scanty from the incubated blood clot, taken during the pyrexial stage, while it is active from the same clot after the serum is washed away, strongly suggests that the inhibitory influence is in some way due to the presence of the blood serum and not to any lack of leucocytes. If blood be taken from the same patient during the apyrexial stage, normal emigration occurs from the incubated clot.

### Induced Malaria.

The induction of malaria by the injection of blood from an infected patient in cases of general paralysis, for therapeutic purposes, has enabled us to carry out observations on malarial patients on a more definite plan.

The emigration picture is first obtained by incubating the blood from a case of general paralysis immediately before the treatment is commenced. A second emigration picture is taken during one or more of the dozen or so rigors which usually follow the injection of the infected blood. A third emigration picture is taken during the stage of treatment by quinine, and a fourth after recovery from the malarial infection. The character of the leucocyte

emigration in this induced form of the disease follows the same lines as in the natural disease—that is, inhibition of emigration during the pyrexial stage and normal activity during the apyrexial stage; and also after recovery by quinine treatment.

#### Paroxysmal Haemoglobinuria.

I have recently had an opportunity of studying the same problem in a case of paroxysmal haemoglobinuria in a child of 3, in whom, although the paroxysms were accompanied by malaise and the passage of a large amount of haemoglobin in the urine, no rigors and no marked rise of temperature occurred.

The emigration picture obtained from blood during the paroxysm showed only a few leucocytes, surrounded by threads of fibrin and red cells in various stages of degeneration. When the clot was washed in saline and reincubated a much larger crop of active cells was obtained. In the convalescent periods, during which the urine was free from haemoglobin, the emigration picture gradually returned to a more normal condition.

Eason<sup>1</sup> states that a slight leucocytosis is generally present during the paroxysm. If this be so, the failure of the leucocytes to emigrate from the clot cannot be due to a scarcity of these cells in the circulating blood. In order to test this point and to ascertain whether the blood serum during the paroxysm is leucotoxic, three drops of my own blood were incubated in a closed cell with one drop of the patient's blood serum diluted with normal saline. The effect on my own leucocytes, though slightly inhibitory, was not very marked. When, however, my washed red cells, previously treated for one hour with the same serum, diluted with normal saline, were incubated (after rewashing) with my own blood, a striking effect was produced. Only a very scanty emigration of damaged leucocytes occurred, and many of these cells had debris of red cells hanging to them. In a control film, in which the same washed red cells were used without previous treatment with the haemoglobinuric serum, a good emigration field of normal cells was obtained.

This observation shows that the serum of the haemoglobinuric patient exercises its effect on foreign as well as native red cells, at room temperature *in vitro*, and that when cells so treated are incubated (after rewashing) with foreign blood, the red cells apart from the serum acquire a leucotoxic character. This observation is in harmony with the hypothesis put forward by Eason, Landsteiner, and other observers, that the recurring attacks of haemoglobinuria are due to the presence in the blood of a substance (amboceptor) which at a low temperature attaches itself to the red cells. When the local or general temperature of the blood rises, this substance acts as an intermediary body, and links the complement normally present in the plasma to the red cells, and thus brings about haemolysis.

These facts, taken in conjunction with our previous observations on malarial blood, suggest that disintegrated red cells, when damaged, either by invasion by the malaria parasite or as the result of the action of some haemolytic substance, as in haemoglobinuria, do exercise a profound leucotoxic effect *in vitro*; and further, this leucotoxic substance, whatever it be, only apparently becomes leucotoxic after it has been linked up with the red cells of the patient.

In diseases like malaria and haemoglobinuria, in which a mass destruction of red cells occurs periodically, leucotoxic substances are present in the blood serum during the acute phases of the disease. The removal of the blood serum from the clot *in vitro*, and the restoration of the serum to normality during the recovery stages *in vivo*, removes the inhibitory influence, whatever it be, which prevents the emigration of the leucocytes, and which, if present in a more pronounced form, brings about the death of the emigrated cells.

#### Leucocytic Emigration in Pneumonia.

It will readily be recognized that the emigration picture in diseases which are characterized by a mass destruction of red cells will probably be very different from the emigration picture seen in other diseases, especially those of bacterial origin. In pneumonia, for instance, in the acute febrile stage, the carpet of leucocytes which covers the floor of the cell in which the blood is incubated is a

thick one, the cells are very active, and a large quantity of iodophil substance is liberated. At the same time the increased leucocytosis which is present in acute pneumonia must be borne in mind.

In this connexion some observations by Dr. Gardner-Medwin<sup>2</sup> suggest that a leucopenia is actually present in the general blood stream during the early days of an attack of acute pneumonia, but that this is succeeded by a leucocytosis at a later stage. However this may be, the emigration picture from incubated blood in pneumonia in the acute stage is a striking one, and is in marked contrast to that seen in malarial and in paroxysmal haemoglobinuria. It may be that in paroxysmal haemoglobinuria a more extreme form exists of a condition ordinarily present in many other diseases (as in pneumonia), where red cells are agglutinated to, and undergo ingestion by, leucocytes in considerable numbers. These conditions can be so modified experimentally by removing the blood serum from the clot that the emigrating leucocytes can be induced to agglutinate and ingest washed native red cells on a wholesale scale.

#### Leucocytic "Aggressiveness."

If the red clot from which the first crop of leucocytes has been obtained be washed in normal saline to remove the blood serum, and reincubated on a fresh slide with a drop of a suspension of the washed red cells from the blood of the same pneumonia patient, the same phagocytic activity—that is, the aggressiveness—of the same leucocytes to their own washed and native red cells will be much more marked. Almost every leucocyte will be surrounded by a number of adherent red cells, and many will contain one or more ingested erythrocytes. This heightened "aggressiveness" to red cells on the part of leucocytes in the washed clot is not wholly specific in character—that is, it is not limited to native red cells; it extends to the red cells of other individuals, and to non-human red cells. Thus, washed red cells from certain individual sheep, which are sufficiently toxic to inhibit emigration and poison the leucocytes when incubated with human blood, will be readily ingested by the same leucocytes after the removal of the serum from the washed clot when reincubated on a fresh slide.

Moreover, this altered relationship between red cells and leucocytes in a disease like pneumonia may be brought about in normal blood (*in vitro*) by treating the washed red cells of one individual with the blood serum of another individual, or with the blood serum of the sheep, under certain conditions. After rewashing the clot red cells so treated may be readily agglutinated to and ingested by human leucocytes, whereas previously they produced no reaction on the part of these cells, or were so leucotoxic as to prevent emigration.

These and other facts suggest that it is some change on the surface of the red cell which brings about the altered attitude on the part of the leucocytes. We shall consider later whether, in addition to the deposition of this additive substance, some other substance may also not be removed, and whether by this process of addition and subtraction a profound chemical change may not be brought about in or on the surface of the red cell.

#### The Spleen and Leucocytic Stimulation.

We may regard the lacunar spaces in the spleen and the backwaters in the circulation as regions in which this aggressive action of the leucocytes on the red cells reaches a high level. Thus, in a case of enlarged spleen, in a man (also the subject of syphilis, with a history of previous malaria) in whom the spleen was removed by operation, serum from blood drawn from the finger—that is, the general circulation—when incubated with my own leucocytes and examined under dark-ground illumination, gave an emigration picture in which the individual leucocytes showed only moderate activity, while serum from blood taken from the splenic vein at the time of operation and incubated in the same way had a much more marked stimulatory effect, and greatly increased the pseudopodial activity of my leucocytes.

This comparative observation on serum from the general and the splenic circulation confirms the previous statement that substances which are capable of stimulating the

aggressive activity of leucocytes towards red cells are present in the blood in situations and in organs where, normally, red cells are undergoing disintegration.

In an interesting article on the spleen<sup>3</sup> Barcroft has described that organ as a reservoir from which large numbers of red cells are thrown into the circulation under certain conditions. The observations just recorded seem to suggest that substances having a leuco-stimulating character are present in the blood after it has traversed the splenic tissues. It may probably be that, as with bacteria so with red cells, a previous opsonization of the red cells by the blood serum is necessary to enable the leucocytes to ingest them.

It seems clear, however, that it is possible to reduce the leucotoxicity of a given sample of washed red cells *in vitro*, not only by treatment with an appropriate serum, but also by treatment with certain chemical substances.<sup>4</sup> Further, it is possible to increase the "aggressiveness" of the leucocytes to both native and foreign red cells *in vitro*, just as occurs irregularly in vaccine therapy, and with more uniformity through the influence of a previous infection, as in those diseases in which one attack confers subsequent immunity.

#### SECTION II.—PHYSIOLOGICAL.

The observations now to be recorded are concerned with the chemical and physical changes which can be observed in leucocytes as the result of, or in association with, the so-called process of stimulation.

One of the earliest signs of commencing activity shown by the white blood cells when removed from the circulation and incubated outside the body is a vibratory movement of the cell granules. This "boiling appearance" is seen in all varieties of leucocytes, but more in some kinds than in others. It may continue under favourable conditions for some hours, and as the liquefaction of the cell substance commences the amplitude of the granular movement increases. At a later stage it slows down, and finally ceases.

If a leucocyte film be prepared from incubated blood in a closed glass cell, the active cells which form a carpet on the floor of the cell do not, for the most part, stain with a 1/2 per cent. solution of ruthenium chloride in normal saline; or, as this reagent is called, ruthenium red. A few odd leucocytes may show nuclear lobes of a rosy pink colour, but the great majority of the cell nuclei remain unstained. If the film is treated, however, with a 1 per cent. solution of iodine in normal saline, and is then washed in the saline, the majority of the cell nuclei will quickly stain with the ruthenium red. It is possible to bring about the same result by incubating the film in normal saline through which air is frequently bubbled, but the oxidation process takes one and a half to two hours before the cells will react to the stain.

If the film be treated with a weaker solution of iodine (1/2 per cent. in normal saline) for a few seconds only (four to twelve), and the iodine be then quickly washed away, and the film (covered with normal saline) be placed in the incubator for a few minutes, many of the cells will be seen on examination to be exuding colourless droplets. Some of these globules remain attached to the cell for a time, and then gradually dissolve in the surrounding medium. These droplets are composed of substances some of which have a strong avidity for iodine, and stain with it a pinkish-mauve, or, when more concentrated, a port-wine colour. If to the film so treated with a wash of weak iodine the solution of ruthenium red be added, many of the cells still remain unstained. For the most part it is the cells to which these iodophil droplets are attached which do not stain with the ruthenium red. The cells which show the pink-coloured nuclei have probably passed through the first stage of partial oxidation, and have reached the later stage in which the nucleus has become exposed by the removal of the lecithin coat, and under these conditions the nuclear substance combines with the ruthenium red.

Examination of the film at this stage under dark-ground illumination confirms this view. Thus, the iodophil globules can be seen exuding from, or in some cases distending, the cell. The nuclear lobes in these liquefying cells often appear more translucent, as though more liquid

than in cells in which these droplets are absent. The nuclear material can often be seen streaming along one or more of the pseudopodial processes. If a second dose of a stronger solution of iodine (1 per cent.) be floated under the covered glass, the droplets take on the mauve colour, and when the excess of iodine is washed away and the ruthenium red again added all the cell nuclei show the pink stain. What is the significance of this fact—that the cell nuclei do not stain until they have been acted on by the second dose of iodine? We know that the semi-permeable membrane, or the perinuclear meshwork which normally surrounds the nucleus, is composed of a lipid material (chiefly lecithin) in combination with magnesium or calcium, the lecithin component being in a comparatively insoluble form. The first effect of the oxidizing agent, the iodine, is to bring about a change in this lecithin coat. The membrane becomes more soluble and is partly removed, and the nuclear substance is thus exposed to influences which reach the cell from outside. The cell now begins to form iodophil substances in the form of droplets. These droplets consist partly of lecithin in the water-soluble form with traces of cholin split off from the oxidized lecithin, and it is probably this cholin component (and not glycogen as was previously thought) which gives the droplet its capacity to stain mauve with iodine.

This exudation of substances from the cell which have the capacity of lowering the surface tension at the contact face between the cell and the medium brings about the protrusion of dendritic and pseudopodial processes, and eventually results in the cell movements. It also contributes to the surrounding and engulfing of red cells, micro-organisms, and other foreign bodies by the leucocytes. It constitutes, in fact, an essential factor in phagocytosis.

#### Experimental Evidence.

I must now give some experimental proof that this view of what happens in the cell when activity commences is founded on sound evidence. It is first necessary to establish the fact that the capacity of the nucleus to stain with ruthenium red depends on a denudation of its lecithin coat and consequent exposure of the nuclear material to a water-soluble substance like ruthenium red. The following observations bear on this point.

A leucocyte film, obtained by incubating normal blood in a closed cell, is treated with a faintly acid 1/2 per cent. solution in normal saline of potassium chloro-platinate for one hour. The excess of the platinum salt is then washed away in normal saline and a 0.05 per cent. solution of benzidine base in distilled water is added to the film. A blue-coloured deposit is formed, which reveals the situations in the cell where the platinum salt has combined with the lecithin compound to form a precipitate.

Two points, however, at once arise. First, how do we know that the blue deposit seen in the cell is really a lecithin-platinum precipitate coloured blue by the benzidine, and not some protein or other constituent of the cell? In the first place, the potassium chloro-platinate in neutral solution does not give a precipitate with the globulins or plasma proteins, while it does combine with water-soluble lecithin to produce an insoluble lecithin chloro-platinate in the presence of weak acids. Also reagents like mercuric perchloride and iodine, which precipitate serum albumin, do not precipitate lecithin. As long as the lecithin is present in the cell in the form of the magnesium or calcium compound it does not react with the neutral platinum salt. This can be demonstrated in the test tube by taking some lecithin magnesium sediment, suspended in water, and adding the neutral platinum salt in solution to it. No reaction occurs, and no blue deposit when benzidine is added after washing the precipitate. If, however, the lecithin magnesium compound be first converted into the water-soluble lecithin by treatment with sodium chloride, then the soap-like solution so formed precipitates with the chloro-platinate, and, after removing the excess of the platinum salt, this precipitate is coloured blue on the addition of benzidine. The demonstration of the arrangement and location of the lecithin substance in the cell by means of precipitation as a chloro-platinate is of considerable physiological interest, because it serves as an indicator of successive stages of cellular activity.

In the inactive phase, as in the white blood cells circulating in the blood, little or no blue deposit is seen after treating the washed leucocytes by the chloro-platinated benzidine method, although a few blue granules may appear on the surface of the cells. In the slightly stimulated condition, as in cells which have emigrated from the clot when blood is incubated, the lecithin material becomes water-soluble through partial oxidation. Under these conditions a blue deposit is seen as a granular membrane covering the nuclear lobes when the film is treated with platinum and benzidine.

In cells which have undergone further stimulation and have reached a further stage of activity (as by a wash of weak iodine, or by incubation in a medium, which stimulates dendritic formation and iodophil droplets) the blue material is scattered through the cytoplasm as blue grains or masses, and it may collect as a blue ring at the margin of the cell. Further, since the water-soluble lecithin tends to flow out of the cell in the form of iodophil droplets, it is possible to prevent this material from dissolving in the surrounding medium by treatment with a weak solution of mercury perchloride. In such cases, after treatment with platinum and benzidine, the blue deposit often forms a film over the surface of the exuded droplets.

Treatment of the leucocyte film with a 1 per cent. solution in normal saline of phospho-tungstic acid produces some change or precipitation in the substance forming the iodophil droplets, whereby the droplet stains with basic dyes such as Nilo blue after the phospho-tungstic acid has been previously removed by washing. Experiments have been carried out with other substances which exert a solvent action on the lecithin nuclear membrane without unduly damaging the cell. Thus, cyclohexanol dissolves the insoluble magnesium lecithin compound in a test tube.

If a leucocyte film be washed with a 3/4 per cent. solution of cyclo-hexanol (hexhydrophenol) in normal saline, the nuclei in the great majority of the cells at once stain pink with ruthenium red. This reagent, by removing the lecithin coat, exposes the nucleus to the ruthenium salt. A saturated solution of ethyl ether in normal saline, on the other hand, while it dissolves the water-soluble sodium lecithin compound, leaves the insoluble magnesium form untouched; other also brings about a curious fusiform swelling of the protruded dendrites in the incubated leucocyte film which may be due to surface tension changes which follow the solution of the lecithin, and thus to the retraction of these processes.

#### Pus Cells.

Pus cells can be used instead of incubated white blood corpuscles. If the liquor puris be removed from healthy pus by washing and centrifuging in saline, the cells so treated can be divided into two groups by the addition of ruthenium red: (a) living cells, which remain unstained; and (b) devitalized or exhausted cells, in which the nuclei take on a pink colour.

On warming the slide the unstained cells commence to throw out dendrites and pseudopods, and eventually form iodophil droplets, while the cells with the stained nuclei retain the spheroidal form of the inactive or the dead cell. Further, if a drop of such living pus in normal saline be incubated for a short time, and then treated by the chloro-platinated benzidine method, an association can be traced between the distribution of the lecithin compound and the vitality and activity of the cell. The blue deposit appears as a ring surrounding the nuclear lobes in the less active, and as blue masses scattered through the cytoplasm in the more active cells, while in the dead cells, in which the nuclei stain deeply with ruthenium red, the lecithin material is absent, having been washed out of the cell; and no blue deposit is obtained. In the inactive, resting white blood cell, on the other hand, the lecithin substance, although present, is in the insoluble form, and consequently no blue deposit is formed with benzidine. The same result has been obtained with the neutral chloro-platinated, and subsequently fluid from a case of pneumococcal meningitis. About one-third of the leucocytes stained pink with ruthenium red, the rest remained unstained. Another portion of the same

deposit was treated by the chloro-platinated and benzidine method. The cells showed very little blue deposit. When the same sedimented fluid was incubated, however, an entirely different picture was obtained. Each film of three portions of the sediment were taken and incubated for three-quarters of an hour, for half an hour, and for a quarter of an hour respectively. Each film of the chloro-platinated and benzidine method. The first film showed a fair emigration carpet of active cells, with some blue material, mostly in the neighbourhood of the nucleus. The second film showed more blue deposit, scattered through the cell. The third film presented the same picture in a more advanced form, and, in addition, blue material was seen in the surrounding medium, starting from points which were probably particles of the lecithin compound which had exuded into the medium.

Just as the capacity to stain with ruthenium red depends on exposure of the nucleus, so the capacity of the lecithin membrane to react with the chloro-platinated benzidine stain by testing the water-solubility of the lecithin compound. Thus by testing the capacity of the nuclear substance to stain with ruthenium red, and by testing the distribution of the lecithin compound in the cell by the chloro-platinated benzidine method, some idea can be formed of the stage of activity of the cell. The rapidity and the completeness with which the nucleus stains with ruthenium red provides a means by which the proportion of living to dead cells can be quickly ascertained in any given sample of pus, and affords a useful criterion of the healthiness of a wound apart from any examination of the number of organisms present, provided the cell has not been exposed to oxidizing reagents which would tend to denude the nucleus.

#### Oxidation and Contact with Foreign Substances as Factors in Cell Activity.

Before leaving the subject of oxidation some reference must be made to previous observations on this point. Metchnikoff, in his classical researches, dealt with the role played by oxidation in stimulating leucocytic activity. More recently Sir A. Wright<sup>1</sup> has recorded observations on the bactericidal property of blood obtained under anaerobic conditions. I have recently reinvestigated this question from the point of view of leucocytic activity. If a little saucer-like shelf be made by coating a circle of wire with hard paraffin, melting above 37° C., this little shelf can be let down into a beaker of liquid paraffin, and a drop of blood drawn from the paraffin-coated finger can be placed on the shelf without coming in contact with the air or any foreign substance other than the liquid paraffin. The drop of blood remains for a considerable time as a sphere, standing upon and only touching the paraffin shelf at one point of its convex surface. Coagulation is then placed in and a droplet of serum exudes from and adheres to the coagulated sphere.

During incubation, and before coagulation takes place, or at any later period if defibrinated blood be used, the still liquid blood can be drawn up in a very fine pipette, and blown out and examined on a slide. The leucocytes, although they have been incubated for a considerable time, will appear as spherical, inactive cells, resembling white blood corpuscles, floating freely among the red cells. If, before submergence in the liquid paraffin, the drop of blood be received through the air into a drop of normal saline containing a little dissolved glutathione\* or other substance which acts as an oxygen carrier, and then placed on the paraffin shelf and incubated as before, the leucocytes on examination will have lost the perfectly regular outline, and will be roughened by projections from the surface, resembling immature dendrites. If treated with iodine some of the cells appear of a port-wine colour. Chemical changes have commenced in the cell which, if carried further, would lead to the production of iodophil droplets and dendrites.

\* I am much indebted to Professor Sir Gowland Hopkins for the glutathione. This substance, when added to the blood plasma, greatly stimulates leucocytic activity and pseudopodial movement in the incubated blood.

The reason why these do not form, although the cells have access to oxygen, is, I think, owing to the absence of contact with foreign surfaces. No localized reduction of surface tension is produced at any one portion of the surface of the cell. Hence the cells preserve roughly the circular outline. They show, however, a slight tendency to stick together, and to form agglutinated groups of white cells, although they do not adhere to the red cells. These and other observations enable us to say that in the entire absence of oxygen leucocytic activity is delayed, even at a temperature of 37° C.

But although oxidation may set going the chemical changes in the cell which lead to the formation of iodophil dioplets and other effects, contact with foreign substances is necessary to bring about those localized surface tension changes on which dendrite formation and pseudopodial movement depend. These and other observations point to the fact that, when incubated under conditions which prevent contact with foreign substances, certain chemical changes are initiated, but that contact is necessary to bring about phagocytosis in the full sense of that word.

This is shown in another way. If a slip of glass, previously heated in a flame to drive off the air, be inserted into the blood drop in which the leucocytes are undergoing incubation under the liquid paraffin, the leucocytes at once attach themselves to the glass surface and throw out dendrites and pseudopods.

#### *The Reversible Process in Leucocytic Activity: Cell Recovery.*

Although it has not been possible with our present crude methods to demonstrate fully the recurrence of anabolism following katabolism in a very delicate cell like the leucocyte, after cellular activity has reached the stage at which the nuclear membrane undergoes solution, and the nuclear substance stains deeply with ruthenium red, and iodophil substances have been elaborated and dendrite formation has occurred, yet it can be shown that recovery does follow on a less advanced phase of activity.

For instance, living pus cells (which are simply leucocytes which have emigrated from the blood vessels) must at an earlier stage have been sufficiently active and sufficiently mobile, both as regards their nuclear and cytoplasmic substances, to enable them to pass between the endothelial cells lining the capillary wall. When we recover these pus cells, however, from a well drained pleural effusion, or from the surface of a healthy wound, they have returned to the spheroidal shape and inactive condition, although they are by no means dead cells. When washed in normal saline and incubated they rapidly resume activity; they throw out dendrites and pseudopods, and they elaborate iodophil material, and, if activity proceeds further the lecitin membrane may undergo solution, and the nucleus become exposed, and it can then be stained with ruthenium red.

I have already said that in a film of emigrated leucocytes from normal blood a few odd cells will stain with ruthenium red. Are these cells which stain at once dead cells? Are they cells which have wandered on to the surface of mucous membranes, or into the tissue spaces, and have returned by way of the blood stream or the lymph stream to the general circulation by a process of what I have termed "return immigration"? If so they should be found in large numbers in the blood of persons in whom inflammatory foci, or wounds, or catarrhal conditions of the mucous membranes are present.

On the other hand, they may be cells which have become injured in the process of drawing the blood. There are some suggestive facts which bear on this point. In the incubated blood from a patient recovering from pneumonia with a normal temperature, but with some unresolved consolidation at the base of one lung, the leucocyte film of emigrated cells so obtained showed but few cells giving the pink colour. The clot was then detached from the slide, washed, and reincubated on a fresh slide. In this second crop a large number of cells showed pink-coloured nuclei when treated with the same reagent. The second crop of cells from the washed and reincubated clot from the blood of a healthy person remained unstained when treated in the same way. This suggests that the leucocytes in a patient recovering

from pneumonia, even after a week of normal temperature, are in a more unstable condition or are less rich in lecithin than in health—that is to say, their lecithin nuclear membrane is more permeable.

The following observations also throw some light on "cell recovery." A cell containing normal blood was incubated for half an hour, and then allowed to stand at room temperature for twenty-four hours. The emigrated cells, which, if examined immediately after incubation, would have been very active and adherent to the slide by dendritic processes, have now, after twenty-four hours, returned to the spheroidal shape. Some of them have become detached from the slide by the retraction or the rupture of their dendrites, and float freely in the serum as circular cells. The cells still adherent to the glass are nearly all more or less circular in outline; in some of the cells the nuclei stain with ruthenium red, while in others they remain unstained.

If such a film of "recovered" circular cells be washed in normal saline and again reincubated for a quarter of an hour in a mixture of native blood plasma and normal saline, or preferably Marshall's solution, these spheroidal inactive cells quickly resume activity. They throw out dendrites, they adhere to the slide, and they elaborate iodophil material. Moreover, they can again revert to the circular form and again be induced to resume activity a second time by repeated incubation. This observation shows that cells in this inactive phase are not necessarily dead cells. If, as I think, they are cells which, after passing through a katabolic or active phase, have reverted to the resting condition, an important fact will have been established in the life-history of the leucocyte and probably also in that of other cells.

In this matter of the development of acidity by cells when in the active phase it is of interest to note that Roux,<sup>1</sup> in 1913, showed that fragments of embryonic tissue explanted into plasma coloured blue with litmus turned pink (that is, developed acidity) as growth proceeded, but remained blue if growth was arrested. Peyton Reus has also recently shown<sup>2</sup> that acid substances are formed within leucocytes and other phagocytic cells under certain conditions during cell activity.

Levaditi and Gabrick<sup>3</sup> also showed that pieces of tissue stained with neutral red and explanted in plasma become colourless as growth proceeds, while sterile portions turn yellow—that is, remain alkaline.

I have previously shown<sup>4</sup> that the property of elaborating iodophil substances is not confined to leucocytes. It is present in certain epithelial cells, both in the skin and in mucous membranes, especially those lining the orifices of the mucous canals, also in some marrow cells, in the giant myeloid cells in sarcomata of bony tissues, and in some cancer cells of epithelial origin.

In the light of the observations now recorded it seems probable that this iodophil substance is not glycogen, as was originally thought, but (as shown by the reactions given with platinum salts) that it consists partly at least of lecithin in the water-soluble form, together with cholin split off from the lecithin. Further, it seems probable that the lecithin component is derived from the partial solution of the perinuclear lipid membrane during cell activity, and that cell recovery depends on the lecithin content of the cell, and may be associated with the restitution of this perinuclear lecithin membrane.

If these observations are confirmed, then I think a further step will become possible in the elucidation of the difficult problem of the chemical changes associated with katabolic processes in the life of the leucocyte, and probably also in many other cells.\*

## ESTIMATION OF THE CARDIAC OUTPUT AS A MEASURE OF ITS EFFICIENCY.

BY

T. STACEY WILSON, M.D. EDIN., F.R.C.P.,  
CONSULTING PHYSICIAN, BIRMINGHAM GENERAL HOSPITAL.

THE clinical estimation of the cardiac output depends mainly upon the fact that we are able to observe the extent to which the heart is able to distend the two largest elastic viscera of the body—namely, the lungs and the liver; for a variation in their degree of distension must, owing to their elasticity, result in a variation in their size and in the tenseness of their tissues. Owing to a difference in the density and in the anatomical relationships of these two organs, there is a difference in the clinical method whereby the degree of their distension with blood can be estimated.

### *The Size of the Lungs as a Measure of Cardiac Output.*

The great elasticity of the lungs ensures that a considerable variation in their size must accompany any serious variation in the volume of blood in their blood vessels. A lessened cardiac output due to cardiac inefficiency is followed by a recognizable diminution in their size, and, vice versa, an increased distension with blood (as in chronic venous congestion) is followed by a recognizable increase in their size. The accessibility of the lungs to physical examination renders it easy to note these changes, and in the absence of variations in circulation due to vasomotor control makes the information gained reliable as an indication of the cardiac output.

Owing to the relative rigidity of the thoracic walls any variation in the size of the lungs must result in an alteration in the average level of the diaphragm, and in the degree of hollowing of the suprascapular fossae. These variations in the level of the diaphragm are easily detected, when a patient is recumbent, by percussing out the upper border of the liver dullness on the right side and of the gastric resonance on the left side, for there is almost always enough air in the stomach to admit of the lower level of the cardiac dullness being defined by percussion when the patient is in this attitude. Clinical cases, with diagrams illustrating variations in the level of the diaphragm, are given in my book *The Early Diagnosis of Heart Failure* (pp. 168-178, also 182-183 and 195-199).

### *Degree of Distension of the Liver as a Measure of Cardiac Output.*

In the case of the liver the relative density of its tissue does not favour much variation in its size with variations in its distension with blood; but the configuration of its lower portions, together with their anatomical relationships with the subjacent air-containing viscera, do constitute a very delicate clinical guide to the degree of distension of the liver tissues.

To make this point clear it is necessary to remember the principles which underlie the practice of percussion of a solid body which overlies a resonant, air-containing viscus. If the solid body be elastic and distensible (such as the liver) percussion over it will elicit the resonant note of the subjacent viscus if its tissue be either tensely distended or if it be relaxed, for in either case it will transmit the vibrations of the percussion stroke just as any other hard solid or soft solid body would. When, however, it is sufficiently distended to possess a certain amount of definite elasticity it will be capable of absorbing the vibrations due to the percussion stroke, and thus preventing them from eliciting the resonance of the subjacent cavity; and therefore percussion over such an elastic solid will then give a dull note, if its thickness is sufficiently great in proportion to the force of the percussion stroke.

Now it is a fortunate fact clinically that the liver tissue, when normally distended with blood, does possess to its maximal extent that degree of elasticity which is necessary for the absorption of percussion vibrations, for, as we know well, in the case of a gentle percussion stroke liver tissue half an inch or less in thickness is capable of giving a dull note on percussion when overlying resonant viscera. A very

slight lessening of its distension, however, such as characterizes a slight degree of cardiac inefficiency, is sufficient to lessen this power and prevent the thinner portions of the liver from giving a dull note when overlying the stomach or intestines. This statement can easily be put to clinical proof. If a series of patients be examined who are suffering from the slightest degrees of cardiac inefficiency which cause the lassitude so commonly observed after influenza and similar infective conditions, it will be found that in the majority there is distinct curtailment of the area over which an absolutely dull liver note would be obtainable in a similar series of healthy persons.

In cases of really severe myocardial weakness the absolute liver dullness often does not reach the middle line of the costal arch, and in very severe cases may be unobtainable internal to the right of the nipple line.

As further proof of the accuracy of this method of gauging the cardiac output it will be found, on carefully mapping out the area of absolute liver dullness in such cases, that as soon as improvement sets in the area of absolute liver dullness enlarges day by day until it once more returns to the normal size.<sup>1</sup>

### *Diminution of the Cardiac Dullness an Evidence of Lessened Cardiac Output.*

Although the amount of recognizable cardiac dullness varies much in patients whose circulation appears to be normal, and although in emphysema it may be absent although the heart be actually enlarged, yet nevertheless a lessening of the cardiac dullness is a valuable sign of lessened cardiac output. This diminution in the area of cardiac dullness may be in part due to the diminution in the size of the heart which accompanies lessened output. Other factors may contribute to this diminution in the cardiac dullness—such as a badly filled aorta or pulmonary artery allowing the heart to fall away somewhat from the anterior chest wall.

A careful study of many cases showing loss of cardiac dullness, however, suggests the probability that the amount of cardiac dullness depends primarily upon the tenseness of the heart and its contained blood, just as is the case with the liver. This may seem theoretically to be altogether improbable, but the clinical evidence in favour of it is very strong. There are certainly clinical grounds for the assertion that valuable information as to the cardiac output can be obtained by observation of the area of the cardiac dullness, and from carefully noting the variations in its size from day to day.

### *Estimation of the Patient's Vigour as an Indication of the Vigour of the Circulation.*

The general practitioner who knows his patient well is able to form a very sound estimate of the cardiac output (when other causes of want of vigour can be excluded) by taking the common-sense view that the vigour of an individual must be proportioned to the effectiveness of the circulation. The same principle of judging the amount of blood the heart is able to circulate without embarrassment finds expression in the exercise tests now so generally adopted for ascertaining the efficiency of the heart. Both these tests, though valuable and reliable up to a certain point, are by their nature only applicable to the less severe degrees of cardiac inefficiency. They give us, moreover, no detailed information regarding the circulation.

### *Estimation of the Cardiac Output by the Study of the Pulse.*

Little information as to the cardiac output can be obtained from the radial pulse (except in the severe degrees of cardiac inefficiency) unless the normal pulse for the individual be well known to the observer. When, however, the normal pulse is well known the radial pulse can give useful information as to the falling output due to cardiac inefficiency.

There are, however, many fallacies which must be guarded against owing to the effect of vasomotor changes upon the peripheral circulation. For instance, in a patient with normally somewhat high blood pressure lessening in the fullness and force of the pulse may only mean that there had been successful elimination of the toxic materials

which were the cause of the high blood pressure; the feeble and more empty radial artery, instead of meaning lessened output, may be accompanied by greater efficiency of the circulation and an increase in the cardiac output.

In the brachial artery, when a sphygmomanometer is used really valuable information as to the cardiac output is obtainable if the range of oscillation of the needle of the aneroid be studied as well as the systolic and diastolic pressures. An abnormally small range of oscillation naturally implies a deficient distension of the arm with blood at each beat of the heart, and therefore presumably a lessened output. It is often possible by the use of the sphygmomanometer alone to diagnose cardiac inefficiency such as that which follows influenza, and to forecast with fair accuracy what other signs of deficient output will be observable in the patient. It must, however, be remembered that in certain conditions small oscillation of the pulse does not imply diminished cardiac output, but only an abnormal state of the peripheral circulation. For instance, a small range of oscillation usually characterizes Graves's disease, Ménière's vertigo, and allied conditions. Information as to the cardiac output can also be gained by noting the nature of the sound heard at the bend of the elbow when using the auscultatory method of reading the blood pressure. A distinctly slapping sound is suggestive of badly filled arteries, due either to failure in cardiac output or to undue relaxation of the arterial system.

When knowledge of the sphygmomanometer has been further increased it is possible that valuable information as to the cardiac output may be given by the relation of the systolic pressure estimated by the finger to that estimated by auscultation, taken in conjunction with the information given by the range of oscillation of the needle of the aneroid.

On comparing the information gained by observation of the size of the lungs, of the physical condition of the liver as judged by percussion, together with the size of the area of cardiac dullness and the results given by the sphygmomanometer, a very trustworthy and exact estimate can be formed as to cardiac output, and the recognition of myocardial weakness will be made more easy, whether toxic in nature or due to atheroma of the coronary arteries. It must, however, be borne in mind that the cardiac output may be lessened by the compensatory diminution in the total volume of blood in circulation which occurs (apart from cardiac weakness) in starvation and certain other pathological conditions.

## URINARY INFECTIONS WITH *B. COLI* AND THE PYOGENIC COCCI:

THEIR PATHOLOGY AND THEIR TREATMENT  
WITH COLLARGOL.

BY

HAROLD H. SANGUINETTI, M.D., B.Ch.,  
PATHOLOGIST, LONDON TEMPERANCE HOSPITAL.

A THOUSAND years ago Rhazes<sup>1</sup> described a case of urinary infection in a young man, but it was not until, at the fifteenth French Congress of Surgeons in 1892, Guyon and Reblaub<sup>2</sup> called attention to the frequent occurrence of spontaneous urinary infections—that is, infections not resulting from trauma or consequent on obstruction—that medical men became alive to their existence. Guyon then expressed the view that the infection was an ascending one from the bladder to the kidney, but ever since there has been a controversy about this question, concerning which there are now two main views.

The first view, the one enunciated by Guyon and vigorously supported by C. R. Box<sup>3</sup> among others in this country, maintains that the infection passes from the external surface of the urinary organs along the urethra to the bladder and thence upwards to the kidneys; while according to the second view the infection is haematogenous, and first affects the kidney and its pelvis, whence it passes down into the bladder. Frank Kidd is a firm upholder of

this view, which is accepted by Sir William Hale-White<sup>4</sup> and probably by the majority of physicians and surgeons. Of course, the fact of the infection being haematogenous would not preclude primary infection of the bladder with ascent to the kidney. The upholders of the ascending view lay stress on the far greater frequency of the complaint in females than in males, while their opponents point out that, although less frequent than in females, cases of urinary infection are quite common in males, in whom the length of the urethra renders the probability slight of an infection spreading from the meatus to the bladder, even if contamination with the most common infecting organism, the *B. coli*, were more frequent than it probably is. Experimental evidence of the effects of the presence or absence of obstruction is adduced in favour of their argument by both sides. Frank Kidd<sup>5</sup> maintains that "Pure cystitis seldom occurs, but when it does it is never associated with fever. This is because the bladder is designed as a reservoir, is poorly supplied with lymphatics that it shall not absorb water, and therefore equally not poisons."

Now the line of treatment adopted must depend on which of these views is correct. In the end we shall probably find that both views are correct—that is, that in some cases the infection starts in the bladder, in others in the kidney, and that naturally a different line of treatment will be needed for each class of infection. J. S. Dudgeon<sup>6</sup> and his co-workers showed that in 74 per cent. of *B. coli* infections in females a non-haemolytic bacillus was present, a haemolytic type in 25 per cent., while in males this order of frequency was reversed. This lends some support to the view that the usual progress of the infection differs materially in the two sexes.

The protagonists of both views regard the symptoms of fever, general malaise, and tenderness over one kidney as always evidence of the existence of pyelitis, but I question whether this view is based on indubitable evidence. Cystoscopy combined with ureteral catheterization might give the evidence desired, but in the early stages such examinations are considered inadvisable. However, Frank Kidd has made two or three cystoscopic examinations in the earliest stages, and thus describes what he saw:

"The whole bladder wall was intensely engorged and inflamed and covered with portions of purulent membranous or fibrinous deposits and the mouths of the ureters buried in the general oedema of the mucous membrane."

I suggest that such oedema produces partial obstruction of the ureteric orifices with consequent distension of the ureter and renal pelvis, accompanied by congestion and tenderness of the kidney. I do not maintain that the pelvis of the kidney is never involved in these cases of urinary infection, but question whether the involvement is as frequent as is usually maintained.

From the successful effects of renal lavage, in which 4 c.cm. of 5 per cent. collargol are injected through a ureteric catheter into the renal pelvis, compared with the unsatisfactory results of ordinary vesical lavage, Frank Kidd considers he has clinched the argument in favour of primary, and persistent infection of the kidney, into which he has found the collargol penetrates. In view of the results I have obtained by injecting 0.5 to 2 per cent. collargol into the bladder, I am led to doubt whether his conclusions are justified. It must be borne in mind that 4 c.cm. of 5 per cent. collargol would make 40 c.cm. or about 1½ oz. of 0.5 per cent., and that the results attributed to renal lavage may possibly be due to the effect of the collargol on the bladder. I must, however, admit that I have obtained no such striking successes as cure after two or three injections. However, in Case 1 of my series the patient, who, previous to receiving the treatment I will describe, suffered from recurring attacks of fever, after treatment had no more of such attacks and has remained cured for over four years. It seems reasonable to conclude either that cystitis alone may produce all the symptoms usually attributed to the presence of pyelitis, or that pyelitis in this case was the result of an ascending infection. The other successful cases of this form of treatment justify the conclusion that, whether the infection ascends or descends, infection of the bladder alone is a very frequent condition in chronic cases, and that, even if the acute cases start in the renal pelvis, the infection there soon disappears, while that in the bladder

persists. Even cases of bacilluria have been cured by intravesical treatment.

In treating these infections a drug must be chosen which, while it may have a direct bactericidal effect *in vitro*, must not impede, and, if possible, should stimulate the natural methods of the tissues in overcoming infection. Collargol appears to possess these qualities.

Collargol, first used in the treatment of cystitis by Voelker and Lichtenberg<sup>1</sup> in 1905, was recommended to me for the treatment of a *B. coli* urinary infection by Mr. Percy Sargent in 1912. But although its beneficial action was reported so long ago, and although Frank Kidd speaks highly of its use in renal lavage, little use seems to have been made of it in recent years, partly, no doubt, owing to the unfavourable report on its bactericidal action by Marshall and Neave<sup>2</sup> in 1906, but mainly owing to the prevailing view that the primary and persistent seat of the infection was the kidney and renal pelvis. I have, however, myself investigated the bactericidal action of collargol *in vitro*, and found that in a dilution of 0.25 per cent. it will destroy *B. coli* in half an hour (a very conservative estimate of its potency), and that it is equally efficacious against streptococci. But its action in these infections is due not only to its bactericidal action, otherwise a 4 per cent. solution, which is quite well borne by the bladder—that is, can be retained without discomfort—would produce the best effects, whereas it will be found that 0.5 to 1 per cent. will usually prove more efficacious. The strength must be controlled by microscopic examination, and in the early stages pus must be regarded as beneficial and not the reverse. Indeed, in a case of bacilluria no progress can be looked for until pus cells begin to appear in the urine. When a case, after progressing favourably, tends to relapse, then usually it will be found advisable to reduce the strength of the collargol solution injected.

The technique of the treatment is simple, and in females can be carried out by a well trained surgical nurse, but unless sure of the nurse's skill the medical attendant should carry out the treatment himself. One of the two men in my series of cases carried out the later part of his treatment himself. A syringe, such as the ordinary large metal ear-syringe with a conical nozzle, capable of holding 2 to 3 ounces, is filled with the collargol of the desired strength (0.5 per cent. is a good strength to begin with, sterile water being used as a diluent); so that the syringe does not leak at the junction of nozzle and barrel. A soft rubber or gum-elastic No. 8 catheter with a conical proximal end, into which can be inserted the nozzle of the syringe, is passed into the bladder with aseptic precautions. Any urine in the bladder is drawn off and a sample kept for microscopic examination. The nozzle of the syringe is now inserted into the catheter and the collargol injected, after which the catheter, still attached to the syringe, is withdrawn, the collargol being allowed to remain in the bladder until the patient feels a desire to void it—that is, from twenty to sixty minutes. A small glass funnel, into which the collargol can be poured, may be substituted for the syringe. As the collargol solution is brownish-black and cannot be easily removed from any fabric on which it drops, care must be taken suitably to protect the bedclothes, etc.

It is not necessary for the patient to remain lying down after the injection, nor to remain in bed during the course of treatment, but confinement to bed will probably hasten cure, and in resistant cases should be insisted on. Injections are made daily until the urine, as shown by microscopic and cultural examination, has become sterile, or until success by this line of treatment seems improbable.

The number of cases—namely, 17—treated by me is possibly too small to base an optimistic estimate of the results obtainable if the treatment were more widely used, but it has enabled me to follow the urinary changes with the microscope, in many cases by daily examinations.

The 17 cases treated by me since 1921 were infected at the outset with the following varieties of bacteria: 2 cases with staphylococci only; 2 cases with *B. coli* and streptococci; 2 cases with *B. coli* and staphylococci; 11 cases with *B. coli* only. Eleven cases have been cured, in the sense that at the end of treatment neither pus nor bacteria were present in the urine, as proved by microscopic and

cultural tests. In 7 of these the urine was known to have remained sterile for at least a month. It was not possible to keep the remaining 4 patients under observation so long. Case 4 in the series has had three attacks, each of which has been successfully dealt with, the urine having been rendered sterile on each occasion for lengthy periods. There has, then, been a successful result in 64.7 per cent. of the cases, or, if Case 4 be counted as three cases, in 68.4 per cent.

Case No.	Sex and Age.	Private or Hospital.	Duration of Infection Prior to Collargol Treatment.	Organisms Present.	Length of Collargol Treatment.	Result.
*1	M.50	Private	6-7 years	<i>B. coli</i>	Not known	Cured.
*2	F.40	Private	Few days	<i>B. coli</i>	14 days	Cured.
3	F.48	Private	2 months	<i>B. coli</i>	2 periods of 3 weeks	Not cured.
*4	F.47	Private	6 or more years	<i>B. coli</i>	1st attack 14 days	Cured.
					2nd attack 19 days	Cured.
					3rd attack many weeks	Cured.
5	F.40	Private	5-6 days	<i>B. coli</i>	9 days	Cured.
*6	F.83	Private	1 month	<i>B. coli</i> and staphylococci	56 days	Cured.
7	F.18	Hospital	4-5 weeks	Staphylococci	10-14 days	Cured.
*8	F.35	Private	5½ years	Streptococci and <i>B. coli</i>	16 days	Cured.
*9	F.65	Private	3 years	<i>B. coli</i>	12 days	Cured.
10	F.65	Hospital	2½ years	<i>B. coli</i>	15 days	Not cured.
11	F.43	Hospital	1 month	<i>B. coli</i>	3-4 weeks	Not cured.
12	F.41	Hospital	?	<i>B. coli</i>	14 days	Cured.
13	F.33	Hospital	1 week	<i>B. coli</i> and staphylococci	1 month	Not cured.
14	F.47	Hospital	13 months	<i>B. coli</i> and streptococci	10 weeks	Not cured.
*15	F.49	Hospital	2½ years	<i>B. coli</i>	1 month	Cured.
16	F.66	Private	7 years	<i>B. coli</i>	16 days	Cured.
17	M.53	Private	7 years	Staphylococci	14 days	Not cured.

\* In these cases freedom from infection was known to have lasted at least a month. Case 10 had a relapse three months after treatment, when too late she was found before her condition had become a urinary infection. Case 13 was practically cured, but had a relapse a charge from hospital. The hospital cases, however, were usually not in as good general health as the private cases.

Unless treatment is continued until the urine is free from pus and sterile relapses are liable to occur. Macroscopic examination is certainly not sufficient, nor do I think we may be content with microscopic examination. Cultural tests are almost essential, although, in the case of a *B. coli* or streptococcal infection, the development of three or four colonies of *Staphylococcus albus* on the culture medium may indicate no more than infection from external parts during the passage of the catheter.

The following is a list of the cases with a very brief summary of the course of treatment.

Case 1.—F. A. N., male, aged 50. *B. coli* infection followed two months after operation by Sir John Thomson-Walker for removal of calculus from left ureteric orifice. Treated by various means, including vaccines and lavage, until 1921. Had several attacks of fever. Early in 1921 began treatment with 2 per cent. collargol. Improvement rapid, but exact time required to render urine sterile not known, as after the first few injections the patient administered the remaining injections himself. Has remained cured four years.

Case 2.—Mrs. G. *B. coli* infection with fever during convalescence from hysterectomy. Collargol 2 per cent. injections cured the condition in about fourteen days. Urine sterile three to four weeks later.

Case 3.—Miss N. Severe attack of pyelonephritis. Temperature 103° to 104° F. Pus and *B. coli*. Treated with potassium citrate and later with vaccines. Two months after attack collargol 2 per cent. injections begun. Treatment at first greatly improved condition of urine, but success was not maintained and treatment was discontinued. (Better results might have been obtained by reducing the strength of collargol.)

Case 4.—Mrs. N., aged 47, wife of Case 1. Had suffered from *B. coli* infection six years. Had *B. coli* bacilluria when treatment by collargol 2 per cent. was begun. Improvement began when collargol 1 per cent. was substituted. The urine then became sterile in fourteen days. Has subsequently had two reinfections very resistant to treatment, but was ultimately cured.

Case 5.—Miss B., aged 40. *B. coli* infection with frequent painful micturition for five to seven days. Temperature 99.4° F. Collargol 2 per cent. rendered urine free from pus and organisms in nine days.

Case 6.—Mrs. K., aged 83. Attack of fever suggesting influenza or appendicitis. Temperature 101° F. Pus, *B. coli*, and staphylococci in urine. Temperature normal three weeks after beginning of attack. Ten days later collargol injected. Urine not sterile till fifty-sixth day of treatment. Injections almost, but not quite, daily, the strength of collargol varying from 0.5 to 2 per cent., and even 4 per cent., but strong solutions made matters worse. Urine sterile many months after cessation of treatment.

Case 7.—Mrs. M., aged 18. Staphylococcus infection. In-patient in London Temperance Hospital for three weeks. Treated with oral administration of drugs. Collargol injections in out-patient department produced cure in ten to fourteen days.

Case 8.—Miss E., aged 35. Urine infected with streptococci and *B. coli*. Collargol 1 per cent. cured the condition in about a month.

Case 9.—Mrs. T., widow, aged 65. Cystitis since removal of an innocent intravesical growth in Guy's Hospital three years previously. Frequent micturition, pus, and *B. coli*. Collargol 1 per cent. injections. Urine free from pus and sterile after nine days' treatment. Treatment discontinued on the twelfth day; urine still sterile on the seventeenth day, and no return of symptoms up to time of her death from pneumonia six months later.

Case 10.—Woman, aged 65; in-patient in London Temperance Hospital. First had difficulty in micturition in 1918; cured April 12th, 1923. On April 19th painful micturition, pus, and *B. coli* in urine. From April 30th till May 14th collargol 1 per cent. daily. On June 15th only four colonies of staphylococci on agar inoculated with loopful of deposit. On May 23rd culture revealed a few staphylococci and *B. coli* in urine. She had no further treatment and was discharged. Three weeks later reported by medical attendant to have another attack of "cystitis."

Case 11.—Married woman, aged 45; in-patient in London Temperance Hospital. Hysterectomy, April, 1923. Just prior to operation urine "strong-smelling." On May 1st the urine contained pus and *B. coli*. Collargol 1 per cent. given for three to four weeks without much improvement. (Twelve months later no pus in urine, three or four colonies of *Staphylococcus albus* developed from loopful of deposit.)

Case 12.—Woman, aged 41; in-patient in London Temperance Hospital. Pus and *B. coli* in urine. Collargol 1 per cent. injections rendered urine sterile in approximately fourteen days.

Case 13.—Married woman, aged 33; in-patient in London Temperance Hospital. Febrile attack; pus, *B. coli*, and staphylococci in urine. On the tenth day, when the temperature had fallen to normal, collargol injections begun. Strength varied from 0.5 to 2 per cent. A month's treatment had not rendered the urine quite sterile, nor free from pus cells.

Case 14.—Married woman, aged 47; in-patient in London Temperance Hospital. Frequent painful micturition ten months prior to operation for a large uterine fibroid, which was followed by phlebitis. Urine examined two months after operation contained blood, pus, *B. coli*, staphylococci, and diphtheroid bacilli. Collargol injections persisted in for about ten weeks, with one or two intermissions, resulted in considerable improvement, but not cure.

Case 15.—Married woman, aged 49; in-patient in London Temperance Hospital. Operation March 1924 for removal of uterine cervix, colpopharynx and peritonitis. Had had discomfort in bladder for three years. On April 14th much pus and *B. coli* in urine. On April 19th injections of collargol begun and continued till May 12th, when neopentol 10 per cent. was substituted for the collargol. Treatment discontinued on May 15th, and patient discharged from hospital on May 22nd, when no *B. coli* were present in the urine.

Case 16.—Mrs. H., widow, aged 66. Had synovitis with effusion in left knee. Urine contained pus and *B. coli* (condition probably of long standing). No urinary symptoms. Collargol 1 per cent. injections rendered urine sterile in seventeen days. Sterile a month later.

Case 17.—M. de L. Long-standing urinary infection. At beginning of treatment blood, pus, and staphylococci present in urine in considerable quantity. Collargol 0.5 per cent. injections rendered urine sterile in twelve days. Bacteria but no pus present one week later.

While very well satisfied with the results I have so far obtained with collargol, and convinced of its efficacy, I do not suggest that equally good results might not be obtained with other remedies unused by me. Certainly the ordinary antiseptics used for lavage have not proved curative. What, however, I desire most to suggest to my medical brethren is, not the efficacy of any particular drug, but the efficacy of treatment of these infections through the bladder.

In conclusion, I desire to express my thanks to my colleagues Mr. James McClure and Mr. R. A. Kerr for permission to treat cases under their care in the London Temperance Hospital, and for their friendly encouragement during the course of the investigations. My thanks are also due to Messrs. John Bell and Croyden, Ltd., for greatly assisting me by obtaining for me a supply of collargol at a cost much below the usual market price.

## A CLINICAL STUDY OF RHEUMATOID ARTHRITIS.\*

BY

A. H. DOUTHWAITE, M.D., M.R.C.P.

THE following observations are based on examination of 50 patients suffering from rheumatoid arthritis, 38 of whom were females. Attention has been purposely directed more to the patient's general condition than to the state of the affected joints, which are only too apt, by their prominence, to absorb the interest of the physician to the detriment of the patient. Thus in every case, prior to the onset of joint pain, there had been a period, extending in one case up to two years, during which a gradual deterioration of health was in progress. This showed itself most frequently by loss of energy, both mental and physical, together with constipation, and loss of weight and appetite. In a few cases increasing pigmentation of the skin, so typical of this disease, had actually been observed before any painful symptoms had arisen.

No direct relationship could be traced between general diseases contracted in earlier life and the occurrence of rheumatoid arthritis. In 20 per cent. of cases there had been, however, an illness shortly preceding, and probably precipitating, the onset of the disease—a fact which goes to prove that an attack of rheumatoid arthritis is almost invariably dependent on a previous lowering of the general bodily resistance. Of these, influenza occurred in 8, bronchitis in 1, puerperal haemorrhage in 1.

## ONSET OF ARTHRITIS.

It is of great importance to note that in no case was more than one joint involved in the original attack. This was usually the wrist or one of the interphalangeal joints, which, having remained swollen and painful for a few weeks, completely subsided. This was followed, after any period from a few days to several weeks, by extension to other joints.

Particularly noteworthy are those symptoms referable to the involvement of the small joints of the spine and the neighbouring structures. Pain radiating over the occiput may be the very first symptom—in fact, 4 of my cases were originally sent to neurological out-patient departments, 2 diagnosed as neuralgias of obscure origin, and 2 as functional headache. The patients themselves may refer to this pain as headache, but actually it is quite distinctive, being frequently unilateral, intermittent and shooting in character, aggravated by rotation of the head, and following the course of the occipital nerves. When changes occur in the superficial joints, the diagnosis of this pain is clear, but before this it can only be suspected by exclusion, for changes demonstrable by the x-rays, though usually present in the later stages of the disease, cannot be looked for during the first few months. Girdle pains may be produced in like manner by involvement of the intercostal nerves.

Considerable difference of opinion exists as to the correct explanation of these symptoms. That the pain should be due to any pressure by bony outgrowth is inconceivable, for this does not occur, at any rate for several years. There are, then, two hypotheses left: one is that there is a direct infection of the nerve roots by the same process that gives rise to the arthritis; the other, that the nerve root is compressed by inflammatory swelling of the involved connective tissue in the joint neighbourhood, or that the inflammation extends directly into the nerve roots. Arguing on the analogy of the more superficially placed joints, the latter view is perfectly tenable, for indeed their early deformity is largely due to periarticular swelling. Furthermore, the nerves which are involved are usually those related to a diseased area of the spine—a fact which suggests a localized inflammatory process rather than one attacking them independently via the blood stream.

Skin.—The skin is moist, profuse sweating being present on the legs, feet, and palms of the hands. The discoloration of the skin, so admirably described by Kent

\* Thesis approved for the degree of Doctor of Medicine in the University of London (abridged).

Spender,<sup>1</sup> was present in 29 of my cases, of which 26 were females and brimmettes. It varied from a generalized brownish colour to a condition of discrete pigmentation, the spots averaging 5 mm. in diameter. Their distribution was very irregular, but chiefly evident on the forehead, abdomen, and extensor surfaces of the forearm. The possible association between such pigmentation and the constantly low blood pressure in these cases is unavoidable. Thus there seems little doubt that both melanin and adrenaline have common precursors which are protein derivatives. Halle has shown that tyrosine could be converted to adrenaline, and concluded that in the event of disease of the suprarenals this substance accumulated in the tissues and was oxidized to melanogen and finally to melanin. In a recent paper Spencer<sup>2</sup> reviews the subject of melanosis and gives a list of the probable chemical precursors of melanin, including tyrosine, a recognized antecedent of adrenalin. Arguing from the analogy of recognized endocrine disorders—for example, exophthalmic goitre and Addison's disease—it seems not unreasonable to assume that the general constitutional disturbance of rheumatoid arthritis may involve the suprarenal bodies, with depression of function and reduction of adrenaline output, with consequent lowering of blood pressure, increased melanin formation, and pigmentation. In 2 cases (males) psoriasis was present. In both exacerbations of arthritis were accompanied by aggravation of the skin disease. Five cases suffered from lupus erythematosus, which had followed the onset of arthritis by periods varying from three weeks to five months. The coexistence of these conditions appears to me, at least in the second case, to rest on more than a coincidence, and it is noteworthy that the trend of modern dermatological thought is to consider both eruptions as skin reactions to toxins arising from foci of chronic sepsis.<sup>3</sup>

**Cardio-vascular System.**—Rapidly of the pulse rate, a feature which has been stressed by many observers, was far less noticeable in this series than its remarkable daily fluctuations. Thus a pulse varying in daily rate from 65 to 110 was by no means uncommon in patients confined to bed. In no case was disease of the valves present. The blood pressure, however, in every case was found to be low; the following readings were typical of the series:

Age.	Systolic Pressure.	Diastolic Pressure.	Age.	Systolic Pressure.	Diastolic Pressure.
31	100	65	34	105	55
29	120	80	32	119	79
42	114	75	29	118	70

No striking changes in the blood occurred. The lowest erythrocyte count numbered 4,096,000, the highest 5,120,000. In all cases a leucopenia was present. A differential count showed a slight relative increase in lymphocytes.

**Nervous System.**—Mention has already been made of the pains referable to irritation of the posterior nerve roots. In 3 cases there was definite peripheral neuritis affecting the legs. With these exceptions, the knee-jerk was found to be unusually brisk at the height of the disease, with a gradual return to normal as the disease passed into a less acute stage.

**Muscular System.**—Muscular weakness and wasting appeared constantly, and usually there seemed to be a close relationship between the degree of inflammation of the joint and the associated muscular atrophy. In an appreciable number of cases, however, a different picture presented itself. An extensive and early muscular wasting had occurred which appeared unaccountable on the grounds of a disuse atrophy. Thus in one case in which the shoulder-joint had been painful for three weeks, but in which no abnormal signs could be detected apart from pain on movement, the deltoid, supraspinatus, biceps, and upper part of the trapezius were greatly reduced in bulk and had lost their usual firm consistency. They were weak in action but not tender to pressure. Such changes have received more attention in France than in this country, and are there regarded as reflex trophic disturbances. Possibly they may be explained as being due to a complete inhibition of those minimal motor impulses which normally produce tone in muscle.

**Gastro-intestinal Changes.**—The common assertion that achlorhydria or marked hypochlorhydria is an occurrence of extreme frequency in rheumatoid arthritis is totally unsupported by my results. The gastric contents of 30 patients were examined by the fractional test meal. In 27 the total and free acidity were within normal limits; in one case there was hyperchlorhydria, and in 2 cases definite hypochlorhydria. The rate of emptying was often delayed. Other workers on this subject<sup>4</sup> greatly stress the frequency of achlorhydria, and suggest that it plays a part in allowing infective organisms to pass unharmed through the stomach to the intestines, there to elaborate their toxins. This divergence of results can, I think, be explained, in the cases quoted by Coates and Gordon, by the fact that they used the Ewald's test meal, which clearly cannot give a true picture of the various phases through which the gastric contents pass. The total number of cases investigated by Hurst is not mentioned. The only other noteworthy change in relation to the digestive system was the nearly constant gastropnoia and enteropnoia as demonstrated by radiography. In all, except the hyperchlorhydric, the stomach was extremely low in position, atonic, and exhibiting feeble peristalsis. The colon showed scanty segmentation. There was no true intestinal stasis.

**Lymphatic Glands.**—In 4 cases enlargement of glands associated with the inflamed joints took place.

#### Examination for Origin of Infection.

Examination was made of: (1) the air sinuses of the skull; (2) the teeth (including x rays); (3) the tonsils; (4) the faeces; (5) the anal region for suppurating piles, etc.; (6) the vagina; (7) the prostate and urethra.

Dental and tonsillar infection proved by far the most fruitful sources, *Streptococcus longus* being cultivated in each case.

#### TREATMENT.

The following procedure was adopted with the six cases who were hospital in-patients: (1) Immobilization of joints in the acute stage, if possible by extension splints. (2) Eradication of septic foci. (3) Immunization by means of an autogenous vaccine. (4) Massage and passive movements. (5) Auto-serotherapy. The first, second, and fourth steps call for no further comment.

**Method of Vaccine Administration.**—In some patients any attempt to raise the vaccine dosage above a few million results in violent aggravation of the arthritis, probably as the result of sensitization to the foreign protein. In view of this fact the usual method of administration was not adopted, but before each injection of the main dose subcutaneously, a minute quantity (a quarter of a million) was administered intravenously in the hope of desensitizing the patient to the subsequent dose. Highly satisfactory results were obtained by this method, which furthermore allows of a much more rapid increase in dosage than is possible by the subcutaneous administration alone.

The symptoms, though subsiding to a certain point, failed to disappear completely; probably the antibodies were unable to gain access to the oedematous periarticular tissues. On this assumption, the following procedure was adopted. Three days after the final dose of vaccine 20 c.cm. of the patient's blood was withdrawn into a sterile vessel and allowed to stand in an ice-chest. The serum was then separated from the clot. The patient having been anaesthetized, serum was injected through a fine needle so as to infiltrate the swollen tissues right down to the synovial membrane, and finally a small quantity was injected into the joint cavity. On the following day in each case a very striking improvement was observed. The joints could be moved with little or no pain, the swelling had partly subsided, and subjectively the patients experienced enormous benefit.

#### CASE.

E. R., female, aged 36; admitted February 10th, 1923, with a history of pain starting in the finger-joints fourteen months previously. On admission there was swelling of all the small joints of fingers and hands and of the right tarso-metatarsal joint, together with well marked pigmentation, gastropnoia, and muscular wasting. Blood pressure 105 and 55.

A *Streptococcus longus* vaccine was prepared from the emulsified tonsils and treatment carried out as described. Before the injections of her serum she was unable to knit owing to the painful condition of the fingers. On the day following this treatment she was actively knitting with complete freedom from pain. She was discharged on April 10th free from pain, and six months later she wrote stating that she had had no further trouble and was busy with housework. Similar results were obtained with four other cases.

It is, of course, too early to speak of complete cure, but the results justify their inclusion here.

In this abstract I have necessarily omitted details of the very important general treatment, but would just mention that fresh air and sunlight baths (artificial in this country) often produce the most astounding improvement in refractory cases.

The widespread pessimism in dealing with rheumatoid arthritis is responsible for the existence of so many cripples who have been allowed to drift from bad to worse. If, on the other hand, treatment on the lines indicated is carried out, always bearing in mind that the obtrusive joint pains are but concomitants of a host of pathological changes throughout the body, great hope may be held out that rapid relief and ultimately complete cure will be achieved.

My thanks are due to Drs. Beppard, Freach, Inat, Ponlton, Mutch, and Symonds, for permission to examine and treat certain of their cases.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## THE SIGNIFICANCE OF HAEMORRHAGE IN CHRONIC UTERINE SEPSIS.

RECENTLY we have had admitted to the wards a case of unusual interest, illustrating the consequences of not recognizing the earliest sign of subinvolution of the uterus—namely, haemorrhage—and showing the efficacy of appropriate treatment.

The patient, aged 21, was admitted to hospital on April 29th, 1925, with a history that she had been confined nine weeks previously. She was in labour sixty-four hours; delivery was instrumental, and four stitches were inserted in the perineum. She bled for the first five weeks, then stopped for ten days, and breast three weeks after confinement. An abscess was opened in the right

On admission she was pale and anaemic; the breast was draining freely; the lochia still red. Temperature  $103^{\circ}\text{F}$ , pulse 104. On May 1st an intrauterine injection of pure glycerin was administered. The haemorrhage stopped a few hours after this treatment. On May 4th the intrauterine treatment with pure glycerin was repeated. Blood cultures were normal, but a cervical smear showed streptococci.

By May 6th the patient had been in the hospital seven days, and each evening the temperature had reached between  $103^{\circ}$  and  $104^{\circ}$ . It was thereupon decided to give four intrauterine injections of pure glycerin within the next twenty-four hours. We were then rewarded by seeing the temperature fall from  $104.6^{\circ}$  to normal and not rise again.

## Remarks.

The earliest sign of morbidity in this case was obviously the fact that the lochia did not lose their red colour as they ought to do by about the end of the first week. This condition should have been recognized as pathological. In other words, the case should have been treated as one of secondary haemorrhage. It should have received the same care and attention as bleeding from a septic amputation stump or any other septic wound. It has long been my contention that a woman after confinement should not be allowed to trickle for weeks for lack of appropriate treatment. She may receive ergot and donches, or be curetted or swabbed out with strong styptics; but none of these measures are as effective as the intrauterine treatment with glycerin.

I have now had the definite experience extending over many cases that if the lochia are still red by about the seventh to the tenth day this is a sign of secondary haemorrhage from the uterus. I find that glycerin is the best drug in stimulating the uterus to contract, and stops

haemorrhage far better than any form of intrauterine manipulation or medication.

In a very large number of cases I have had the satisfaction of seeing patients improve rapidly and their temperatures fall after three or four treatments in the twenty-four hours instead of once daily.

Medical Superintendent, St. Mary Abbots  
Hospital, W.B.

## CEREBELLAR ABSCESS.

The diagnosis and treatment of brain abscesses are sufficiently difficult to make each case interesting.

M. L., aged 20, domestic servant, had a history of chronic left otorrhoea for several years. Five weeks previous to being seen by me she was admitted to a hospital suffering from headache and earache. After two weeks she was removed home by her parents, too ill to walk. She was at home for three weeks, before being sent to the North Lonsdale Hospital.

When seen by me two days before admission she was lying curled up in bed in a dazed condition. She resisted examination or questioning, but answered slowly and correctly. Urine was being passed involuntarily. Coarse nystagmus on moving the eyes to the left was present. A provisional diagnosis of cerebellar abscess was made. She was admitted on May 11th, 1922, and the following is an extract from the hospital report:

"She lay curled up in bed on the right side, the head and neck slightly retracted. She complained of violent headache, and suffered from intractable vomiting. There was oedema over the left mastoid and left temporal areas. There was a little discharge from the left ear. There was no optic neuritis. Facial paralysis, not well marked, of lower half of face was noted. There was no incontinence of urine, but there was obstinate constipation throughout. The features were expressionless, passive, and wore a meaningless smile. The pulse was on the average normal and regular. The temperature was persistently subnormal."

Operation, May 15th, 1922.—The left mastoid antrum was opened and was found to contain pus. A considerable oedema had developed over the temporal region since admission, an exploratory trephine opening was made above the external meatus over the temporal lobe. No pus was found. An opening was then made over the cerebellum  $1\frac{1}{2}$  inches behind the external meatus and below the lateral sinus, a flap having been previously turned up. The bone, which was thin, was scraped through with a curette till the dura mater was reached. No pus was found on either side of the dura mater. A probe was then passed an eighth of an inch into the cerebellar substance, and about 1 oz. of foul-smelling pus gushed out. The abscess cavity was gently irrigated with warm saline solution till the solution returned clear. A soft rubber drain was then led through the soft tissues to the dura, but no drain was placed in the abscess cavity. The drain was removed in two days and not replaced.

A few days later the patient complained of headache and discomfort. Examination showed some swelling over the cerebellar wound. A pair of forceps passed into the external wound and opened gave exit to a drachm or two of pus. After that recovery was uneventful.

She left the hospital on July 21st, 1922, went to work a year later, and has been self-supporting since.

Dr. A. F. Rutherford was associated with me throughout in the treatment of this case.

Honorary Surgeon, North Lonsdale Hospital,  
Barrow.

## POISONING BY EUCALYPTUS OIL.

DR. SEWELL's case of poisoning by eucalyptus oil (*BRITISH MEDICAL JOURNAL*, May 16th, p. 922) reminds me of one I saw about fourteen years ago.

A young collier, who was also a pugilist, found himself on the morning of a fight suffering from a cold in the head, for which a friend advised a drop of eucalyptus oil. This unfortunately he interpreted not literally, but on the analogy of "a drop" of whisky, as understood in a colliery district in pre-war days to mean three-pennyworth. He therefore bought and consumed, as I ascertained later from the chemist, about 3 drachms of the oil, and set out for Liverpool, where the fight was to take place. During the short railway journey he fell asleep; at his training quarters he again fell asleep; having got into fighting kit and reached the ring, he once more relapsed into such profound slumber that he could not be roused, and was consequently taken back home and put to bed. I was called to him on the following (Sunday) morning. Except for a slight drowsiness he seemed none the worse; he had no pain, and no gastric or intestinal disturbance. In fact, I think he only sent for me as a precaution in the event of any official inquiry as to his condition in the ring the night before. He resumed his work in the pit as usual on Monday morning.

Here too the effect seemed to be entirely hypnotic, but delayed much longer than in Dr. Sewell's case, probably owing to the greater age of my patient and the fact that he was in hard physical condition.

# RUPTURE OF ABDOMINAL ANEURYSM SIMULATING ACUTE INTESTINAL OBSTRUCTION.

The comparative rarity of rupture of an abdominal aneurysm renders the details of the following case worthy of publication, particularly since the symptoms resembled those of acute intestinal obstruction. My thanks are due to Dr. W. B. Wishart for permitting publication.

A cotton twiner, aged 71, was perfectly well and following his occupation until noon of April 20th, when he complained of a severe pain in his back. Persistent faecal vomiting set in two days later; constipation was absolute from the onset of the symptoms. He was admitted to hospital on April 23rd, his temperature being 96° F., his pulse 120, and his general condition very poor. The anterior abdominal wall was rigid, very tender, and dull on percussion; the rigidity and tenderness were more marked on the right side; there was no visible peristalsis and no pulsation of the abdominal wall. In view of the history and the physical findings a diagnosis of intestinal obstruction was made. At an operation performed under local anaesthesia a pulsating aneurysm: the patient's grave condition curtailed further investigations, and he died three days after admission, and six days from the onset of symptoms. A limited autopsy was performed, when it was found that the whole of the small bowel was collapsed and lay in the left hypochondriac region. The right half of the abdomen was occupied by a large bluish-black retroperitoneal mass extending from the dome of the diaphragm down to the brim of the true pelvis. This proved to be a rupture of the right lateral wall of a fusiform aneurysm of the aorta, the size of a man's fist, extended from a point half an inch below the level of the origin of the renal arteries to a point just above the bifurcation of the aorta; the walls of the aneurysm, common iliac arteries, and the portion of the aorta proximal to the aneurysm were markedly atheromatous. The right kidney was polycystic, but no other macroscopic changes were noted in the abdominal organs. Another interesting feature was the almost complete suppression of urine.

Halifax Infirmary.

## British Medical Association.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### WESTMINSTER AND HOLBORN DIVISION.

##### Group Medicine in Practice.

At a meeting of the Westminster and Holborn Division of the British Medical Association, held at 86, Brook Street, on June 11th, a paper prepared by Dr. ADOLPH ABRAHAMSON on group medicine in practice was read. In the experience of every practitioner, it was said, cases occurred which did not fall into a definite category, and in which it was difficult to decide whether the symptoms were organic or "functional," and the relative importance of psychical and physical factors had to be carefully assessed. The practitioner's chief difficulty in these cases was the preparation of a systematic scheme of treatment based upon a comprehensive view of the patient—one which, while taking into consideration all the various factors, did not emphasize any one method. This ideal was quite possible of achievement by team work. The elaborate scope of modern methods of diagnosis had made specialization an obvious necessity; the failure to take full advantage of special knowledge and skill was a weakness for which team work could offer a prop. A vital feature in team practice was a conference at which all the members of the team who had seen the patient were present; this conference, if convenient to himself, was attended by the general practitioner who sent the patient for investigation and would be responsible for carrying out the treatment, and at it each member reviewed his opinion in the light of those of his colleagues; in this way his individual opinion might increase or decrease in relative importance when seen from other angles; some puzzling anomaly might become quite clear when assisted by the results of another specialist's investigation; and any tendency to obsession would be neutralized by the criticisms of less partial observers; thus a composite view was obtained.

Owing to lack of co-ordination it was impossible for individual specialists, in cases where two or three factors were playing a part, to be sure that the pathological element in their own particular region was solely responsible; but a team which was so composed that its routine examination necessarily scrutinized the large number of possible causes would not only ensure the large number of investigations in a very short time, but would, by collating all results, eliminate the danger of obsession by specialization, and yet take full advantage of each individual contribution.

The constitution of a diagnostic team might most conveniently be considered as consisting of three circles. The first, or inner circle, consisted of members who saw every patient as a routine procedure. Its composition was the most difficult problem in group organization. It should be as small as possible, and its members must be prepared to make many personal sacrifices and at times perform duties out of proportion to remuneration. The patient's point of view was important; the time he was prepared to give was usually limited to three days; anything not strictly indispensable must therefore be excluded. A patient was likely to object if subjected to a series of examinations which seemed to him mere repetitions. The ideal was so to systematize the inner circle that with a minimum of personnel the largest number of errors resulting from incomplete examination would be avoided. The medical director conducted all communications with the patient and his own practitioner, summarized the report from the patient's doctor, and the odds and ends of pathological and other information that might have accumulated for years; interviewed the patient, took his history, and made a general examination. The medical director could work most conveniently with the general physician of the group. At one interview the history of the case could be fully considered, the routine examination performed, and unnecessary duplication thus avoided. At this routine examination the patient was referred to the oculist, the laryngologist, and the dental surgeon. In many cases a negative report was returned, but in others the early stages of some general disorder might be covered; only an expert was justified in saying that the area which fell within his domain was normal. The pathologist examined the blood as regards the number and proportion of the cells, the haemoglobin content, and the Wassermann reaction, and made a routine examination of the urine. The radiologist screened the cranial sinuses and the chest, and took radiograms of the teeth if instructed to do so by his dental colleague.

The outer circle included the pathologist, radiologist, oculist, and laryngologist in capacities supplementary to their routine work. A further advantage, the importance of which could hardly be overestimated, was that a need for special pathological investigation might be felt by the regional specialists whose interview preceded that with the pathologist. The outer circle also included a general surgeon, a gynaecologist, a neurologist, a cardiologist, a biochemist, a psychotherapist, a physician experienced in tropical diseases, a dermatologist, and a paediatrician.

The outermost circle was a group of very highly specialized individuals to whom patients were referred on comparatively few occasions. It included an orthopaedist and a proctologist. A physiotherapist and a balneologist were sometimes consulted rather for advice on treatment than for diagnosis. This outermost group was indefinitely extensible.

The patients who were sent for examination fell into the following categories: (1) Those who had already undergone a great deal of examination and treatment without relief but nevertheless believed that some remedy could be found for their perpetual symptoms. These would improve their doctors to try something new, and group diagnosis could at least claim to be new. (2) Those who were "seedy" rather than really ill and felt that they were unreasonably handicapped in the battle of life. (3) Those who were genuinely, if not alarmingly, ill, yet without any obvious explanation. (4) A small group with the phobia of serious disease, where it was hoped that a thorough investigation might allay anxiety. (5) A very

## GROUP MEDICINE IN PRACTICE.

small group composed of patients who were very gravely ill and perhaps in the final stages of some mortal disease. A particular symptom would rarely allocate a patient to any one of these categories, and symptoms often seemed to bear no relation to the cause. Still it was with symptoms that patients presented themselves, and for this reason the anamneses of the first 210 patients had been analysed.

The complaint most frequently made was "loss of energy": 35 patients complained of this symptom, with such variations as "tiredness," "always feeling tired," and so on. "Indigestion" was the complaint in 24 instances. Abdominal pain was the presenting symptom in 34 cases and headache in 17. It will be observed that exactly 50 per cent. of the patients were comprised under these four headings—loss of energy, indigestion, abdominal pain, headache.

Seven patients were sent up for attacks of unexplained pyrexia; 7 for depression and irritability; 7 also were victims of pathophobia; 4 feared cancer, 1 pulmonary tuberculosis, and 1 lupus of the nose. One was a false cardiopath, a qualified medical man, who had already seen over sixty doctors, including as he himself stated, all the cardiologists famous and infamous, reputable and disreputable. It was regrettable, but hardly surprising, that he was not convinced by all our unexpected prising. Six patients complained of dizziness or giddiness; 5 of diarrhoea, and 5 of pain in the back—a rather unexpectedly small number for this very common symptom. Pain in one or more joints was the complaint in 8 cases. Loss of weight was the sole complaint in 4 cases; pain in the chest also in 3 instances. Shortness of breath, nervousness, or vomiting, each in 3 instances. Two complained that they "always felt ill," whilst 7 could only be described as polysymptomatic, an invitation to describe their chief symptoms producing a torrent of place. Three patients suffered from defective vision; 2 came for obstinate skin eruptions; 2 with shaking of the limbs—both paralysis agitans; 2 with intermittent hydrarthrosis; 2, both children, with incontinence of urine. The remainder was made up of single cases of obesity, diplopia, enlarged glands, intolerable itching, soreness of the tongue, bad taste in the mouth, contraction in the throat, haemorrhage from the ears, nose, and eyes, loss of voice, swelling of the legs, swelling of the hands, numbness of the feet, stiffness of the face, pain in the groin, and fits.

Only 6 of these patients were suffering from some obvious disorder, easily detected at the preliminary examination by medical director and physician, so that any further investigation was superfluous—namely, 2 cases of paralysis agitans, a patient who complained of obesity, and cases of acne, furunculosis, and uterine fibroid respectively, the last demanding collaboration between gynaecologist and physician only to decide whether operation might be undertaken with safety. Of the rest only 31 presented serious organic disease.

One patient was suffering from acute suppurative cholecystitis, one arrived in the terminal stage of uræmia, a third had gall stones and hydronephrosis. Two patients with cephalitis lethargica presented an interesting contrast—one died in the early acute stage, the other had been ill for over twelve months with vague symptoms of exhaustion labelled "neurasthenia" due to the late Parkinsonian syndrome. The other serious cases included colitis of twenty years' standing. He had reached the stage of the late Parkinsonian syndrome. The other serious cases included 2 of cholecystitis, 2 of gastric ulcer, 2 of duodenal ulcer, 1 of aneurysm of the thoracic aorta, 2 of pernicious anaemia, 2 of early pulmonary tuberculosis, 1 of generalized carcinomatosis, 1 of infective endocarditis, 1 of mycosis fungoides, 1 of optic atrophy, 1 of tuberculous laryngitis, 1 of thrombosis of the pelvic veins, 1 of cerebral syphilis, 1 of pituitary tumour, 1 of malignant disease of the spine, 1 of paraplegia due to a neurofibroma of an anterior spinal nerve root, 1 of Jacksonian epilepsy, 2 of major epilepsy, 1 of tuberculous tenosynovitis, and 1 of disseminated sclerosis.

Thus approximately 80 per cent. of the patients were not regarded as suffering from any severe disease although their disorders were responsible for a great deal of unhappiness and ill health.

Few of these patients gave sufficient positive evidence of disease in a very limited field to justify therapeutic measures directed along one channel alone.

In a case of giddiness, wax in the ears proved to be entirely responsible; dental sepsis alone required treatment in 4 cases. In 4 the symptoms were due to uncorrected or improperly corrected errors of refraction. One case of headache was explained by nasal obstruction, another by Eustachian catarrh, and in a third the rhinologist and oculist agreed to divide the responsibility. But in the large majority of cases the difficulty was to assess the relative importance of psychical causes and of focal sepsis, for these two factors were in some degree responsible for the greater bulk of the symptoms.

The psychical element was prominent in 59 cases. In 28 of these the symptoms were regarded as being entirely

psychical in origin or as presenting so overwhelming a psychic trend that the trivial organic elements were negligible or were best left alone. In the remaining 31, organic factors were considered to play an important part. These included endocrine disturbance, intestinal toxæmia, eye-strain, septic teeth, septic tonsils, uterine displacement, pancreatic insufficiency, chronic cholecystitis, and organic nervous disease. In 10 cases the diagnosis of vagotonia was considered. Now this diagnosis was all-sufficient to those sanguine physicians who saw a definite syndrome in overactivity of the parasympathetic nervous system, but, even if its reality were admitted, it was still uncertain whether this overactivity was determined by a primary constitutional weakness of the endocrine system or a disturbance secondary to some septic process. In any case the indications for an all-round consideration of the patient were emphasized.

Enteroptosis was diagnosed in 14 cases. Again the question was whether enteroptosis alone could produce symptoms, or was a susceptible nervous system a necessary factor? Endocrine disturbance was diagnosed in 14 cases, combined in 7 with enteroptosis, in 6 with intestinal toxæmia, and in 1 with nasal sepsis. Besides the case already mentioned where isolated infection was responsible for symptoms, focal infection was noted as follows:

Dental, biliary, nasopharyngeal, intestinal, and bladder infections in various combinations were found in 10 cases. Septic tonsils alone were regarded as responsible in 2 cases of otherwise unexplained pyrexia, in 1 case of acute nephritis, 1 of iritis, 1 of sciatica, and 3 of chronic tiredness; septic tonsils with intestinal infection were present in 7 cases. The uterus was incriminated as a sole factor in 2 cases. Secondary anaemia was the cause, in 4 cases. In all, intestinal toxæmia was regarded as the cause, and from the results of appropriate treatment, probably with justice. Chronic appendicitis was the diagnosis in 5 cases, and the diagnosis of a post-operative abscess was made and confirmed in a patient who had been operated upon for appendicitis eight months previously. Congenital defect of the colon was the radiographic report in one case, a diagnosis which otherwise could not have been made, but which certainly fitted in with the clinical picture. Spasm of the colon was seen twice, in both instances evidently as a functional condition of the gut after tropical dysentery. Atonic dyspepsia was diagnosed on five occasions, hyperchlorhydria on three. Hyperthyroidism and myxoedema not even appears twice only, dyslipitularism once, and myxoedema not even on one occasion.

Finally, group diagnosis contained a nucleus of very great value for research. Much had been written on the importance of preventive medicine and the urgency of recognizing disease in its earliest stage. It was only in some scheme of group diagnosis that real hope of this early recognition resided. In such a scheme justifications, some found for the insistence on routine examinations, some of which were negative and apparently of no importance so far as the present day was concerned. A different prospect opened up when the value was realized of documentary evidence that certain symptoms or signs were present or absent at an expert examination five or ten years previously. Such investigations on a large enough scale could hardly fail to discover certain common denominators to act as signal posts; and it was possible that by such exhaustive investigations the cause of many obscure diseases might be revealed, perhaps even that of malignant disease itself.

## Demonstrations.

Dr. JOEKES and Dr. S. GILBERT SCOTT gave a joint demonstration of passing the duodenal tube to draw off the contents of the gall bladder for diagnostic purposes. By means of the x rays the tube could be watched passing down into the stomach, and through the pylorus into the duodenum. Its exact position in the duodenum could be checked. By injecting air through the tube it was possible to demonstrate the gall bladder, and in this way to assist in the detection of gall stones. In other cases the opaque (barium) emulsion, as used in gastric work, was injected direct into the duodenum; this method sometimes gave valuable results. It was pointed out that conjoint work in diagnostic research was a great asset, and was best achieved where a number of specialists were working together in one building in close touch with each other. Mr. MONSON gave a demonstration illustrating the use of pyelography in the diagnosis of renal disease.

# A GERMAN TEXTBOOK OF HUMAN PHYSIOLOGY.

In the fourth edition of Zuntz and Loewy's *Lehrbuch der Physiologie des Menschen*, the gap in the editorial staff occasioned by the death of Professor Zuntz was filled by Professor W. TRENDLENBURG, who also has since died. Many physiologists in Germany, Austria, and Sweden have written sections dealing with those special branches of the subject to the knowledge of which each has contributed, or in which each is particularly interested. The book appears therefore at once as an authoritative work, and yet at the same time it has not succumbed to the danger of losing its unity and individuality—a danger always imminent to the production of such a volume.

There are, however, several points to which perhaps criticism may be directed with advantage. In the chapter on the morphology and chemistry of the blood no mention is made of the physiological variations in the numbers of leucocytes with age. The omission is common in textbooks of physiology, although a knowledge of the normal figures is necessary for the clinical interpretation of blood counts in diseases of childhood. The statement is made in the following chapter that adrenaline has no action on the pulmonary blood vessels. It is, however, a well known experimental fact that when this drug is added to the isolated heart-lung preparation a well marked rise in pulmonary pressure occurs. This is interpreted as being due to vaso-constriction in the pulmonary area—an interpretation which is quite justified in the absence of proof that it can be accounted for entirely by the hot wire sphygmograph might have been included with advantage as affording a simple and accurate means of determining pulse-wave velocities. Neither is attention directed to the auscultatory method of determining systolic and diastolic pressures in man.

A short chapter is devoted to the physiology of lymph. The salt content of this is stated to be higher than that of the serum (0.426 per cent. chloride in the lymph against 0.396 per cent. in the serum). It was shown, however, by Colmstein that this discrepancy was due to the serum solids not being taken into consideration in the estimations, and it is clear from the figures that a difference of 7 per cent. in the total solids of serum and lymph would account exactly for the difference of 0.03 in the percentage of chloride. In any case the discrepancy seems too large to be accounted for solely by a membrane equilibrium, as is suggested on page 226. In the same chapter an obvious misprint occurs on page 228, where 0.5 to 0.75 per cent. is said to be the quantity of reducing substance in the cerebrospinal fluid. In the paragraph describing Humphry Davy's method of determining residual air it should, for the sake of clarity, have been mentioned that rebreathing the indifferent gas must begin at the end of deepest expiration.

The chapter on urine and urine secretion falls below the general standard of excellence of the remaining chapters of the work under review. Many inaccurate statements and several important omissions are to be noted. We do not like to think of "ausgespuckter Speichel" as being a normal means of water elimination. In directing attention to the inability of the kidney to retain chloride absolutely even when this salt is being lost to a large extent through excessive sweating, it would seem desirable to mention the symptoms which are liable to ensue when the thirst is quenched under these conditions by copious draughts of water. Again, in dealing with the excretion of phosphorus, lactic acidogen is mentioned without any explanatory qualification. Anyone who has used the urease method extensively will take exception to the statement on page 345 that "an exact and at the same time convenient method of estimating urea in urine does not exist."

On page 350, and again on page 354, the statement is made that "it is sufficient to cut off the arterial supply to the kidney for one minute to bring about cessation of urine secretion for one hour." The true interpretation of this old observation of Heidenhain has been shown comparatively recently by Marshall to be that a reflex vasoconstriction is caused by pressure on the renal sympathetic twigs during the compression of the artery. If this is zealous during the compression of the artery, it is possible that the action of phlorhizin on the kidney is to cause it to secrete the sugar presented to it in the blood, and that there is no need to assume that the kidney manufactures a part of the sugar out of a precursor, as is suggested on page 351. The statement "If the kidney is excised and depends on the method of perfusion. If a heart-lung preparation is used as the propulsive mechanism a copious flow of urine is obtained. Exception must also be taken to the remark that stimulation of the vagus leads to an increased flow of urine. The statement is based on Ascher's work, but anyone who has read the paper by Ascher and Pearce on this subject cannot fail to reach the conclusion that no evidence whatever in favour of a direct action of the vagi on the kidney has been produced by them. Again, a blood dilution cannot be stated to be the cause of water diuresis in the presence of experimental evidence that no hydraemia accompanies it. In directing attention to the condition of diabetes insipidus in man it would have been instructive to have mentioned the specific antidiuretic action which extracts of the infundibular lobe of the pituitary body have in this disease. Several other points in this chapter call for comment. The vascular supply to the tubules is stated erroneously to be derived partly in a direct manner from the renal arteries—that is to say, without previous passage through the glomeruli. Fig. 102 would be more truly representative of the anatomical conditions obtaining in the lumbar and sacral cord, as stated on page 363, but are situated in the mid-pontine region. The defects to which attention has been directed, however, will appear small in comparison with the many excellent qualities the book possesses. It is a pleasure to see a section devoted to the local regulation of the number and width of the capillaries, and extremely useful and instructive to be presented with an exhaustive table giving the gross analysis and calorific value of foodstuffs used by man.

The illustrations and printing are excellent, and both authors and publishers are to be congratulated on the production of the fourth edition of this well known textbook.

## WHEELER'S "OPERATIVE SURGERY."

SIR WILLIAM WHEELER'S *Handbook of Operative Surgery* is passing through a stage previously reached by earlier works on the same subject. Originally a manual for students performing operations on the dead body in preparation for examinations, it is being transformed into the nucleus of a good work on operative surgery for young surgeons. Such a change is easily explicable, for circumstances connected with the restricted supply of bodies have effected an alteration in the courses of instruction that was overdue; Farabœuf's point of view is no longer that of the operating surgeon. So it comes about that the first fifteen pages of the volume are devoted to methods of anaesthesia, largely "local." Ligature of arteries, as an anatomical exercise, occupies fifty pages; this is followed by an account of blood transfusion, and so on. Some sections of the book are very much up to date—for example, the method of aseptic surgery includes a good deal of empyema, the "operative" surgery includes a good deal of after-treatment; space is devoted to Frank's gastrotomy which is disproportionate in view of its limited use.

*Handbook of Operative Surgery.* By Sir William Ireland de C. Wheeler, B.A., M.D. Dub. Univ., F.R.C.S.I., F.L.C.S. Hon. Fourth edition. London: Baillière, Tindall and Cox. 1925. (Demy Bro., pp. xvi + 441; 228 figures. 15s. net.)

*Lehrbuch der Physiologie des Menschen.* Herausgegeben von W. Trendelenburg und A. Loewy. Vierte Auflage des Lehrbuches von Zuntz und Loewy. Leipzig: F. C. W. Vogel. 1924. (Sup. roy. 8vo, pp. xiv + 788; 280 figures, 2 plates.)

application (there is a mistake in the legend of Fig. 231); a student might gather that Finney's operation is used for congenital stenosis. The distribution of the illustrations is uneven: two figures are devoted to the cure of persistent vesical fistula and there are none to accompany the account of abdominal hysterectomy. But, as we have said, it is a book in transition.

#### STATICS OF THE FEMALE PELVIC VISCERA.

In the second volume of *The Statics of the Female Pelvic Viscera* Dr. R. H. PARAMORE continues the study of the subject to which he has devoted so much painstaking attention. In the first volume, it will be remembered, he discussed the question as to how, from the anatomical and physiological points of view, the pelvic viscera are supported in position in the pelvis. In this volume he presents the evidence gleaned from the history of a century of operative treatment. The volume is divided into four parts. The first deals with the inception of plastic procedures, Marshall Hall's operations, the vaginal plecting operations of Jobert, electrolysis and cauterization of the vagina, extirpation of the womb, and Baker Brown's operation. The second part is entitled "The rise of plastic procedures: the amputation of the cervix and perineorrhaphy." Here the work of Huguier, Rizzoli, Küekler, Duenn, Milne, Bantock, Tait, Thomas, and Emmet is reviewed. Part 3 discusses the "Rise of vaginal operations and the confusion and scepticism of the eighth decade." It covers the work of Marion Sims, Whitehead, Duncan and Hart, Hegar, Emmet, Hewitt, Le Fort, and describes their methods of treatment. The last part brings the review down to 1899 and deals with colpo-perineorrhaphy, and the conception of prolapse as a hernia. The operations of Simon, Hegar, Martin, Bisehoff, Winekel, Pozzi, Garrigues, Hart and Barbour, Kelly, Herman, and others are described and discussed.

As a contribution to the history of gynaecology this volume of 400 pages of fairly close print is of interest and value. As an argument in favour of the author's conception of the causation of prolapse—which, briefly, is that it is due to a loss of equilibrium in the realm of abdominopelvic dynamics—it is too long and too elaborate. Few operating gynaecologists will, we suspect, have the industry to read through a book of this size, and it is doubtful whether those who do will find that they have reached any definite destination at the end of it. Our frank opinion is that Dr. Paramore has rather confused the issue by the prolixity of his discussion. All through he gives the impression that he believes himself to be practically the only gynaecologist with anything like a correct conception of prolapse. His position is, indeed, like that of the proud old mother, who, when watching her son's regiment march past, remarked, "They're a' oot o' step but oor Jimmy." With great earnestness Dr. Paramore reviews the opinions and methods of the array of distinguished gynaecologists whose names have been already mentioned. He deals faithfully with them, one and all, exposing the fallacies of their views and assessing the contribution which they made to the development of the modern conception of prolapse and of the present lines of treatment. He is unsparing in his analysis, as will be seen from the following quotation from his introduction.

"Opinion to-day is transitional, uncertain, unbalanced. Many operating gynaecologists, it must be admitted, as far as prolapse is concerned, appear in doubt, are indefinite in their utterances, take refuge in ambiguities, and often are clearly at sea. They teach the maxims of the schools and teach them sedulously and with conviction—dogmatically, tenaciously, as scholasticism insists. But these maxims, when examined, are but simulacra of truths; they are the results of tradition, erroneous reasonings, and empiricism. The doctrines they embody are contradictory, equivocal, evasive, mystifying. They lead to blind ends, and confusion. They divorce prolapse as a disease from general biological laws. They lead to no unity of thought—that man is individual. Frank avowals of this are rare, but occur—few men willingly admit their difficulties."

Dr. Paramore is evidently one of the few, for on page 362, after stating that "Garrigues seems to have got into a muddle," he adds—

in a muddle *once* my-self." (The italics are not in the original.)

One other quotation will show exactly the attitude taken up by Dr. Paramore: "The cause of prolapse is scarcely known or taken into account by the majority of operating gynaecologists." This being so, it is difficult for a modern gynaecologist to attempt to review the book, nor indeed is it necessary to say more. It would be easy, but unfruitful, to criticize various points in the volume, but enough has been shown to indicate the scope of the work and its praiseworthy intention.

#### MARY PUTNAM JACOBI.

*The Life and Letters of Mary Putnam Jacobi*,<sup>1</sup> edited by RUTH PUTNAM, gives the very human story of a pioneer, who was to the women of America what Elizabeth Blackwell, Sophia Jex-Blake, and Elizabeth Garrett Anderson were to the medical women of England. Mary Putnam encountered difficulties similar to theirs in breaking into the profession, and, like them, she succeeded, in spite of opposition that none but exceptionally well endowed women could have overcome.

The book relates incidents of her childhood, quotes letters in which she recounts her life in Paris as a medical student, records her professional activities in New York, her married life, and her death. Her father was the founder of G. P. Putnam's Sons, the famous publishing firm, and it was during his early endeavours to establish an English branch that Mary Putnam was born in a house in the Euston Road in 1842. When she was 6 years old the family returned to New York.

One of the striking features of her father's attitude to his children was his endeavour to induce them from an early age to think and act for themselves. The spirit of self-dependence fostered by her father determined her career, in spite of initial lack of encouragement from both parents. For three years she studied chemistry intermittently at the New York College of Pharmacy, and received a degree in 1863. Later in the same year she was entered as a student in Philadelphia at the Women's Medical College of Pennsylvania, and received a doctorate the following spring. She obtained some hospital experience in Philadelphia, and then went to the New England Hospital in Boston, where she worked for some months. Various "openings" were then suggested for her, but she hoped to begin private practice in New York. The assassination of Abraham Lincoln and the conclusion of the great Civil War occurred about this time, and these events probably combined to carry thoughts to national planes and inspire great ambitions in confident and earnest minds.

Mary Putnam found that Dr. Elizabeth Blackwell and her sister had already in their own country gone far in their medical work. They had succeeded in establishing a dispensary and infirmary in which women who had obtained some medical education could obtain clinical instruction. The available experience was inevitably very meagre, and Mary Putnam decided that not only was it insufficient, but that she must aim at the best obtainable.

Her father's hope that she would find ample scope for her mental activities without leaving the family circle was disappointed, and in September, 1866, she set sail for Havre. She was then in her 24th year, and possessed by the resolve to enter the École de Médecine, and, if determination and the will to succeed might be rewarded, to obtain the doctorate. Her letters from France, full of a vital interest in all the affairs of her daily life, were written with the intention of enlivening her mother's life, at that time narrowed and uneventful. The first six months in Paris were spent at the Lariboisière and the Salpêtrière, but in January, 1868, she was admitted to the École de Médecine; she was the first woman to gain admission. From then on her career was attended by every scholastic success. The same confidence as characterized her earlier years was evidenced in all she undertook. Her studies were carried on during the momentous events of the Franco-Prussian war, the deposition of an emperor, and the revival of a

<sup>1</sup> *Life and Letters of Mary Putnam Jacobi*, Edited by Ruth Putnam. New York and London: G. P. Putnam's Sons, The Knickerbocker Press, 1925. (Med. 8vo, pp. xi + 361; 9 plates, 15s. net.)

<sup>2</sup> *The Statics of the Female Pelvic Viscera*, by R. H. Paramore, M.D., F.R.C.S. (Eng.). London: J. A. Lewis and Co., Ltd., 1925. (Demy 8vo, pp. xx + 424; 58 figures, including 35 plates. 24s. net.)

republic. In July, 1871, she completed her examinations, and her thesis gained the highest commendation—"extrêmement satisfait." She frequently met Miss Garrett (Dr. Garrett Anderson), who was doing post-graduate work in Paris, and often mentioned her in her letters home.

Just before her final examination she received an urgent request from Dr. Jex-Blake, then in Edinburgh, to go to Edinburgh to prepare the women students for the examinations in anatomy. Mary Putnam, after prolonged consideration, felt that the time had come when the claims of home must be recognized, and so regretfully refused this offer. By the end of 1871 she was back in New York, now fully qualified in her profession, and still only 29. She was immediately admitted as a member of the Medical Society of the County of New York. The president of the society who bade her welcome was Dr. Abraham Jacobi, her future husband. She was appointed professor in the Women's Medical College, and immediately took up her duties. The lack of scholarly foundation and mental equipment which she found in her students surprised her, and in a moment of impatience she felt disposed to resign her appointment. An encouraging letter from Dr. Elizabeth Blackwell, then living in England, counselled prudence and patience, and persuaded her to remain and do her best.

In 1872 the happiness of the Putnam family was clouded by the sudden death of George Putnam. He had been ever ready with understanding sympathy with his children, even when their desires and ambitions were greatly in advance of his epoch. The following year Mary Putnam was married to Dr. Abraham Jacobi, and the next ten years were passed in happy home life and in professional duties, which she still pursued with unabated ardour. The tragedy of their life was the death of their son in 1883. The one remaining daughter became doubly precious to her mother, who gave up much time to supervising her education.

In 1888 she resigned her chair in the Women's Medical College, and gave more time to private practice. She was an ardent advocate of woman suffrage, and did much to forward the cause. After six years of invalidism, during which her mind continued active in spite of great physical disability, she died on June 10th, 1906. "She filled the time allotted to her so full of work, of affection, of helpfulness, and of hopefulness that its tale of existence is not recorded in its calendar days. That in so doing she widened the scientific outlook for all women may be counted as sufficient achievement to give her honour."

#### GUY'S HOSPITAL REPORTS.

THE first place in the new number of the *Guy's Hospital Reports*<sup>2</sup> is given to Mr. R. P. Rowlands's admirable "In Memoriam," with a characteristic photograph, of that arresting personality W. H. A. Jacobson, who did good by stealth, was a devoted friend to Guy's students, a wonderful teacher for twenty-four years in the outpatient room, and withal was very human and full of apparent superficial contradictions, mannerisms, and eccentricities. Of the nine other articles two are distinctly medical and the others surgical or dealing with specialties. Sir Charters Symonds describes the evolution of the short tube for the treatment of oesophageal stricture he invented about forty years ago with the help of his then dresser, Mr. B. Campbell Gowan. It cannot be often that father and son have written articles in the same volume, and rarely, if ever, in the same quarterly instalment, of these reports; on a basis of physiology and common sense Dr. C. P. Symonds writes clearly on the etiology and classification of the common neuroses which are divided into the anxiety neuroses, hysteria, and neurasthenia. An article on nervous symptoms due to alkalaemia and renal insufficiency following obstruction in the region of the pylorus, and the alkaline treatment of duodenal ulcer, is introduced by the editor, who, after mentioning the discarded hypotheses of the causation of gastric tetany, points out that the two principal factors are alkalaemia, shown by low chloride

and high bicarbonate content of the blood, due to the loss of hydrochloric acid entailed by vomiting, and renal insufficiency, as shown by the excess of urea and creatinine in the blood; three groups of cases are then described, by Mr. L. W. Houghton, Dr. J. F. Venables, and Mr. N. L. Lloyd respectively, presenting uraemia following obstruction near the pylorus, alkalaemia due to the alkaline treatment of duodenal ulcer, and pyloric obstruction with alkalaemia and renal insufficiency but without nervous symptoms. The 425 gall-stone cases admitted into Guy's Hospital between 1895—when gall-stone surgery began—and 1915 are analysed from a surgical point of view by Mr. W. E. Tanner, who concludes that while the mortality of cholecystectomy and cholecystectomy is the same, the experience that 9 per cent. of the patients who have undergone cholecystectomy may require a second operation does not justify the increased immediate risk of removing the gall bladder in every case. A method of treating grave peritonitis is described by Mr. J. Gaymer Jones; the affected area of the peritoneum is slowly irrigated by saline solution, introduced by a Carrel tube at the rate of one drop a second, and removed, together with exudate, by suction into a Woulfe's bottle. Meningitis of nasal origin is the subject of an article by Mr. W. M. Mollison, who has fortified his own experience by numerous references to other authorities. Mr. Vernon E. Lloyd contributes a clinical study of polypi of the prostatic urethra and their relation to chronic prostatitis, and Mr. Philip Turner analyses the results in fifty cases of trans-septal orchidopexy for imperfectly descended testis.

#### NOTES ON BOOKS.

IN his book, *Food and the Family*,<sup>1</sup> Professor V. H. MOTTRAM has succeeded in explaining a modern physiologist's views about diet in an unusual way. The book is intended for the lay reader, and its object is to translate into ordinary language the knowledge of food economy and food hygiene gained by recent scientific research. The translation is enlivened by many epigrams, and the whole tale told in a breezy if not always soberly accurate fashion. To give an example—speaking of the food value of eggs, Professor Mottram says:

"Admiration of eggs is absurd. Someone has even applied—a doubtful compliment—the following to them:

'Treasure-houses, wherein lie,  
Locked by angel's alchemy,  
Milk and hair and blood and bone.'

Were they like dukes in King Goodheart's days, three a penny, their praises would be sung by every writer on food. But they are extremely dear and should be left to millionaires, invalids, and children" (p. 212).

The second chapter, entitled "Some food fads," gives a very fair, albeit sprightly, discussion of such cults as vegetarianism and Fletcherism, and pauses to weigh the pros and cons of alcohol. In the ninth chapter the food values of a number of common foodstuffs and their value as sources of the elements of a diet are impartially considered. There are two questions about food which seem to be disturbing many people at present—first, in what types of food are vitamins present and which vitamins are where? and, second, how do the physiological values of certain types of food compare with their market price? Both these questions are well answered in this book, which we think will serve a very useful purpose in translating the cold logic of the physiological laboratory into attractive and readable journalism.

*Röntgen Diagnosis and Therapy*,<sup>3</sup> by Dr. ARTHUR C. CHRISTIE of Washington, U.S.A., is an elaboration of a book by the same author published during the war. In the first sixty odd pages we have a very concise description of apparatus, of the dark room, of the x-ray tube, and of electrical terms. It is an admirable introduction to the subject and is written in very plain and simple language. To this succeeds the main portion of the book, which is a rapid survey of x-ray diagnostic work, and very largely depends for its value on the numerous radiographs by which it is illustrated. On the whole these are sufficient for their purpose, even if some of them are not very good, having, it would appear, lost not a little in reproduction. The letterpress is clear, and the points of differential diagnosis are well stressed and distinctly

<sup>1</sup> *Guy's Hospital Reports*, vol. 75 (vol. 5, fourth series), No. 2, April, 1925. Edited by Arthur F. Hurst, M.D. London: Wakley and Son (1912), Ltd., 1925. (Med. 8vo, pp. 125-248; 1 full plate, 16 figures. Annual subscription 42 2s. for volume of four parts; single numbers 12s. 6d. each.)

<sup>2</sup> *Food and the Family*. By V. H. Mottram, M.A. London: Nisbet and Co., Ltd., 1925. (Cr. 8vo, pp. xiii + 240; 3 figures. 5s. net.)

<sup>3</sup> *Röntgen Diagnosis and Therapy*. By Arthur C. Christie, M.D., M.S., F.A.C.P. London: J. B. Lippincott Company, 1925. (Med. 8vo, pp. vi + 320; 180 figures. 25s. net.)

indicated. The short chapter on therapy, without going into any detail, is sufficient for its purpose. In the preface the author states that his aim has been to furnish to the student and practitioner a concise account of the essentials of radiology and a practical guide to the subject. He also lays great stress upon the fact that the foundation for success as a radiologist is "good technical work"; without this no x-ray work can be really successful, although of course it does not follow that one who relies upon this alone is a good radiologist. We can confidently recommend this book to the beginner, and also to the general practitioner who wishes to have some knowledge of the present position of x-ray diagnosis.

We received some time ago a copy of *Chinese Grammar Self-Taught*,<sup>8</sup> by Dr. JOHN DARROCH, and it may be worth while to give a short account of it even at this late date. The author has endeavoured to exhibit the structure of this picture language in terms of the grammar of European countries. For this reason the book should be useful to those who may be led to practise in China. It should be entertaining, also, to others, though they may not feel called upon to study the oldest Chinese medical work containing the plain questions of the Yellow Emperor Su Wen, 2698-2598 B.C.; nor to investigate the actions of the 1,892 drugs contained in the Herbal of Li Shih-chên, which included certain remedies called "sovereign," as certain others were formerly called in this country. The development of the simple pictures of objects into the elaborate modern Chinese characters is set forth interestingly by Dr. Darroch; and the beginner will marvel at the number of those characters required to express a simple short sentence.

Although Mr. COMYNS BERKELEY's *Handbook of Midwifery for Midwives, Maternity Nurses, and Obstetric Dressers* has not yet attained its majority, yet a sixth edition<sup>9</sup> has been called for. This little book is so well known that nothing need be said specially to commend it. The most important change in this edition is the recasting of the chapters on artificial feeding and on the care of premature infants, which have been altered in accordance with the most modern views. The book is of a very convenient size and forms a thoroughly sound guide for all those for whom it is designed.

EDELMANN's *Text-book of Meat Hygiene* has now reached a fifth edition,<sup>10</sup> which has been prepared by Dr. MOHLER, Chief of the United States Bureau of Animal Industry, and Dr. EICHORN, Director of the Veterinary Department in the Lederle Antitoxin Laboratories. The book is based on the regulations governing meat inspection in the United States. An account is given of the methods of laboratory examination for detection of harmful preservatives and adulterants. Chapters are devoted to the examination of prepared and preserved meat, to meat poisoning, to the preparation and control of meat-food products, and to their chemical analysis. Abattoirs and stockyards, including those at Chicago, are described. The illustrations are well done and the volume gives a full account of the meat industry as developed in the United States.

<sup>8</sup> *Chinese Grammar Self-Taught*. By Dr. John Darroch, Litt.D., O.B.E. Marlborough's (Cr. 8vo, pp. 15).

<sup>9</sup> *A Handbook of Midwifery, Maternity Nurses, and Obstetric Dressers*. By Mr. Comyns Berkeley, M.C., M.D. (Camb.). London and New York: Cassell & Co. (1924, 8vo, pp. xii + 578; 74 figures, 8s. net.)

<sup>10</sup> *Text-book of Meat Hygiene*. By Richard Edelman, Ph.D. Fifth edition revised by John R. Mohler, A.M., V.M.D., and Adolph Eichhorn, D.V.S. London: J. and A. Churchill. 1925. (Med. 8vo, pp. vi + 478; 161 figures, 25s. net.)

## MEDICAL AND SURGICAL APPLIANCES.

### An Invalid Appliance.

SIR ROBERT C. BROWN (Preston) writes: About a month ago, while opening and closing a drawer in my dining-room sideboard, the idea occurred to me that much benefit and comfort might be obtained by sick persons and chronic invalids by adapting a similar sliding arrangement to what is known as "the bed-pan." The provision necessary for carrying out what I suggest is: (1) A hole of sufficient size and suitable shape in the mattress and wire sheeting on which it lies. (2) A sliding shelf to which the bed-pan is affixed. (3) A frame standing on four legs, like an ordinary chair, in which the shelf can be applied or withdrawn. At the end of each leg is a castor or small swivelled wheel, and this shelf containing the bed-pan from the hole in the mattress and wire sheet. (4) A simple mechanical arrangement working with a handle and screw for placing in position from below the cover for the hole in the mattress and wire sheet, and taking care that it fits accurately so that the patient does not experience any edge, ridges, or projections.

## INTER-STATE POST-GRADUATE ASSEMBLY OF AMERICA.

### THE ULSTER VISIT.

At page 1150 last week we gave a brief account of some of the proceedings in Northern Ireland. About four hundred of the visitors arrived in Belfast on the evening of June 11th: extensive arrangements had been made to give them a hearty reception and a warm welcome. Some of the wives of the medical men had made preparations for the ladies of the party to enable them to see the town, and a room was kindly kept by the Central Y.M.C.A. as a rendezvous. Excursions left each day for some of the more distant sights: Portrush and the Giant's Causeway were favourite selections. On the morning of June 13th the second half arrived, and the first left.

Professor Lindsay, chairman of the board of management of the Royal Victoria Hospital, received each section in the King Edward Hall and offered them a hearty welcome to hospitals in the city: they looked upon it, he said, as a compliment to the city and to the medical school, and hoped their all too brief stay would be to them a source of pleasure and satisfaction, and leave behind agreeable and lasting memories. Ulster had many ties with the United States and Canada; it had given of its best to them: ten of their Presidents were said to be of Ulster lineage, and one of the most illustrious Governor-Generals of Canada, the late Lord Dufferin, came from their midst. The visitors came, not as strangers, but as friends and comrades united by many ties, influenced by common ideals, and engaged in the common work of endeavouring to alleviate human suffering: their visit was one of the many signs that science was becoming international and knew no race or creed. Professor Lindsay then gave a brief account of the hospitals in Belfast, and drew attention to the special features of the Royal Victoria Hospital, its plenum system of ventilation and its organization; as regards the former, after twenty-two years' experience they were pleased with it as an unqualified success, both as to purity of air and smoothness of working. The chairman of the medical staff (Mr. Mitchell) joined in offering their warmest welcome.

The visitors then attended the pathological, electrocardiograph, blood, clinical, laboratory, bacteriological, and radiological demonstrations, the operations and the lectures that had been arranged for the forenoons, both in the Royal Victoria Hospital and also in the Mater Infirmary Hospital, the special hospitals, and the Municipal Fever Hospital, the Purdysburn Villa Colony, and Graymount Hospital for Tubercular Children and Open Air School. An excellent little booklet had been prepared so that the visitor could tell at once what was on, and the actual operation was posted up on the notice board. It would be impossible to give all the items of the operations, demonstrations, and lectures, as nearly every member of the various staffs did something, and the visitors had an opportunity of seeing the full working of the clinical side of the medical school, which is one of the largest in the United Kingdom.

The Lord Mayor of Belfast, Sir William Turner, received the members of the Assembly and their friends in the City Hall on the afternoon of June 12th, and offered them the welcome of the city, with wishes for a pleasant and happy stay. On Saturday afternoon, Lord and Lady Londonderry delightfully entertained the members of the Assembly at a garden party at their beautiful residence, Mountstewart, The Ards, co. Down, where the combination of fine weather, charming gardens with a perfect blaze of colour, old woods, and rare trees, the noble mansion, and the near proximity of isle-studded Strangford Lough, formed a scene that one may be sure will not soon be forgotten by the guests. On Monday afternoon, June 15th, the members of the Assembly were entertained by the Prime Minister of Northern Ireland, Sir James Craig, at a garden party at his residence, Stormont Castle. Unfortunately, Sir James and Lady

Craig were detained in London; but everything joined in carrying out the kind wishes of the host and hostess for a beautiful and pleasant afternoon in the entertainment of their guests.

#### VISIT TO MANCHESTER.

Some of the members of the Assembly who had been in London the previous week visited Manchester on June 8th-10th. About 160 were accommodated in Manchester itself, and another 100 who stayed in Southport were attached to the Manchester group. The mornings of the three days were devoted to hospital visits, the afternoons of Monday and Tuesday to series of short lectures at the University and the Royal Infirmary respectively. The lectures were given as follows:

Mr. G. Jefferson: The diagnosis of Jacksonian epilepsy. Professor G. R. Murray: Success and failure in organotherapy. Professor E. D. Telford: Formation of bone in soft parts. Professor J. S. B. Stopford: Some investigations of sensation. Sir William Milligan: Infective labyrinthitis; its role in the production of otitic meningitis and its surgical treatment. Dr. J. C. Bramwell: Arterial insufficiency. Professor W. W. C. Topley: The experimental study of epidemics. Professor A. Donald: Gynaecology in Manchester. Professor A. H. Burgess: Symptomless haematuria. Mr. Harry Platt: The surgical treatment of arthritis deformans.

Messages of welcome were given by Mr. Fiddes, the Pro-Vice-Chancellor of the University, and by Mr. Goldschmidt, the chairman of the board of the Royal Infirmary. Most of the hospitals, general and special, were open to the visitors, and among other institutions Mousall Fever Hospital and the group of tuberculosis sanatoriums and colonies in Cheshire attracted some of the visitors. The Royal Infirmary, owing to its size and modern construction, naturally received much attention. The Lord Mayor, who had returned from the Continent with this special object, gave a soirée at the Town Hall on Tuesday evening. On Tuesday and Wednesday the American visitors were entertained to lunch at the Midland Hotel by the Manchester Branch of the Anglo-American Society, and by the staffs of the Manchester and Salford Hospitals respectively. After the latter lunch Dr. Mayo laid on the Manchester war monument a wreath given by the Assembly. For the non-medical members of the party a trip on the Ship Canal and visits to the Rylands Library, Chetham's Hospital, Haworth's cotton mill, and the Royal Exchange at the time of "high change" were arranged.

The visitors expressed themselves well pleased with their stay in Manchester. The arrangements for their welcome were in the hands of a reception committee whose chairman was Sir William Milligan, and honorary secretary Dr. E. Bosdin Leech.

#### VISIT TO GLASGOW.

Under the auspices of the Glasgow Post-Graduate Medical Association preparations had been in progress for some time past for this noteworthy event. A period of only two days was allotted to Glasgow in the very comprehensive tour which has been undertaken by this large body of American and Canadian medical men, and for these days a full programme had been arranged.

The forenoon and afternoon of June 16th were occupied with clinics and demonstrations at the various hospitals and infirmaries, both general and special, throughout the city, and these opportunities for clinical work were largely taken advantage of by the transatlantic visitors. In the evening they were the guests of the University of Glasgow at a conversation in the Bute Hall, where they were received by Principal Sir Donald MacAlister, Bt., and Lady MacAlister. A large company, representative of town and gown, assembled to take part in welcoming the visitors from overseas. In the course of the evening Sir Donald MacAlister, in the name of his colleagues in the medical school of Glasgow, bade them welcome to Scottish soil and to Scottish hearts, and, in the name of the General Medical Council, of which he has been president for over twenty years, assured them of the hearty and brotherly welcome of the profession at large. He referred to the leader of the Assembly, Dr. Charles H. Mayo, as the leader of this new crusade of Knights Hospitaliers, and informed him that the motto of the Mayos in Scotland was *E cruce salus*. Sir Donald referred to the many historic

names which appeared in the list of the University's famous teachers of medicine and surgery, from Cullen and Black, Smellie and Hunter, down to Lord Lister, who had there wrought out the principles and practice of antiseptic surgery, so brilliantly applied in the relief of suffering by American surgeons. In his reply, Dr. Mayo gracefully acknowledged how much the science of medicine owed to the University of Glasgow for its modern development, and he expressed on behalf of the visitors their appreciation of the very comprehensive and varied clinical fare provided that day by the Glasgow Medical School. He said that when they returned to America they proposed to report to their associations, and with the scientific information they would circulate they would broadcast also their sense of the friendship which had been shown to them in this country. Thereafter, in the name of his colleagues, he bestowed honorary membership of the Inter-State Post-Graduate Assembly upon Principal Sir Donald MacAlister, Mr. Archibald Young, Regius Professor of Surgery in the University of Glasgow, and Dr. James Carslaw, Secretary of the Glasgow Post-Graduate Medical Association. Throughout the evening a musical programme was submitted, and was heartily appreciated.

On June 17th the visitors engaged in a tour to Loch Lomond and the Trossachs; on their return they attended a civic reception in the City Chambers, where they were received by Lord Provost M. W. Montgomery and Mrs. Montgomery, and the magistrates. In his speech of welcome the Lord Provost referred to the record of the City and University of Glasgow in medical research and in the advancement of medicine and surgery, and to the mutual benefit which must result from such international meetings in medical matters, and also to the good influence which such gatherings must exert in the development of mutual understanding and in strengthening the ties of Anglo-American friendship. Dr. Mayo, in replying, expressed their appreciation of the hearty welcome which had been extended to his party in Glasgow, a city which had powerful attractions for medical men as a shrine of the great Lister, and as a centre of modern development in medicine and surgery. Not only had they derived great scientific advantage from their visit to this country, but he believed that their visit would do a great deal to maintain the growing harmony between the two great English-speaking peoples. Dr. William B. Peck also replied on behalf of the guests, and humorously remarked that if the doctors they had left behind in America realized what they had missed there would not be sufficient ships on the Atlantic to bring the next invasion of the members of their association. The formal reception was followed by dancing in the banquet hall, and a concert in the council chamber. The company present numbered about 1,000, and included many of Glasgow's prominent citizens.

#### VISIT TO EDINBURGH.

The members of the Assembly, after a visit to various schools in the English provinces, to Dublin and Belfast, and to Glasgow, reached Edinburgh on June 18th.

About 400 members of the party assembled in the McEwan Hall, where the degree of LL.D. was conferred upon Dr. Charles Mayo. The McEwan Hall was well filled by members of the public and by students as well as by the party of American visitors. Sir Alfred Ewing, Vice-Chancellor of the University, who presided, said it was a pleasant duty for him to express, on behalf of the University, a welcome to them as representatives of the great medical association, the Inter-State Post-Graduate Assembly of America. He hoped they would feel in a special sense at home in Edinburgh. They all knew that the heart and kernel of any well regulated home was the nursery, and where was the nursery of medicine to be found if not in Edinburgh? Edinburgh was peopled by the shades of those who had made history in medicine. They had come to the medical school here as to a shrine, but not simply as to a shrine hallowed by noble traditions and memories of the immortal past, but he hoped and believed that they might come to it as to a fountain of living water from which there continued to flow a stream of gathered knowledge and fresh discovery. Their visit, he imagined, was mainly for

the purpose of meeting her teachers face to face and in order to profit by the stimulus that came from contact and from study not only of methods but of men. They in Scotland admired the splendid share taken by the United States in the development of the science of medicine and surgery. They would find all doors open in Edinburgh and would receive a fitting welcome in the inner holies of this Mecca of medicine. Professor James Mackintosh, K.C., Dean of the Faculty of Law, in presenting Dr. Mayo for the honorary degree of LL.D., said that the names of Dr. Charles Mayo and of his brother William were revered throughout the surgical world as those of the joint founders and directors of the famous Mayo Clinic at Rochester, an institution which for some years past had occupied a foremost place as a post-graduate school of surgery. The brothers Mayo, with characteristic generosity and foresight, had benefited and endowed several research scholarships. Dr. Mayo was known all over the world as a leading authority on the pathology and treatment of diseases of the thyroid gland. To his wide knowledge and vast experience he added the sound judgement and wise discretion that gave his opinions exceptional weight with his professional brethren, and when the United States entered the war he and his brother had held alternately the post of Chief Consultant for Surgical Services in the Army Medical Department. The Dean then presented Dr. Mayo for the degree of LL.D., which was conferred by the Vice-Chancellor. Dr. Mayo, in his reply, said that words crowded his mind in a disorderly way due to the emotion of the occasion. Edinburgh University was fortunate in being located in one of the few beautiful cities of the world. He appreciated highly the honour which this institution had now given him in this honorary degree, and he received it in the sense that it was presented to the medical profession of America through the fortunate circumstance that he was there as the representative of the Inter-State Assembly, which not only took in the United States but had members in each province of Canada. He would point out that over 500 doctors from America were now in Edinburgh and that these represented every State in the Union. They would go back taking with them the memory of all the kind and courteous treatment they had received and of the efforts on the part, not only of men of the medical profession and of scientific men, but of the best men in the British Isles, who had looked after them in every way; and they would take with them a kindly feeling for the old country from which they sprung. For the preservation of civilization a closer harmony was necessary, and the two great English-speaking peoples should come closer and closer together as time went on.

After the reception by the Vice-Chancellor and graduation ceremony the American doctors adjourned to the neighbouring Royal Infirmary, where the whole staff took part in a series of clinics, operations, and demonstrations on various departments of surgery, medicine, gynaecology, ear, nose and throat diseases, and eye diseases. After lunch three large meetings were held in the Large Surgical Theatre, East Medical Theatre, and West Medical Theatre, at each of which a series of clinics lasting about fifteen or twenty minutes were delivered on various special subjects. On Thursday evening a reception was held in the grounds of Inverleith House, which had been lent to the Town Council for the purpose by Professor Wright Smith, Regius Keeper of the Royal Botanic Gardens. Lord Provost Sir William L. Sleight and Lady Sleight, supported by the magistrates and town councillors, received the guests. The Lord Provost, in a speech of welcome to the gathering, said that the City Fathers were proud of the Edinburgh Medical School and its eminent surgeons and physicians, whose reputation he thought was second to none and whose skill and ability had done much for suffering humanity; they were glad that the Assembly had included Edinburgh in their tour and that they were having a busy time at the clinics and demonstrations organized for them. The reception, which was held in the open air, was fortunately favoured by perfect weather, and the beauties of the Botanic Garden appreciated by the American visitors.

On Friday, June 19th, two excellent museums in surgery, pathology, and bacteriology had been organized—one in

the pathological department of the Royal Infirmary, and another, which dealt mainly with bacteriology, in the pathological department of the University. A series of medical and surgical clinics in the operating theatres and wards of the Royal Infirmary and of the Sick Children's Hospital, similar to those of Thursday, was held in the forenoon of Friday, and in the afternoon two series of short clinics lasting fifteen to twenty minutes each were held in the Large Surgical Theatre and in the West Medical Theatre. The attendance of the visitors at the clinics both on Thursday and Friday was maintained in very nearly full numbers. Subsequent to the afternoon clinics, the party of visitors were conveyed to Holyrood Palace, where they were met by a party of ladies, the wives of the medical teachers. About 300 visitors passed through the palace in groups of about forty, being guided over the State and historical apartments. Tea was served in the grounds behind the palace. The majority of the American doctors left for the South on Saturday morning, en route for Paris.

### VISIT TO NEWCASTLE-ON-TYNE.

A party of American medical visitors, numbering about eighty, visited Newcastle-on-Tyne on Saturday, June 20th, on their way back from Edinburgh. They were met at the Central Station and conducted in parties to the Cripples' Home at Gosforth, the Princess Mary Maternity Hospital, and the Children's Hospital, where various methods of treatment were demonstrated by members of the staffs of the institutions.

The visitors next attended a reception in the library of the Royal Victoria Infirmary, where they were cordially welcomed by Lord Armstrong, chairman of the house committee, with whom were Sir Thomas Oliver, Dr. Beattie, Dr. A. M. Martin, chairman of the honorary medical and surgical staff, and Dr. R. A. Bolam. In the course of his short address Lord Armstrong spoke of the debt owed by the medical profession to the great post-graduate clinic which their visitors had so successfully established, and with which their leader, Dr. Charles Mayo, was so honourably and so inseparably connected as its president. He then gave some account of the Infirmary and its work. Last year, he said, they treated more patients and performed more operations than any other hospital in England except the London Hospital. On behalf of the medical staff Dr. Martin added a few words of welcome. Immediately after the reception the visitors again separated into parties for the purpose of attending demonstrations in the wards, operating theatres, lecture theatre, and pathological and electrical departments. An exhibition of pathological specimens from the College of Medicine had been arranged for their benefit in the Board Room, and some rare books were on view in the library. The anatomy department and pathological museum of the College of Medicine were also open for inspection, and opportunities were given to visit the War Pensions Hospital adjoining the Royal Infirmary.

At 1 o'clock the visitors were entertained to luncheon at the Grand Assembly Rooms by the Lord Mayor of Newcastle, Alderman Walter Lee, on behalf of the city council. The Lord Mayor, in proposing the toast of "Our Distinguished Guests," said that the people of Newcastle were glad that this ancient city had been included in the visit of the American physicians. Dr. Charles Mayo, in reply, thanked the Lord Mayor and corporation for their hospitality. Referring to Lord Armstrong's generous gift of £100,000 to the Royal Infirmary, he announced amidst loud applause that in recognition of the great work they had done for medicine it was resolved to make Lord Armstrong, Professor Rutherford Morison, Dr. Beattie, Dr. Martin, and Mr. Grey Turner, honorary members of the American Inter-State Post-Graduate Assembly. The health of the Lord Mayor was proposed by Sir Thomas Oliver, who expressed the thanks of all present for the civic hospitality.

After luncheon the visitors were taken by motor coaches to Durham, and visited the cathedral and castle. They were entertained to tea at the Deanery by Bishop Welldon, Dean of Durham, and returned to Newcastle in time to catch a special train for London.

SATURDAY, JUNE 27TH, 1925.

## THE MEDICAL WITNESS.

It is no exaggeration to say that of the expert evidence in courts of law the larger part is given by members of the medical profession. It therefore behoves all medical men to acquire a sound knowledge as to how best they can prepare themselves for the task. The British Medical Association Lecture recently given by Mr. H. H. Joy, K.C., to the South Staffordshire Division, published this week (p. 1159), supplies much useful practical information and embodies many shrewd pieces of advice. The lack of knowledge of a few simple precepts may easily turn a medical man's appearance in the witness-box into an uncomfortable ordeal. Mr. Joy warns the medical witness against some of the common mistakes he is apt to make, and tells him in plain words, reinforced by homely illustrations, how he can best avoid those traps into which the unwary fall.

Mr. Joy refers—all too briefly, we think—to the question of joint conferences between medical witnesses on both sides before the hearing of a case. In this connexion we may recall that in 1923 the Representative Body of the British Medical Association resolved "that it is desirable that medical men who may be called as witnesses in legal cases (especially under the Workmen's Compensation Act) should consult with each other before the case is heard so that they may if possible agree upon the facts." Upon this resolution the Council of the Association reported that, as this policy had been laid down by the Association as far back as 1905, no further action was necessary beyond a reminder to the Divisions. Mr. Joy favours these joint conferences, but considers they should be held "without prejudice." Some time ago an interesting correspondence on the subject arose in our columns, and the late Sir Clifford Allbutt, in a letter published on December 22nd, 1922, gave an account of the excellent results obtained from the adoption, in his early days in Leeds, of the method of joint conferences, "to avoid the setting up of medical men as fighting-cocks one against another." The method, he said, was bitterly opposed by the lawyers at first, but gradually the best legal firms and the leading counsel approved and applauded it, for the evidence was immensely improved in both quality and consistency, new facts or new interpretations came out, and doctors of less experience were not sorry to accept a more adequate diagnosis or partial modifications. We have not only Sir Clifford Allbutt's word that these excellent results invariably flowed from joint conferences: the late Mr. Justice Stephen, in a case in which Sir Clifford Allbutt was a witness, paid a weighty tribute to the medical testimony given in Leeds—"the only town where he never heard those unseemly disputes between the legal and medical professions which occurred at other places." But, as Mr. Joy points out, even the method of joint conferences is not without danger. For instance, if one doctor should be examined or cross-examined as to what the doctor to be called by the other side said at the joint conference, his answers might involve personal conflicts of recollection. To avoid such un-

pleasantness there ought to be a distinct stipulation that such joint conferences be held "without prejudice," so that there can be no examination or cross-examination with regard to it of the medical men on either side.

To those who assert that the fact that doctors are willing to go into the witness-box and give diametrically opposed statements of opinion somewhat minimizes the value of such evidence, it may be retorted that even judges differ in their opinions on the law, and that judgements in lower courts are often reversed in the court above. Differences of opinion honestly held there will always be. Because one doctor holds a contrary opinion to that held by another it ought not to be inferred that one of them is not to be believed on his oath. Yet this was the very fallacy that Lord Justice Scrutton exposed in his judgement in the Harnett case, when he characterized the direction of Mr. Justice Lush to the jury, "Which do you believe?" as "unfortunate," adding, "The truth is in these mental cases you may believe both." The real question for the jury was: "Do you believe those witnesses who depose to facts which are strong evidence of instability of mind, and what conclusion do you draw from them?" We think Lord Justice Scrutton's comment applies to almost all cases where medical witnesses are called by both sides.

We believe Mr. Joy's advice to be sound when he recommends medical witnesses to attend the conference always held between counsel and the professional and lay clients before the hearing of a case. It is of cardinal importance that counsel should grasp clearly the bearings of the case in its medical aspects, and the medical witness ought not to leave counsel to mere second-hand knowledge conveyed through possibly inadequate instructions from professional and lay clients. Then, further, the medical witness ready to give evidence as to his opinion upon a fact may be surprised to learn while waiting that this fact is inaccurate; and here again it is obvious that the medical witness should at once apprise his counsel of the effect of the new or altered fact upon the evidence he is about to give.

The use of technical terms is sometimes inevitable, and there are cases in which the judge, counsel, and jury must be educated by the medical witness as to the meaning of an abstruse technicality—and this is especially so where there is a fine issue and there happens to be no simpler word in which a certain condition may be accurately described. Subject to this, we sympathize with Mr. Joy when he says that "scientific evidence should be as unscientific as possible when given in court," and (we take the liberty to add) particularly where such knowledge has to be conveyed to the understanding of the average common jury. Mr. Joy's illustration of the futility of the use of technical language where simple words would suffice is a familiar one to medical men—a medical witness's description in pathological terms of a lesion over the orbit, and the judge's comment, "If you mean a black eye why don't you say so?"

The medical profession has always urged that the privilege of non-disclosure should be accorded to medical witnesses where communications of a professional character are concerned. Mr. Joy dismisses this claim as an impossible one—first, because if it were conceded it would conflict with statute law (the Notification of Diseases Act and the Notification of Births Act); and secondly, because in civil and criminal proceedings the ends of justice would be defeated if doctors were allowed to decline to give

evidence of the facts which had become known to them. Lord Justice Atkin, we are glad to observe, was not quite so dogmatic when he recently said that no doubt the law would so remain until some doctor—"should he say some fanatical doctor?"—preferred prison to violation of the confidence reposed in him by his patient. Lord Justice Atkin suggested that the question might then arise whether the conflicting claims of public health and public justice could not be reconciled by something less than a complete obligation on the part of the doctor to make disclosure when called upon to do so. Mr. Joy holds that an absolute privilege not to disclose cannot be accorded the doctor, but we venture to hope, with Lord Justice Atkin, that a qualified privilege is within the realms of possibility. For we presume him to have meant that upon the hypothesis of a "fanatical doctor" electing to go to prison rather than to disclose, the Legislature or the Bench might extend the privilege, already accorded to confidential communications between solicitor and client, not to all, but to a certain class or classes of communications between doctor and patient. At present the medical witness confines himself to a refusal to disclose such confidence until instructed by the judge to make disclosure.

Perhaps the most vital piece of advice contained in Mr. Joy's lecture is his warning to the medical witness against what he picturesquely terms "unconscious partisanship," which, he says, accounts for much of the differences of opinion expressed by the doctors on either side in a case. Counsel is a partisan. He identifies himself with his client's legal fortunes. He is out to win his case by bringing every scrap of evidence and every subtlety of argument to bear upon the minds of the judge and jury to secure a verdict and judgement from them favourable to his client. That, the Bar holds, is what he is briefed for—what is expected of him by judge and jury alike. But this same partisan attitude, which is the essence of successful advocacy, ought to be strenuously avoided by the medical witness. It is true that the mere fact that he is giving evidence for one side tends to identify the medical witness with the legal fortunes of that side, and it is no doubt extremely difficult to avoid the appearance of partisanship, in a mild form at any rate. But if the medical witness remembers that the judge and jury look to him, as a member of a profession possessing high traditions of honour and of scrupulous fairness, to give them a reasonable and impartial statement which will serve to guide them to a right decision, he will give due weight in whatever he says, not merely to the facts deposed to by the other witnesses on his own side, but also to the facts deposed to by the witnesses on the opposing side. This is the type of medical witness the cross-examiner makes very little, if any, headway against. The medical witness, to use a military phrase, has dug himself well in during his examination-in-chief—has not overstated his case, and has made reasonable allowances to the other side already—and so he is now the better able to resist the onslaughts of the cross-examiner. There are cross-examiners and cross-examiners. The most dangerous type is the counsel who puts a question in a form which makes it impossible of truthful answer Yes or No. Very often the judge leaves the task of objection to counsel on the side by which the witness has been called. But the counsel is not always sufficiently alert to protect the witness from questions couched in ambiguous form. In this event the witness is left to his own resources—a layman unskilled in the

field of dialectics pitted against counsel with whom dialectic skill is part of his stock-in-trade. The medical witness would do well to read the Lord Chief Justice's *obiter dicta* on questions put in cross-examination, which will be found in his judgement in *Rex v. Baldwin* (*Times*, March 17th, 1925). In both civil and criminal cases, he said, questions are often asked which are really of the nature of an invitation to an argument—for example, "Is your evidence to be taken as suggesting that . . . ?" The Lord Chief Justice said the prudent witness would answer that he was there not to make suggestions, but to answer relevant questions, and that the conclusions to be drawn from his evidence were for others. As a matter of fact, such a reply it would be almost impossible for any witness to think of making. The Lord Chief Justice himself said that such an answer required a good deal of sense, self-restraint, and experience, but—what is more—it might prejudice the witness in the eyes of the jury. If a medical witness does meet this mischievous type of cross-examination he must above all keep cool, and before answering perhaps an inquiring movement on his part towards the judge may cause help to come from that direction. We say "keep cool," because it is just at the stage when questions are put in a most mischievous form, tending to confuse or aggravate the witness, that tempers become strained. It is well to remember that upon onlookers, as the judge and jury are, exhibitions of lack of self-control have a damaging effect. A witness who loses his temper usually loses his side's case into the bargain. It is, at any rate, a walk-over for counsel so far as that witness is concerned. Counsel's ebullitions—if he is a good advocate—are but simulated for the occasion, and do not involve the slightest loss of self-control.

Mr. Joy's lecture will have served its purpose if it arouses fresh interest and evokes wide discussion of what we consider a much neglected side of the life of the medical man, yet, at the same time, a side which is growing in importance daily—preparation for appearance as a medical witness.

### MEDICAL RECIPROCITY WITH ITALY.

Now that a fresh agreement has been signed with Italy, under the terms of which medical practitioners possessing degrees from the Royal Italian Universities may register in the Foreign List of the *Medical Register* of the United Kingdom, thereby obtaining full privileges of practice in Great Britain and Ireland, and British practitioners may obtain full freedom to practise in Italy, it may be interesting to record the history of this arrangement.

In 1892 the Privy Council forwarded a communication enclosing a copy of a "projet de loi" in regard to medical practice in France, together with a report in which it was recommended to the French Senate that after an interval of a year from the passing of the Act no person should be entitled to practise medicine in France except those who held the Government diploma of M.D. The General Medical Council thereupon drew up a statement of the terms on which foreign medical men were admitted to practise in this country, and this was forwarded to the proper Ministerial authority in each of the principal foreign countries in Europe, in order that they might have the conditions before them.

A reply was received from Italy that under the law then in force foreign doctors and surgeons might exercise their profession in Italy provided they were

furnished with a professional qualification (*abilitazione*) granted by one of the Royal Universities; and it was added that foreign doctors and surgeons could practise, without complying with this condition, when they were summoned from outside the kingdom to attend special cases.

Nothing further was heard of the matter until in 1897 the General Medical Council was informed by a private correspondent that a law was about to be introduced into the Italian Parliament which was of vital importance to all British medical men actually resident and practising in Italy, particularly if the law should be made retrospective, because they would no longer be able to carry on their practice in that country. The Council thereupon communicated with the Privy Council, and was informed that there was no intention at that time on the part of the Italian Government to modify the existing laws. Shortly afterwards, however, it appeared that Italy was contemplating a change in the law which would adversely affect British practitioners. In 1899 the Italian Ambassador asked if Italian physicians in England could practise "in the foreign colonies" of this country; and, if they could not, whether the Government would grant special permission to Italian practitioners if similar facilities were granted to English practitioners living in Italy. The matter was referred to the Council's legal advisers, who gave an opinion that the only alternative to refusing permission to practise, excepting under Section 6 of the Medical Act, 1859, which allowed a foreign practitioner legally qualified in his own country to act as resident medical officer in a hospital exclusively for foreigners, was to extend Part II of the Medical Act, 1886, to the country concerned, which would give full privileges of practice to all those who complied with the conditions laid down.

Further correspondence took place, with the result that in 1901 Part II of the Medical Act, 1886, was extended to Italy, and Italian practitioners were thereby given full freedom of practice in the United Kingdom. Italy, however, did not adopt full reciprocity, and British practitioners were entitled only to practise in that country amongst their own countrymen. It was thought advisable to accept this one-sided arrangement, which was strongly advocated by British practitioners in Italy at that time, because otherwise the British practitioners already in Italy would have lost their practices, and no others would have been able to enter that country.

In 1910 a new law was passed in Italy, under which foreign practitioners whose own countries granted reciprocity of practice to Italy were favourably affected, since, instead of the limited right of practising only among foreigners, they thenceforth enjoyed unrestricted freedom of practice. It was stated that, as matters then stood, this concession benefited British practitioners only, Great Britain being the only country that granted reciprocity to Italy.

This satisfactory condition of affairs continued until 1923, when the General Medical Council was supplied with a copy of the Royal Italian Decree of March 25th, 1923, which was to the following effect: "Italian subjects and foreigners who have duly obtained a professional diploma in an institute of a foreign State can also be inscribed, when such State has come to a special agreement with the Italian Government on the basis of absolute reciprocity of treatment for Italian subjects holding Italian diplomas." This correspondence came through the Ministry of Health, which was informed that, as complete reciprocity in

regard to medical practice was established with Italy in March, 1901, and confirmed by Italian legislation in June, 1910; it did not appear that the new regulations affected Great Britain. A copy of the correspondence was forwarded to the Privy Council for its information.

The General Medical Council was informed at this time that a practitioner whose name was on the *Medical Register* had been refused leave to practise in Italy, and the Privy Council was thereupon asked that His Majesty's Ambassador at Rome might be requested to make urgent representations on his behalf. Further correspondence ensued, and the British Ambassador wrote in December, 1923, that the "special agreement" between the two Governments had been rescinded by the recent decree, in so far as fresh applications from British doctors to practise in Italy were concerned, and that it would be necessary to come to a fresh "special agreement" before reciprocity was again on a satisfactory basis. The practitioner in question, having been informed by the Italian Consul that he would be able to practise in Italy, and having thus been placed in a serious position, was as a special case allowed to register in Italy, but the main question still remained unsettled.

Much correspondence on both sides followed during 1924, and for a long time it was impossible to get the Italian authorities to take any definite action. It was not until December 30th last that the Privy Council was able to transmit a draft of an agreement between Italy and Great Britain to regulate the matter. This draft required some amendment in regard to technicalities, but it was promptly returned by the General Medical Council to the Privy Council. At the end of January, 1925, the Italian authorities suggested certain further amendments, which were immediately accepted; but, notwithstanding the efforts of the General Medical Council, the Privy Council, and the British Ambassador, it was not until May 21st, 1925, that the agreement was finally signed. Thus for some two years, although Italian doctors were freely allowed to register in this country, British practitioners were not granted similar privileges in Italy. Even now the Italian authorities do not seem to have settled what their requirements will be, and the Italian Consul states that it appears that the agreement cannot come into force until it is duly ratified or approved by the Italian Parliament. He does not seem to be in a position to give definite information, but every effort is being made, with the cordial assistance of the Privy Council, to have the difficulties cleared up at the earliest possible moment. All those who desire information should write to the Royal Italian Consul, 144, Queen Victoria Street, London, E.C.4, asking to be informed of the requirements as soon as they are finally laid down. Under the old arrangement an applicant had to produce: (1) his diploma at the town hall of the city in Italy in which he desired to practise; (2) a certificate of medical registration in Great Britain up to date; (3) his birth certificate; (4) a certificate of immunity from any charge, offence, or conviction (which could be obtained from the chief constable or town clerk of the place in which he resided); (5) a certificate attesting that he is in full possession of all rights pertaining to a citizen or member of society (which also could be issued by the town clerk). The diploma and certificates had to be produced at the Consulate for legalization and translation into Italian, and the fee charged was about £12 5s. It is probable that somewhat similar conditions will be laid down for the future.

## INCOME TAX ALLOWANCE FOR DEPRECIATION.

THE Chancellor of the Exchequer has agreed to the insertion in the Finance Bill for this year of a clause put forward by Dr. F. E. Fremantle which is of some importance to medical practitioners. The effect of the clause will be to remove the distinction that has hitherto obtained between traders and professional men with regard to an allowance year by year for the depreciation of plant and machinery used in the earning of their income. Traders have been entitled to such an allowance, but the use of "plant and machinery" by professional men is comparatively recent, and the distinction referred to was evidently the accidental result of the circumstances obtaining when the Income Tax Code was enacted. Arguments in favour of its abolition were put before the Royal Commission on the Income Tax by witnesses representing the British Medical Association, and that Commission reported in favour of the change now to be effected. It may be convenient to indicate here the nature and results of this change.

It is obvious that during his professional career a medical practitioner must normally incur considerable expense in maintaining his motor car equipment. Running expenses—such as the cost of petrol, tyres, oil, and the like—recur frequently, and the proper mode of dealing with them in calculating professional profits is clearly to regard them as expenses chargeable to the year in which they were in fact incurred. But besides running costs, there is the comparatively rare and heavy expense of substituting a new car for one which has become unsuitable for professional use. An accountant, in preparing accounts for a business in which a car—for example, a delivery van—is used, would very properly regard it as necessary to set aside some portion of the profits each year to provide against the expense of replacing the car at some future date. Actually the sum estimated according to the probable life of the car might not be taken out of the business, but the appropriate amount would be charged against the year's profits, so that the correct net balance only would appear as the true amount of the profits made. Substantially—minor differences will be explained later—this principle is accepted by the Income Tax Acts as applied to commercial profits, but hitherto professional profits have been dealt with differently; no anticipatory depreciation allowance has been given, but in lieu of that the professional man has been entitled to treat as an expense of his practice the actual net cost of replacing his car with one of similar grade. This method is open to two main objections: first, that the allowance is not received soon enough, and secondly, that it is insufficient in amount. So far as the question of time is concerned, the expense is originally incurred when the first car is bought, whereas no allowance is received until that car is disposed of and a second one bought to replace it. Even then, the three years' average adds a further period of postponement to the allowance. For instance, suppose the first car to have been purchased in 1920 and the second in 1926, no allowance at all would be received until tax became payable in January, 1928, and then the tax would be affected only by one-third of the sum charged against the 1926 profits owing to the fact that the 1927-28 assessment would be based on the profits of the three years to December 31st, 1926; not until 1930 would the benefit of the full allowance have been received. Secondly, the allowance was insufficient, partly, because the practitioner's retirement or death would

normally leave him in the position of having a car on which depreciation had accrued but for which he had received no allowance, and partly because, with falling motor prices, the renewal cost becomes less than the original outlay, and some inspectors of taxes were apparently taking the strict technical view that in such circumstances the allowance must be based on the smaller value.

It may be convenient before leaving this question to refer to one or two practical considerations. It is clearly a matter of some difficulty to estimate with approximate accuracy the probable life of a motor car, and therefrom to deduce the appropriate annual deduction to be made. The difficulty is, we understand, met as a rule by taking an estimated rate (which is frequently 15 per cent. on the value as written down year by year), and when the car is eventually replaced giving, in addition to the previous deductions for obsolescence, a further allowance in the form of a professional expense equal to the excess of the total net actual cost of replacement over the depreciation deductions. Depreciation allowances are not regarded as expenses—that is, they are not deducted in calculating the profits of the separate years falling into the average period taken for the purpose of the assessment; those profits are calculated apart from any question of depreciation and the amounts of the allowance deducted from the average profits so calculated.

It would be premature at this stage to pursue this subject in greater detail; sufficient may have been said to show that the thanks of the profession are due to Dr. Fremantle for his assistance in securing an amendment of the income tax law which was certainly due in equity, and which should prove of real value to a class of taxpayers who deserve every consideration at the hands of the Exchequer.

## PROPOSED MEDICO-LEGAL INSTITUTE.

THE Medico-Legal Society (as mentioned in our issue of June 6th, p. 1039) proposes to establish a medico-legal institute, but, fully recognizing the many difficulties—financial, statutory, and otherwise—which stand in the way, the meeting which discussed the project at the Royal Society of Medicine on Tuesday, June 23rd, merely expressed a general approval of the idea and requested the committee which has the matter in hand to develop the proposal in co-operation with all interested parties. The objects of the proposed medico-legal institute were fully set forth by the president of the society (Lord Justice Atkin) and by Sir Bernard Spilsbury, the joint secretary. It is proposed that the new institute shall control the teaching and training of post-graduates, and so raise a body of specialists who will be available for posts such as those of coroners and police surgeons, and to effect this purpose the co-operation of the Board of Education, the University of London, and the Royal Colleges of Physicians and Surgeons is sought. A medico-legal museum is to be formed wherein will be housed pathological specimens which will afford special facilities for research. As Mr. Ingleby Oddie, the Westminster coroner, said, there is at the present time an enormous waste of pathological material in London alone. London, although the largest city in the world, will not be the first great metropolis to have established a medico-legal institute if the scheme succeeds. Paris has had such an institution these many years, whilst Vienna, Berlin, and Chicago are similarly fortunate. It is proposed to have a staff of medico-legal experts: a director of investigations, the holder of a chair of medical jurisprudence, a toxicologist, and a bacteriologist. Obviously, as Mr. L. W. J. Costello pointed out, the question resolves itself into one of finance. Sir Bernard Spilsbury said that

if such an institute came into existence the Government and such departments as the Home Office and the Ministry of Health would be closely concerned in seeing that it was satisfactorily developed. Also, assistance is hoped for from the public municipal bodies such as the London County Council, with its interests in the coronerships, and from the great examining and teaching bodies such as the University of London and the medical schools of the hospitals. Sir William Willcox, Sir William Collins, and Sir Walter Fletcher all spoke in terms of approval of the scheme, and the president urged that while to get it into proper working order would need considerable financial assistance, yet to begin in a small way was quite within the realm of present possibilities. If they had a great teacher, he said, even though he had only a shed to lecture in, they were bound to have a successful school: they must make a start. It is clear that if the Medico-Legal Society is willing to start a medico-legal institute in this way, so creating the need for housing lecturers and students and specimens before running into expenditure on building and charges of upkeep, the project may confidently be expected to succeed. Under the aegis of a president who is also the chairman of the Council for Legal Education, and a joint secretary who is eminent as the Home Office honorary pathologist, it is obvious that teachers of the highest standing will be available. All the other problems, financial and constitutional, will, we feel sure, under such favourable auspices resolve themselves as they arise.

#### TREATMENT OF ELECTRICAL ACCIDENTS.

CONSIDERING the extensive use of electricity and the serious nature of the accidents to which it may give rise, it seems desirable that both the laity and the medical profession should have a better knowledge of the subject; at present it appears to be lamentably defective. To remedy this Professor Jellinek has written a small book on electrical accidents.<sup>1</sup> As an indication of the seriousness of the situation he mentions that within the first nine months of 1924 nine fatal accidents occurred in Vienna alone. These were all low-tension accidents—seven of them due to defective lamps, two to faulty installation. All could have been prevented, given a little understanding of the problems involved; all the injured could have been saved if proper medical treatment had been instantly applied. Of the four modes of death from electrical shock described by the author, the commonest are sudden death and delayed death; in the latter the collapse and loss of consciousness are delayed for a few seconds or minutes, during which the patient attempts to extricate himself and calls for help. In both cases, however, it seems that death is for a time merely "apparent," and it is important for every medical man to realize that the so-called primary signs of death (absence of consciousness, pulse, and respiration) are in themselves insufficient, and that it should not be concluded from them alone that a man is dead; the doctor should not rest satisfied that death has occurred until there is hypostatic discoloration of the body. This may not appear for one, two, or more hours, and artificial respiration should be continued up to that time. Another point of importance is that the artificial respiration should be applied instantly and should be continuous; a few minutes, even seconds, may make all the difference in the result, and if artificial respiration is being employed on the arrival of the medical man he should not interrupt it to make inquiries as to the nature of the case. A third point is that the method should be applied *secundum artem*; both the laity and the profession are, according to the author, defective in this matter owing to lack of proper instruction. It may be observed that

artificial respiration is not mentioned in the textbooks among the causes of multiple fracture of the ribs, but many pathologists, from their *post-mortem* experience, would be inclined to include it in the etiology. In any case the author is right in suggesting that intelligent efficiency rather than force should be the guiding principle. In discussing the arrangements made in factories and other institutions for dealing with electrical accidents, Jellinek dwells on the futility of hanging on the walls of the building plentiful directions as to how workmen should act in cases of emergency. He gives examples of the mental vacuity usually displayed under this system. In one instance a man accidentally received an interrupted current of 220 volts, and shouted for help; all the other persons present hurried from the room. Several other similar cases are mentioned. Again, an electrician was inserting an arc lamp on a bridge when he became electrified with a current of 220 volts and was unable to free himself. The man detailed to look after the electrician's safety, instead of endeavouring to release him, ran to the nearest telephone, according to "instructions," in order to inform the Life-saving Society of the occurrence; meanwhile the electrician died. The author points out that nothing is of any use short of actual practice in the measures to be adopted in cases of emergency, as is now generally done in case of fire. The essentials are, in the first place, to extricate the man from the current, and secondly, to treat the apparent death instantly and continuously with artificial respiration. To do these things promptly and efficiently requires previous actual practice. Other practical matters are dealt with in this good and useful essay, including the danger points in electrical installations, the action of electricity on the organism, the interesting problem of the influence of personality as a defence against the action of the electric current, and the pathology of the subject.

#### TRANSMISSION OF DENGUE.

SINCE the original work of Graham in 1903, of Bancroft in 1905, and of Ashburn and Craig in 1907, there has been some doubt as to the part played in the transmission of dengue by the mosquitos *Culex fatigans* and *Stegomyia fasciata* respectively. We pointed out on March 10th, 1917 (p. 339), when referring to the investigations of Cleland, Bradley, and McDonald in Queensland and New South Wales during 1916, that further experiments were necessary to prove whether *Culex fatigans* could propagate dengue. We added that the mosquitos should be bred from larvae and allowed to bite persons under control conditions. Experiments on these lines have now been organized by the Medical Department Research Board of the United States Army and other closely associated workers, and Lieut.-Colonel J. F. Siler, Major M. W. Hall, and Major A. P. Hitchens have published a summary<sup>1</sup> of experimental work at Manila conducted with a view to confirming or disproving the transmission of dengue by the two mosquitos mentioned; the time after the appearance of the initial symptoms during which the dengue patient continues to be infective to mosquitos; the length of time infected mosquitos are capable of transmitting dengue; and the incubation period of dengue in the human subject. All mosquitos used in the experimental work were bred from eggs, and every precaution was taken to prevent the infection from extraneous sources of the forty-two men who volunteered for the experiment. The hospital ward was carefully screened so that no mosquitos could enter. Of the forty-two volunteers subjected to biting experiments dengue was produced in twenty-five instances (60 per cent.), and the positive results obtained by Cleland, Bradley, and McDonald with regard to the transmission by *Stegomyia fasciata* were

<sup>1</sup> Der Elektrische Unfall. Von Prof. Dr. med. Stefan Jellinek. Leipzig and Vienna: F. Deuticke, 1925. (64 x 9 1/2 pp. iv + 142; 25 figures. G.M. 4.80.)

<sup>1</sup> Journal of the American Medical Association, April 18th, 1925 (p. 1163). A full report will be issued in the Philippine Journal of Science.

fully confirmed. The experimental evidence pointed to the conclusion that a patient with dengue fever was capable of infecting these mosquitos during, at any rate, the first three days of the disease. It appeared that the virus causing dengue fever must remain in the mosquitos for a period of approximately eleven days before the insect became capable of transmitting the disease to non-immune human beings. These mosquitos continued to be infective for a very long period, probably through the remainder of their lives. Five volunteers were submitted to the bites of *Culex fatigans* in which the dengue virus had been allowed to remain for a sufficient length of time to produce infection, but the results were entirely negative; these five volunteers were infected at once when *Stegomyia fasciata* was used. Attempts were made to reinfect twelve patients who had recovered from an attack of dengue which had begun between forty-one and one hundred and twenty-one days previously, by the injection into them of blood from patients in the early stages of the disease. It was found that 58 per cent. of these were immune, and those who did develop the typical attack of the disease were ill for an average of 2.8 days, as compared with the 4.8 days of the primary attack. These results appear to indicate that dengue is followed by a definite degree of immunity, but the refractory state does not compare with that of scarlet fever. The authors point out that the striking similarity between the mechanism by which both dengue and yellow fever are transmitted gives ground for the suggestion that the organisms causing the two diseases may fall into the same group. It is possible to find some clinical resemblances between mild attacks of yellow fever and typical attacks of dengue. The authors conclude that both diseases are caused by filterable viruses present in the peripheral blood of the patient, and that both may be produced by the injection into a susceptible individual of blood from an infected person or of a filtrate of it. Both are transmitted by the bites of the *Stegomyia fasciata* mosquito only, and the mechanism of transmission is practically identical in the two. The patient becomes infective to the mosquito during the first three days of the disease; the mosquito becomes infective about eleven days after the virus has been introduced into it, and (as has been said above) continues infective probably for the remainder of its life. The hope is expressed that further research in dengue may suggest other methods of approach to the unsolved problems relating to the epidemiology and control of yellow fever.

#### RADIUM TREATMENT OF MENORRHAGIA.

DR. R. T. LEWIS, in his annual report for 1924 on radium treatment at University College Hospital, gives it as his opinion that the results as gauged during three and a half years' experience in cancer of the cervix are "somewhat gloomy"; though great amelioration of distressing symptoms undoubtedly follows radiation, the progressive course of the cancer cannot be arrested. Similarly, in cancer of the body of the uterus and the vagina and vulva, radium has brought little prospect of cure. On the other hand, in conditions of menorrhagia the sphere of usefulness of radium therapy appears to be continually enlarging and its value more firmly established. Thus, of 32 cases of haemorrhage at the menopause whose early history was given in last year's report, Dr. Lewis finds 27 to be in good health without any recurrence of bleeding. In the menorrhagia of young women who present no sign of pelvic disease—the so-called essential menorrhagia—the records of the three and a half years amply demonstrate that radium is "of incalculable value in the treatment of intractable haemorrhage," and Dr. Lewis announces that this method of treatment is now employed as a routine procedure at University College Hospital. In menorrhagia due to

fibroids radium therapy is, in suitable cases, attended with good results. In general it may be said that fibroid tumours of a size greater than that of the pregnant uterus at five and a half months call for surgical treatment; radium therapy is most trustworthy when dealing with the smaller tumours. Thirteen cases of fibroids were treated by radiation during the year, and in eight of these amenorrhoea followed. Only two cases required a second treatment. Altogether in the last three years 36 cases of fibroids have been treated by radiation, and in 22 of these the menorrhagia has been completely cured. In 9 cases a second treatment has been given, and 3 more will probably require it. In 2 cases it was considered advisable to remove the uterus, though further radiation treatment might have been successful. The report gives a detailed history of all cases treated with radium in the twelve months ending October 31st, 1924.

#### THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE eighty-fourth annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at the University Buildings, Edmund Street, Birmingham, from July 6th to 10th. The newly elected president, Sir Frederick W. Mott, F.R.S., will be in the chair. Reports will be received from various committees, and it will be proposed that Sir John McPherson, C.B., M.D., Professor of Psychiatry in the University of Sydney, shall be invited to deliver the Mandley Lecture for 1926. On the afternoon of Tuesday, July 7th, Sir Frederick Mott will deliver his presidential address, and in the evening the Council and Senate of the University will hold a reception. The annual dinner of the association will be held on Wednesday evening. On Tuesday morning Dr. David Orr will give a lantern demonstration on the sympathetic endocrine system. On the morning of Wednesday, July 8th, Dr. G. A. Auden of Birmingham will read a paper on encephalitis lethargica and its psychological implications, and Sir Frederick Mott will give a lantern demonstration of the lesions of the disease. On Thursday morning papers will be read by Dr. Graves on the incidence of chronic sepsis in mental disease, and by Dr. Pickworth on the iodine content of thyroid glands. In the afternoon a visit will be paid to Hollymoor and Rubery Hill. On Friday a paper on the institutional treatment of mental deficiency, with special reference to occupational training, will be read by Dr. A. M. McCutcheon; this will be followed by a paper on delinquency by Dr. W. A. Potts, and by another on the psychopathic personality by Dr. Hamblin Smith. In the afternoon visits will be paid to Worcester, Warwick, and Stratford-on-Avon.

DR. EDWARD HINDLE, Milner Research Fellow of the London School of Tropical Medicine and Hygiene, has been granted leave of absence for two years to undertake, in conjunction with Major W. S. Patton, an investigation on the transmission of kala-azar in North China, on behalf of the Royal Society. During the past six months Dr. Hindle has been working on the biology and life-history of spirochaetes, and has also devoted attention to the prevalence of leptospira in the neighbourhood of London. He has been successful in finding these organisms, not only in Thames water, but in tap water and many other sources. He sailed for China on June 22nd, and on his way east will call at Calcutta to see the work of the Indian Kala-azar Commission. While in China the Kala-azar Commission of the Royal Society will have a central laboratory at the Shantung Christian University, Tsinau, where Dr. Hindle expects to arrive about the end of August.

## LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

It will be remembered that at the end of February, 1922, the Rockefeller Foundation offered to provide a sum of two million dollars towards the cost of building and equipping a School of Hygiene in London, subject to the condition that the British Government would make itself responsible for the staffing and maintenance of the school when established. The gift and its terms were gratefully accepted, and the Government, through the Minister of Health, undertook to provide funds adequate for the proper maintenance of the school. A small committee was set up to advise the Minister on the preliminary steps to be taken, and on its advice a site was procured in Gower Street, Bloomsbury, sketch plans were prepared, and provisional plans and courses of study drawn up. In May, 1923, the Minister of Health, with the concurrence of the Rockefeller Foundation, appointed a transitional executive committee, whose duties were to appoint a director, to arrange for amalgamation or co-ordination between the school and other institutions, and to prepare plans for the new school. This committee arranged that the existing London School of Tropical Medicine should become an integral part of the School of Hygiene, and provision was made for this in the school's new charter. In November, 1923, Dr. Andrew Balfour was appointed as the first head of the new institution, with the title of Director of the London School of Hygiene and Tropical Medicine. Until the school is completed the Rockefeller Trustees promised to make an annual grant of £4,000 towards salaries and other administrative expenses. Further than this, they have recently generously undertaken that the capital sum to be provided for building and equipment should be the value in sterling at February, 1922, of two million dollars—a sum of about £460,000—instead of the diminished amount which would be payable at the rate of exchange now obtaining.

### *The Tropical Division.*

Under the terms of amalgamation the old London School of Tropical Medicine has become the Tropical Division of the London School of Hygiene and Tropical Medicine. It retains its status as a school of the University of London, and gives instruction in all branches of tropical medicine and hygiene, and in parasitology as applicable to public health work in this country. For the present it continues to occupy the premises in Endsleigh Gardens, where the work has been carried on for several years past. Previously the school was situated at the Albert Docks, where, under the guidance of Sir Patrick Manson, it rapidly developed. Altogether no fewer than 3,000 students have attended its courses of study.

In due course the transitional executive committee relinquished its duties to a board of management, some members of which were appointed direct by the Minister of Health, while some were representative of a large court of governors which has been established, and to which the board will report annually on the work and progress of the institution.

### *Provisional Scheme of Work.*

As explained by Dr. Balfour in an article contributed to the Educational Number of the *BRITISH MEDICAL JOURNAL* last year,<sup>1</sup> the provisional scheme of lectures and practical work has been framed on broad lines and with due regard to the new regulations for the D.P.H. laid down by the General Medical Council in 1922. The scheme divides the work into six main departments as follows: (1) Applied physics, physiology, and principles of hygiene; (2) chemistry and biochemistry; (3) immunology and bacteriology; (4) medical zoology, parasitology, and comparative pathology; (5) epidemiology and statistics; (6) the principles and practice of preventive medicine, general sanitation, and administration. In each of these divisions instruction will be given at the school, with museum demonstrations and practical laboratory work, together with lectures and

demonstrations at associated institutions. In addition the teaching of tropical medicine will be continued and developed.

As regards the building of the new school on the Gower Street site, five selected architects have submitted plans, according to the specification provided, and from these the choice of a design is now being made.

### *Revised Curriculum of the Tropical Division.*

In the meanwhile the work of the Tropical Division of the School has continued in the existing house in Endsleigh Gardens, and developments are in progress along various lines. The curriculum has been extended; for the old twelve weeks' course one of twenty weeks is now substituted. In recasting the plan of study tropical hygiene has received particular attention; 3½ hours, as compared with 8, will henceforward be devoted to this subject. A short series of lectures on biochemistry, in its relation to diseases and hygiene of the tropics, has been included, and opportunities for clinical study will be increased. The revised schedule provides also for the institution of tutorial or seminar weeks, in which no systematic teaching is given, but instead there will be conferences between teachers and students, with museum demonstrations and clinical work. A powerful stimulus has been given to research by the establishment of a field station in Southern Rhodesia, the appointment of Dr. H. H. Scott as comparative pathologist to the Zoological Society, and the acquisition of a field station near St. Albans, financed by the Ministry of Agriculture, under the immediate direction of Professor Leiper. Further steps are being taken to give opportunities for research work by the creation of four new research studentships at the school, each of the annual value of £250; since there is now a large demand for tropical zoologists and entomologists, this may help to provide the right type of man for such posts. Plans for the future include the building up of a graphic museum of hygiene. The existing museum of tropical medicine will also be expanded on graphic lines, and with these ends in view it is intended to collect material in advance.

Further details are to be found in the prospectus and calendar of the Tropical Division, copies of which can be had on application to the secretary of the school, Mr. R. W. Harris, 23, Endsleigh Gardens, Euston Road, N.W.1. The winter term will begin on October 5th next, and the spring term on March 15th, 1926.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

A SITTING of the Commission took place on June 19th, Mr. H. P. MACMILLAN, K.C., presiding.

### *Visitations by Guardians.*

Mr. GEORGE HILL and Mrs. GLANVILLE, two members of the Wandsworth Board of Guardians, gave evidence on the subject of visitation. They considered that for visitation to be of any real value it should be informal and unnotified. The method of visitation carried out until a year or two ago, when the patients on visiting days were brought up and passed before the visiting guardians, was quite useless. Mr. Hill thought that the present system of visitation, without prior notification, was an efficient safeguard against ill treatment or other irregularity. He complained of the lack of classification according to mental condition of the patients which he found in the institutions he visited, in particular of puerperal patients being placed in insane wards. Mrs. Glanville said that within a three-mile radius of Epsom there were four large mental hospitals, and she thought that the very acute cases might all be in one building, while the other three buildings could be set apart for cases in various stages of recovery, the last of the three being the institution from which they were discharged. This would mean economy in working.

On the question of punishment, Mr. Hill said that he was satisfied that punishment went on in these institutions. He referred to one or two specific cases of ill treatment by attendants. He had known a man to be put into the acute ward by way of punishment; it was well known that there the other patients, who fought amongst themselves, would inflict punishment upon him. At the time when he came in touch with this case the man had been in the acute ward for three

<sup>1</sup> New Conceptions in the Teaching of Public Health, by Andrew Balfour, C.B., C.M.G., M.D., *BRITISH MEDICAL JOURNAL*, September 6th, 1924, p. 353.

or four days, and the reason given for putting him there was that he had tried to escape. He also complained of the padded room at Cane Hill Mental Hospital; it was dark and ill ventilated, but he admitted that his visit was paid rather late on a winter afternoon, also that it was necessary in such a room to have windows out of the patients' reach. At Hanwell the clothing of the male patients was not adequate in winter. Mrs. Glanville said that the clothing at other mental institutions was better than at Hanwell, but she did not know the reason for the difference. It was much to be preferred that patients should be allowed to wear their own clothing if suitable; any approach to a uniform was felt by sensitive patients.

#### *St. Luke's Mental Clinic.*

Dr. R. W. GILMOUR gave evidence with regard to the working of the St. Luke's Mental Clinic attached to Middlesex Hospital. St. Luke's was one of the oldest of the registered hospitals. For many years it received only certified cases of insanity. In 1923 a clinic was established at Middlesex, with six beds, the nursing staff being supplied by St. Luke's. One of the reasons for founding the clinic in association with a general hospital was that people would be more likely to attend, whereas the name of a mental hospital might deter them. Further, the fact that it was a general hospital to which they went helped them to realize that they were ill, and thus to some extent assisted treatment. In most illnesses expert examinations were necessary, and this was also the case at the clinic. The hospital neurologist and the witness saw the cases in the same room, and there was close association between the ward for mental cases and the other wards of the hospital. By such treatment many cases were prevented from reaching the stage of certification. Patients came of their own desire, they were told that they must obey the hospital rules, and if they seemed likely to give trouble he told them that he was taking their word, which was mostly effectual. Noisy patients likely to disturb others were not retained.

In reply to Sir David Drummond, the witness said that he thought a more general extension of this system would be a very good thing. A clinic purely for out-patients would be beneficial also. The cases he received were chiefly those of neuroses and psychoneuroses, but, contrary to the opinions of some, he was convinced that some of these cases passed into genuine psychoses. Several cases, though not certifiable when they came in, became so later. Certified patients were not received in the ward; that was essential to the character of the ward, for the patients were told that so long as they remained there they would not be certified, nor would they be associated with certified patients. The in-patients last year numbered 5 men and 20 women; 4 of the men and 14 of the women recovered. Of the remainder, 3 were removed by friends at the witness's request, and the others were discharged either relieved or not improved. There was no system of letting out on trial, as in mental hospitals, so that he had no knowledge as to how the patients got on afterwards. Not one of these patients passed from him straight to a mental hospital. Occasionally cases which had developed mental trouble in the general wards of the hospital were received into this ward. The nursing staff consisted of five female nurses, all with mental nursing qualification, and one or two with general hospital experience also.

#### *The Voluntary Clinic.*

At a further sitting of the Royal Commission on June 22nd evidence was tendered by Lady CHICHESTER, the president, and Dr. HELEN BOYLE, senior physician, of Chichester House, Hove, Sussex.

Lady Chichester stated that this hospital was instituted in 1905 as a voluntary hospital for dealing with early nervous and border-line cases in women and children. It had 23 beds and an out-patient department. The average period of residence of an in-patient was three months, and the average cost of an in-patient per week was £1 19s. 7d. The moderateness of this amount was due to the fact that only a small staff was employed, the patients being able to co-operate in the working of the hospital to a considerable extent. No cases at all were taken on discharge from a mental hospital; such cases were left to the After-care Association, but after-care principles were followed to this extent that a person who had been a resident at Chichester House was encouraged at any time to come back to the out-patient department for further advice.

Dr. Boyle said that it was extremely desirable that such a clinic should be in association with a general hospital, and when Chichester House was started it offered itself to the Royal Sussex County Hospital, but the idea at that time was not entertained. It was equally important that such a clinic should have no association with a mental hospital. She spoke from a considerable experience of American and European clinics. The drawback of many of the clinics she had seen abroad was that

they took cases which were too bad for a clinic to take. Professor Winkler's famous clinic at Utrecht was really a great clearing house. That and other clinics of the kind had locked doors, which neutralized the chief advantage of early treatment. Asked which country dealt best with this problem, she said that no country had a monopoly, but the boarding-out system was best in Belgium.

Sir David Drummond remarked that most hospitals in this country admitted the kind of cases treated at Chichester House. Dr. Boyle, however, did not think that general hospital treatment was altogether satisfactory, and this seemed to be proved by the fact that the staffs of general hospitals sent cases to her own institution. Asked what was done when in her clinic a case suddenly developed acute mental symptoms, she said that the relatives were immediately communicated with, and the patient was sent home, if necessary in the company of two nurses. Acute mental cases should not go to such clinics at all; they should go to the mental hospital. She did not want acute recoverable cases to be removed from the domain of mental hospitals, otherwise those institutions would become homes of despair. On the other hand, the clinics, if they did not receive acute cases, would commend themselves better to the general hospitals with which it was very desirable that they should be associated.

Sir Humphry Rolleston noted that a certain number of early cases of disseminated sclerosis were admitted to Chichester House; did not that institution have its hands full with the psychoneuroses? Dr. Boyle defended the right to admit into such an institution all nerve cases, even if there were no signs of functional disturbance. She wanted to maintain the conception that the nervous system should be treated as a whole. Her institution had access to the laboratory of the Sussex County Hospital, so that pathological detail could be investigated there as well as anywhere else.

#### *Nursing Homes.*

Dr. Boyle went on to give, at the request of the Commission, certain opinions of her own with regard to certification and cognate matters. She thought that a doctor should be free to treat a willing patient whenever he thought it desirable or possible, and that the patient should be free to go where he wished to be treated or where the doctor wished to send him—in other words, she would allow an unlimited number of licensed or private houses. Instead of the present monopoly in private houses, she would have free competition. With free competition it was very unlikely that there would be serious abuse. The good houses would survive and the bad houses disappear. Public opinion, the friends of the patient, the nurses and servants employed in the institution, all combined to form a better safeguard against abuses than any system of legal supervision could possibly do. The only bad nursing home she had ever known was one which was under supervision, and the fact of supervision lulled the public into a false sense of security with regard to its management.

Dr. Boyle also expressed the view that from time to time certified patients in asylums should be changed from one institution to another. This would cause many chronic patients to give less trouble; the prejudices which they might feel against particular attendants would no longer operate. Indeed, to stay too long at one place encouraged the chronic condition.

#### *Maudsley Hospital.*

Dr. EDWARD MAPOTHER, Medical Superintendent of Maudsley, also gave evidence. The Chairman of the Commission (Mr. H. P. Maemillan, K.C.) mentioned that, a few days previously, the members of the Commission had had the advantage of paying a visit to Maudsley, and of inspecting the different departments employed in discharging the three functions of the hospital—research, teaching, and voluntary treatment.

Dr. Mapother said that he desired to give evidence, not as an officer of the London County Council, but as an individual with a good deal of experience of asylum administration, and to urge certain general lines of reform of the existing system. In the first place, he held that there should be more adaptation of the legal formalities to the patient's attitude towards treatment. At present, for the poor, certification was almost everywhere an absolute preface to treatment, whereas his ambition would be to make treatment a means of avoiding certification. In the second place—a thing upon which he laid the chief stress—he wanted to see the provision or approval of specialized types of institution which would deal separately with recoverable and with chronic cases, and separately also, in each of these classes, with patients, on the one hand, who were objecting or objectionable, and, on the other, with patients who were, in the widest meaning of the word, quiet. His third principal point was to urge the extension of the present provision for teaching and research.

The classification of patients in respect to the degree of volition which they possessed was very important. Among certifiable patients there were, first of all, those who were able to co-operate in their own treatment; secondly, those who were negative (that is, neither co-operating nor resisting); and, thirdly, those who actively resisted. He thought that at present in asylum administration there was an excessive tendency to consider that certifiable patients were to be regarded as unwilling unless there was definite evidence to the contrary; whereas in his view they should be regarded as willing unless the contrary was clearly shown.

Clinics, of course, were of the very greatest use, but there was a definite limit to their usefulness. In some cases they were certainly not a substitute for mental hospitals. In Maudsley there were no certifiable patients. All the patients were entitled to discharge on giving twenty-four hours' notice. Three-fourths of the Maudsley patients came through the out-patient department in the first instance, having in very many cases been sent to the out-patient department by their own doctors; those who did not come by way of the out-patient department came usually on the recommendation of a mental specialist. He attached much importance to having no certifications carried out at Maudsley. The willingness of the people to approach the institution voluntarily depended upon the knowledge that they would not be certified, or, in other words, that they could leave when they liked. He thought that all of them appreciated the voluntary nature of the institution, save perhaps a few whose intellects had been clouded since admission. More severe cases—though still willing and recoverable—were taken at Maudsley than at Chichester House.

In answer to the Chairman, Dr. Mapother said that the voluntary submission on the part of a patient for a definite period of residence in an institution would be a very useful thing in certain cases, such as drink and drug cases; there were also a number of patients who from day to day could hardly make up their minds whether they wanted to go or stay, and if the problem were solved for them they would be easier in their minds. He thought that the non-volitional patient should be dealt with in the clinics, provided such a patient was not objectionable to others. These non-volitional patients included many recoverable cases. Such cases were not taken at Maudsley Hospital at present, but in the clinic of the future they should be admissible.

#### Observation Hospitals.

Dr. Mapother went on to urge that fresh cases which were recoverable, but were unsuitable for treatment at clinics, should be first treated at observation hospitals, which would take the place of the present observation wards in workhouses. First of all there would be the voluntary clinic for out- and in-patients; then the observation home, to which patients who had ceased to be voluntary or were incapable of being managed in a voluntary clinic could be sent for observation and treatment, and as the last resort there would be the asylum. Some cases would go first to the observation home, without passing through the clinic, but he thought that before any case went to the asylum it should pass through the observation home.

Another reform which he would like to see brought about was for patients who came short of certification to be permitted to become voluntary boarders in private care; at present such patients could not be in private care unless they were certified. The private care of these voluntary patients should be subject to supervision and visitation in the same way as certified cases.

He deprecated in the present asylum administration the mixing up in one institution of different types of cases. If each institution had its own type of case contentment would be promoted, and the advantage of such a classification if voluntary patients were admitted to mental hospitals were obvious. Resistant patients might be confined to one or two institutions. At present, however, the wards were classified, both refractory and quiet patients came into association in the gardens. The isolation of the chronic refractory patient in one institution was the only remedy. Patients whose violence lasted only a short time should be treated in one of the institutions for quiet patients, but a separate ward should be provided.

He mentioned that he had known a number of nurses—male and female—who had extraordinary skill in dealing with refractory patients, and some of them were so much engrossed in this work, which they regarded as a vocation, that they would threaten to resign if they were moved into a "quiet" ward. He was in favour of female nurses in male wards. At Maudsley this employment of female nurses had led to a very slight restriction in the class of patients taken—very much slighter than might be imagined, because some of the most difficult patients were more manageable by women than by men.

He wished to see other Maudsleys serving different centres of population, and he expressed the view that it would be an advantage economically and no disadvantage in other respects if the accommodation of Maudsley were doubled.

## Nova et Vetera.

### MEDICAL MEN MENTIONED ON THE PIPE ROLLS (1156/57—1186/87).

NEXT after Domesday Book, the Pipe Rolls are the most important of the public records of the kingdom. They are the accounts of the sheriffs of the counties of that revenue for which each was responsible annually at the Royal Exchequer. They also include statements of the expenses of the sheriffs in the King's service. The earliest in date of these records is the roll for the thirty-first year of Henry I (1130). This was published in 1833. The next rolls to be published (1844) were those for the first, second, and third years of Henry II. From the first year of this Henry the series is almost complete to the nineteenth century. Among the early specimens issued by the Record Commission, besides the early Pipe Rolls for the last year of Henry I and the first three years of Henry II, was the roll for the first year of Rielard I and that for the third year of John. The Pipe Roll Society was founded in 1883 to complete the gaps between these early publications. The society issued its thirty-seventh volume in 1915, and then succumbed to the war; last year it was resuscitated, and it is hoped that the first volume of its new venture will shortly be in the hands of its members.

The volume containing the earliest roll is practically unobtainable at the present time; I have the second volume and a complete set of the *Transactions* of the society, with the exception of Vol. 24, which is unobtainable.

The first medical item on my list is as follows.

4 Henry II (1156/57).—"Et in Liberationes Constitutae Johanno Medico. xxxs. et vd."

"Liberationes Constitutae" were certain fixed payments charged on the King's lands. This occurs on the roll for Essex. In the same year under Northants:

"Et Radulfo Medico in terris datis xv libras numero. Et quietus est."

"Terrae datae" meant lands which the King had granted away from the *Corpus Comitatus*. The issue of the lands being no longer received by the sheriff, he had an allowance for them when rendering his account at the Exchequer. In the following year Dr. John's 30s. 5d. appears on the roll for Essex, but is not mentioned again in any subsequent year.

5 Henry II (1158/59): Essex.—"Et in perdonis per breve Regis. Et Radulfo Medico iii marcas. Et quietus est."

"Perdonae per breve Regis" were discharges of debts by writs or mandates of the King. The record expressly states that Radulfus was quit. In the same year under Northants:

"In terris datis. Radulfo Medico. xx libras. Et quietus est."

And under Hants:

"Et Girardo Medico Henrici filii Regis es."

The roll for the sixth year of Henry II does not appear to contain any medical entry.

7 Henry II (1160/61): Notts and Derby.—Under "Nova Placita et Novae Conventiones": "Et Radulfo Medico xxvss. et viiid."

And under Essex:

"Et in perdonis per breve Regis, Radulfo Medico iiiii libras."

8 Henry II (1161/62): Northants.—"Et Radulfo Medico vs. et quietus est. Et Radulfo Medico xiiiiis. et viiid."

This 14s. 3d. of Dr. Ralph's is mentioned again in the same year under the Bishop of London "in perdonis per breve Regis," and again in the following year under the same heading. The rolls for the next two years are free from medical entries.

12 Henry II (1165/66): Northumberland.—"Idem Vicecomes reddit Computum de ixs. et xd. de terra Geruasi Medici. In Thesaurio liberavit in II tallis. Et quietus est."

This entry is found in the roll for the next eight years and again in that for the year 1177/78. In the first entry only is the word "tally" found.

In the same year, under Notts and Derby, in the Honor

of William Peverill, under "Nova Placita et Novae Conventiones":

"Henrici Medici reddit Computum de xxvis. et viiid. per fugatorio. In Thesauro liberavit et quietus est."

This 26s. 8d. appears to have been due for the worth either of a fugitivo or more probably for the worth of the goods of the absconder. In any case, Dr. Henry had paid the sum and was quit.

13 Henry II (1166/67): *Northants.*—"Idem Vicecomes reddit Computum de xls. de Gaitintona, Radulfi Medici. In perdonis per breve Regis. Ipsi Radulfi xxxiiis. et iiiid. et debet dimidiam maream."

There was also a little matter of xxs. owing from the same Ralph from lands in Berton. This appears to have been paid, and in the following year he paid up his half-mark due from Gaitinton, but he was not yet out of trouble, for in 1168/69, on the plea of Alan de Nevill, "Gaitintona Radulfi Medici debet iii marcas pro iii fabricis factis in forestam," and the debt of 4 marks appears on the roll for the next year. It does not seem ever to have been paid.

17 Henry II (1170/71): *Notts and Derby.*—Henricus Medicus appears with others for a sum of money "in operatione" Nottingham Castle. This entry occurs in all succeeding rolls for my period. The Latin word *aula* is used in some of the later entries instead of *castellum*. I think that Henry must have been an important person to have had anything to do with Nottingham Castle, for in mediæval times this fortress was one of the most important strategic points in England.

18 Henry II (1171/72): *Hants.*—"Et in speciebus et electuaria per Josephi Medici x libras et viis."

21 Henry II (1174/75): *Lincs.*—"Robertus Medicus de Axford debet i maream."

This occurs under "Nova Placita et Novae Conventiones" of Ranulf de Glanvill and Hugh de Cressi. In the following year it is noted that he renders his account for "one mare," there is "in thesauro" half a mark, and he owes half a mark. In the next year he paid it and was quit.

23 Henry II (1176/77): *Cornwall.*—"Et Jordano Medico xs. in Carneto, per breve Regis de dimidio anno et amodo xxs. per annum."

This sum is entered against Dr. Jordan in all the succeeding rolls of my period.

26 Henry II (1179/80).—"Gilbertus Medicus reddit Computum de v marcas quia pugil suus quem plegiavit retraxit se de duello. In Thesauro 2½ marks et debet 2½."

In the same year: "et de lxs. de Wilclmo pugili Gilleberti Medici pro recreantia."

Under Wilts:

"Robertus Medicus et Osbertus filius Reginaldi et socii eorum reddunt Computum de i maream quia non habuerunt quos plegiaverunt. In corredio Regine liberavit per idem breve. Et quietus est."

In the next year Gilbert rendered his account of 2½ marks "quia pugil suus quem plegiavit retraxit se de duello."

"In Thesauro xviss. et viiid. et debet xviss. et viiid."

In the following year he paid his 16s. 8d. "de misericordia pro duello," as a fine for the duel,\* and was quit.

31 Henry II (1184/85).—"De oblati Curiae. London et Middlesex. Cecilia uxor Roberti Medici debet xxs. pro recto de ix marcas versus Ricardum Speciarum."

32 Henry II (1185/86).—"Et in procuracione Godmanni Servientis Regis et Medicorum ejus, et pro medicamentis et victualibus et pannis et aliis necessariis eorum dum idem Godmannus apud Londinensem infirmabitur £6 13s. 4d. per breve Regis."

33 Henry II (1186/87): *Warwickshire.*—"Lambertus Medicus debet e libras pro dissaisina injusta."

This was at the plea of Richard, archdeacon of the county, and his fellows.

This is my last entry. I regret to have to end this article with a note of what appears to have been a swindle by a dishonest rascal of a physician in these early times. One only hopes that he paid his 100 pounds at some later date.

R. R. JAMES.

\* Duellum=trial by battle.

## England and Wales.

### HOSPITAL ACCOMMODATION IN SOUTH WALES.

At a recent meeting of the Cardiff Medical Society Dr. Colston Williams, in opening a discussion on the provision of hospital accommodation, summarized the major defects revealed by the inquiry of the Voluntary Hospitals Subcommittee in South Wales. He doubted whether voluntary hospitals could adequately meet the needs of the future. In South Wales more beds for medical cases were required, particularly for women and children, and also better facilities for treating orthopaedic conditions and conditions of the eye, ear, nose, and throat. Dr. R. Picken said that the population of Cardiff and East Glamorgan, numbering approximately 800,000, had access to only about 850 beds, of which 460 were in Cardiff. There was a possibility of adding a further 400 beds. The waiting list at Cardiff Infirmary was over 1,800. On a conservative standard of 2 beds per 1,000 of population, 750 additional beds were needed for the area; if a higher standard of 3 per 1,000 was adopted the number of beds required would be 1,550. In the area there were about 1,100 beds in Poor Law institutions in the area, with the prospect of the addition of a further 650. More use might be made of the fever hospital accommodation for such diseases as pneumonia, and more beds were needed for tuberculous patients. Voluntary subscriptions were not likely to be forthcoming in sufficient amount, and voluntary hospitals were unwilling to accept State assistance. The Poor Law authorities might be encouraged to increase their accommodation with the assistance of Government subsidies and with co-ordination through the Ministry of Health. Health authorities might also be stimulated to provide hospital accommodation for preventive work, including ante-natal, maternity, and infant wards, with open-air residential schools. Dr. B. Llewelyn Williams pointed out the need of closer co-operation between the existing voluntary hospitals, which should deal with acute cases requiring specialized surgical or medical treatment, while the Poor Law hospitals should treat primarily those patients whose main need was skilled nursing. The voluntary and the Poor Law hospitals should work together to a greater extent in Cardiff than was at present the case. The large city hospitals should similarly co-operate with small local ones, and patients should not be removed from their own neighbourhoods unless the local hospital was unable to deal with the case. There was much to be said for admitting to the staffs of these local hospitals all doctors practising in their vicinity who could take their share of the hospital work, with the assistance of physicians and surgeons of consultant rank from the larger hospitals.

### HEAT IN THE TREATMENT OF DISEASE.

During the recent course in medical hydrology at London University, Dr. R. Fortescue Fox delivered a lecture on the use of heat in the treatment of disease, with special reference to rheumatic affections and catarrh. The report by the Ministry of Health on the prevalence of rheumatism in England has necessitated fuller consideration of the use of physical remedies in this disease, and the lecture embodied an account of the rationale of treatment by heat. Dr. Fox pointed out that physiologists had shown that normal animal metabolism rose to an optimum at a definite temperature, and that the close connexion between disease and body heat was indicated by the rise of temperature after microbial invasion, which appeared to be a necessary reaction in the process of recovery from acute illness. This connexion was also indicated by the depression of body temperature in chronic disease, a condition unfavourable to recovery because it signified impaired metabolism and a deficiency in the normal reaction to the disturbing causes. The lecturer added that the hottest baths were always associated with the coldest climates. Since the earliest times the northern peoples, including the North American Indians, Laplanders, Finns, Russians, and Chinese, had made habitual use of extremely hot vapour baths followed by exposure to cold, and a similar bath was used in ancient times in this country; in Greece and Rome more moderate

temperatures were employed. The heat bath, about 104° F., increased the temperature of the skin and body, the peripheral circulation, the volume of the circulating blood, and metabolism, whilst it lowered blood pressure. The cold bath, about 60° F., produced at first the opposite results, but later a nervous reaction occurred with stimulation of the nervous centres, and indirectly of the heart and respiration, thus increasing the activity of the circulation, the metabolism, and the body heat. The medical use of cold bathing appeared to be quite modern, and became extreme in the nineteenth century. Cold baths were dangerous for delicate people, invalids, and the aged, because in them the normal power of reaction to cold was defective or in abeyance; such people were "susceptible" to chill. This chilling, or actual lowering of the temperature of the body, signified the uncompensated removal of heat; the demands on heat production could not be met. While a few invalids always felt warm, the majority felt the cold; these conditions were probably associated with the basal metabolism and heat production in connexion with endocrine activity. Such chronic chilliness, generally associated with catarrh or metabolic disorders, might lead to serious illness, such as pneumonia, inflammation of the stomach, liver, and kidneys, or rheumatism. In many of these people illness might be prevented by the periodical systematic use of heat, followed by cold, the defective reaction to cold being thus repaired. Climates might be divided into (1) the hot and moist, prevalent in some parts of England, and beneficial in chronic catarrhal conditions and fatigue; (2) the hot and dry, or desert climates; (3) the cold and moist, with which British medical practitioners were mostly concerned, which were responsible largely for catarrh and for rheumatism; and (4) the cold and dry, exemplified by the winter climate of Canada and of high mountains, and in a milder but most valuable form by the east coast of Great Britain. The following indications for the use of heat were noted. In the prevention and treatment of catarrhal conditions the systematic use of contrast vapour baths was likely to be very beneficial. Dry, cool inhalation of finely divided particles from chloride springs had proved very valuable in respiratory catarrhs, especially in the case of children with enlarged glands and tuberculous bones and joints. Brief (60 to 80 seconds) hyperthermal baths (108° to 120° F.) were efficacious in the defective circulation associated with gastro-intestinal catarrh and Raynaud's phenomena. The painful exudations and deposits in the neighbourhood of joints and other fibrous tissues should be treated systematically by heat, the dosage being most important, and reaction being the chief guide. A series of very small and almost imperceptible reactions were the ideal, since these favoured recovery. The treatment of rheumatism at health resorts and physical clinics should extend over several weeks, the patient being warmly housed, as there was considerable danger of chill after the baths. At the close of the course the patient should be gradually hardened by exposure to cold. In all forms of traumatism the use of heat was indicated at one stage or another to relieve pain and tension and to promote absorption. In many cases, whether rheumatic, traumatic, or paralytic, the heat applied, as in the whirlpool bath, was a good preliminary to the manipulation and movement of injured parts of the body.

#### ALTON CRIPPLES' HOSPITAL.

Founder's day at the Lord Mayor Treloar Cripples' Hospital, Alton, was celebrated on June 20th, when a bust of Sir William Treloar, erected in the grounds of the hospital, was unveiled by the Lord Chancellor (Viscount Cave). The memorial is a gift of a circle of personal friends. The Lord Chancellor, in response to a vote of thanks, proposed by the Right Hon. T. P. O'Connor, M.P., said it was a great honour to be allowed to unveil such a striking likeness of his old friend, whom those present did not look upon as an administrator or magistrate, but as the children's alderman and the children's lord mayor. For thirty years Sir William Treloar had carried on the Crippled Children's Christmas Hamper Fund; had been the moving spirit in the children's feast at the Guildhall, and his acquaintance with the crippled

children of London had led him to organize the hospital at Alton and the home at Hayling Island, which were both doing such excellent work. At a meeting subsequently held in the college, the chairman, Lieut.-Colonel Lawson, emphasized the necessity of clearing off the debt incurred by building the isolation hospital, and the urgent need for extending the nurses' quarters. The institution required continuous and increasing support in order that it might do its work efficiently.

#### NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

The foundation stone of an extension of the out-patients' department of the National Hospital for Diseases of the Heart, in Westmoreland Street, Marylebone, was laid on June 13th by Colonel Walter Faber, Grand Master of the Order of Crusaders. The Crusaders, to the number of 250, all clad in mediæval habit and carrying insignia, walked in procession along the streets between the parish church, where a preliminary service was held, and the hospital. In reply to a welcome from the secretary of the hospital, Colonel Faber said that he rejoiced that the Order's first public act of service should be devoted to the help of such an institution. The stone having been duly laid, Mr. E. R. Morris, C.B.E., chairman of the hospital, delivered an address in which he recalled that this hospital was founded in a small house in the neighbouring Margaret Street sixty-eight years ago. It was the first hospital—and still remained the only hospital in the world—devoted entirely to the special study and treatment of heart conditions. Special heart departments had since been established in general hospitals, thus justifying those who in the middle of the last century decided that cardiac conditions were so very important as to deserve an institution for themselves alone. After various removals to larger premises the hospital found its present home, and now a site adjoining the building had been acquired for the badly needed extension of the out-patients' department. In that department some 35,000 attendances were made every year, and the number of in-patients treated was from 350 to 400, the average period of stay being seven weeks. The cost of the work was £10,000 a year, and to carry through the extensions now begun the sum of £7,000 was needed.

#### LONDON AMBULANCE SERVICE.

A report on the London ambulance service was presented to the London County Council on June 23rd. During the year ended March 31st, 1925, the total number of calls dealt with by the ambulances was 31,700; of these, 5,000 were dealt with between the hours of 11.30 p.m. and 7.30 a.m. The average time taken to reach a case was 7.4 minutes. During the busiest hours on week-days thirteen ambulances are in commission, but under present arrangements this number is reduced to eight on Sundays. The number of cases dealt with on Sundays, however, shows a continual increase. On the first three Sundays of last May the calls were respectively 57, 77, and 83. Calls on the ambulance service continue to increase year by year; the highest number in any one year since the inception of the service was made in the year ending March 31st, and the number for the first quarter of the present calendar year exceeds the number for the corresponding quarter of 1924 by 600. The highest number of calls ever recorded on a single day (161) was on a recent Saturday (May 16th). The statistics show that the calls are most frequent during July; in July, 1924, the number of calls dealt with was 3,002. It is proposed to place in continuous commission from July 1st next three ambulance stations (Battersea, Highbury, and Paddington) which have hitherto been subsidiary—that is, have been closed during certain hours of the night and on Sundays.

#### MILLER GENERAL HOSPITAL.

Active work upon the extension of the Miller General Hospital for South-East London has been started. The hospital at present contains one hundred beds; the new building will comprise a block with three wards, each containing twenty-four beds, and six single-bedded rooms. In the basement of this block there will be a dining-room and classroom for the nurses; adjoining the block a main kitchen is to be provided, with storage accommodation, and

dining and recreation rooms for the maids. The new nurses' home will contain seventy-three bedrooms, as well as sitting-rooms, and will be capable of enlargement at a later date. The cost of the present extension will probably approximate £100,000. King Edward's Hospital Fund has promised £16,000 towards the cost, and at the present time the sums promised or received amount to about £60,000. The annual report of the hospital for the year 1924 shows that the expenditure exceeded the income by £489; the work of the hospital and of its convalescent home at Bexhill costs annually nearly £23,000. During the year 1,555 patients were admitted to the wards, an increase of 70 over the previous year.

## Scotland.

### MILK AND DAIRIES ACT.

THE Milk and Dairies (Scotland) Act, 1914, comes into operation on September 1st; it imposes important duties on local authorities, and their attention has been drawn to its provisions in a circular issued by the Scottish Board of Health, dated June 16th. The local authority may appoint a committee or committees for the exercise of its powers under the Act. The Act authorizes any local authority to whose district milk is sent to complain to the local authority of the district from which the milk originates if the former local authority has reason to believe that the provisions of the dairy by-laws are not being carried out. Power is given for the appointment of a veterinary inspector or inspectors, who are to be whole-time officers. Neighbouring authorities may combine for the appointment of a veterinary inspector, which must be sanctioned by the Board of Health. Inspection of dairies is to be carried out at least once a year, either by the veterinary inspector, the sanitary inspector, or the medical officer of health of the district, and powers of inspection are also to be conferred on similar officers of other districts in regard to milk consigned out of their district. All dairies must be registered with the local authority, which has power to revoke a certificate if the dairyman is or becomes unsuitable for carrying on the trade or if the premises are or become unsuitable for the purpose of the trade. Further, where milk is sold from a cart, van, or other vehicle within a district, such vehicle must be registered as premises within any district in which milk is sold from it. Various special measures are indicated for the prevention of disease; thus it is provided that the milk from a cow suffering from certain specified diseases shall not be sold for human food. Further, that a dairyman must give written notice to the local authority of any cow which appears to be suffering from any sore on the teats accompanied by suppuration or bleeding and on becoming aware that any person resident at or employed in connexion with his dairy shows symptoms of any infectious disease. Further, persons suffering from diseases which are enumerated, or who have been in contact with such persons, are not to assist in dairy work except under specified conditions. Powers are given to the local authority to stop the supply of milk in its district from any given dairy, and to require from dairymen lists of customers when the medical officer of health certifies that an outbreak of infectious disease is in his opinion due to the milk supply. Powers are also given to the veterinary inspector to apply the tuberculin test to any cow with the consent of the owner, and to local authorities to establish depots for the sale of milk specially prepared for consumption by infants under 2 years of age.

### RESEARCH SCHOLARSHIP IN NEUROLOGY.

At a meeting of the University Court of the University of Edinburgh held last week, it was intimated that a legacy of £5,000 had been received from the estate of Miss Catherine S. Howden to found a scholarship for research work, preferably in the domain of nervous diseases. Intimation was received at the same meeting that a party of 175 Canadian undergraduates were to visit Edinburgh from July 6th to 10th, under the auspices of the Overseas Education League. It was decided to invite them to an afternoon reception in the McEwan Hall.

### ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

The annual meeting of contributors to the Royal Edinburgh Hospital for Sick Children was held on June 16th. Sir John R. Findlay, Bt., chairman of directors, who presided, in moving the adoption of the annual report, regretted that the number of Edinburgh contributors and the amounts contributed remained small, despite the fact that the work of the hospital was of great public importance. He referred to the retirement of Mr. Fraser, surgeon to the hospital, who had been appointed professor of clinical surgery in the University, and of the matron, Miss Burleigh. The report showed that 2,727 cases had been treated in the wards during the year, as compared with 2,657 in 1923; of these, 1,543 were medical and 1,154 surgical. The average daily number of patients in the hospital had been 114, and the average duration of residence sixteen days. There had been a large out-patient attendance, the new medical cases having numbered 3,038, with 6,004 re-attendances; the new surgical cases had numbered 3,305, and re-attendances of these 11,133. In the out-patient department, 2,054 minor surgical operations had been performed, and in the ear and throat department 615. The total number of patients to whom the hospital had given assistance during the year was 29,553, as compared with 31,166 in the previous year. Total ordinary income had been £11,134, and the ordinary expenditure £15,815, leaving a deficiency of £4,681. This had been met by using about half of the legacies received during the year, which would normally have gone to capital. The report drew attention to the continued increase in the number of in-patients; the directors consider it inevitable that before long additional accommodation will have to be provided. Attention is also drawn to a clinic for mentally defective children established by Dr. John Thomson; in the twenty years during which it had been carried on it had dealt with nearly nine hundred cases. Many of these cases had been treated and supervised for several years, and the clinic had been of great service both to the hospital staff and to the medical profession in Edinburgh and beyond it. Professor Gulland, President of the Royal College of Physicians, who seconded the approval of the report, said that in his student days there had been very little teaching in regard to children's diseases, while now every student had to go through the course. He believed that there was no part of the student's training which was so useful in general practice as the training he got in the wards of the Sick Children's Hospital, where excellent work was being done.

### CARE OF THE EDINBURGH BLIND.

At the annual meeting of the Royal Blind Asylum and School, Edinburgh, the Rev. Dr. Thomas Burns, chairman of directors, who presided, said that the outstanding feature of the year had been the admission of fifteen blind persons for technical training; in a year or two they would be able to take their place as efficient workers. The directors hoped that in course of time a generally higher standard of efficiency would be attained by all blind employees, and there was reason to expect that infantile blindness would be reduced more and more. He believed that local efforts had had the effect of stimulating interest in the welfare of the blind in other parts of the Empire. The subject had recently assumed such importance as to influence Parliament in passing measures to meet requirements, but further legislation was necessary. He considered that there was more and more evidence of a need for the provision of residential homes for elderly delicate blind persons whose relatives were not able to give them the care and attention they required. This applied particularly to women.

### MONTROSE ROYAL ASYLUM.

The report presented to the annual meeting of Montrose Royal Asylum held on June 10th showed that there were on May 14th last 754 patients in the institution; the certified cases numbered 131, or 26 less than in the previous year. The average age of admission had been 45.9 years; 2 patients were under 15 and 13 over 70 years of age. Out of the causes of mental breakdown some physical disease had been responsible in 35 cases, while a hereditary tendency to insanity could be traced in one-third of the cases admitted. Dr. C. J. Shaw, physician superintendent, points out that pauperization, certification, and the stigma which attaches

to asylum care are serious obstacles to the treatment of mental disease at an early stage, and he comments upon the difference that exists in the attitude of the public in attaching a stigma to treatment in an asylum while placing no stigma upon treatment in, for example, a hospital for infectious disease. He thinks, however, that the public are developing a different attitude towards mental hospitals, and that this is largely due to the introduction of female nurses into asylum wards. When it is realized that the primary function of a mental hospital is curative as in the case of any other hospital, and when the voluntary system of admission is extended to rate-aided cases, patients will, he believes, apply for treatment more readily and with more satisfactory results.

#### ROYAL SCOTTISH NATIONAL INSTITUTION, LARBERT.

The Royal Scottish National Institution for feeble-minded children at Larbert, the reconstruction of which has recently been completed, was visited by a large number of people on May 30th, when the Duchess of Montrose, one of the vice-presidents of the institution, was present. The institution, which was founded in 1862 for 28 mentally defective pupils, now accommodates about 500, and employs a staff of 100; it also has a long waiting list. The visitors were welcomed on behalf of the directors by Sir Alexander Gracie, who stated that in recent years it had been realized that institutions of this sort suffered from one great difficulty in the fact that the after-care of the pupils did not extend beyond 21 years of age. With increased knowledge and experience, however, the public were realizing that this was a mistaken policy. The Duchess of Montrose delivered an address upon the problem of the feeble-minded. No working-class mother, however devoted, could, she said, hope to give her afflicted child the advantages which this institution provided. When the small mental faculty possessed by each child was remembered, it was surprising how much they could be taught by the never-failing patience and devotion shown by the teachers. Mentally defective children could be well trained even if they could not be cured. The problem of the feeble-minded, apart from the insane, was a modern one. About fifty years ago a man was either considered sane or insane, and at that time mental deficiency was deemed insufficient reason for admission to an asylum, and the matter was largely ignored until the rapid increase of mental defect took place during the latter years of the nineteenth century. The Royal Commission appointed in 1908 to inquire into the care of the feeble-minded revealed a very pitiable state of affairs. Figures had been produced showing that one-quarter or one-fifth of all workhouse inmates, one-half of the girls in rescue homes, one-tenth of all prisoners and vagrants, and the majority of the inmates of homes for inebriates, were feeble-minded. Such facts cried for a remedy, yet even now the State only concerned itself with mental defectives up to the age of 16 or 21; after that they were turned loose on the community. This was, on grounds of social economy, a short-sighted policy, for the majority passed to the workhouses, gaols, and rescue homes, where they had to be maintained. A far better solution of the problem would be through permanent care in industrial colonies. In such places all grades of the feeble-minded could, according to their capacity, continue their work in the house, the garden, or on the farm or in industrial shops, and in this way they could become to a large extent self-supporting. It was satisfactory to know that the Scottish Council of Women Citizens' Associations was taking up this question with energy, and making an appeal throughout Scotland for a sum large enough to start a Scottish industrial colony. It was much to be hoped that such a colony would be started soon, so that the children trained at Larbert might be passed on there at the age of 16 or 18. At the Industrial Colony at Sandelbridge the inmates now numbered 300 persons, leading a contented and happy life, doing the work of the colony for themselves, and thus rendering it partly self-supporting. No scheme for social betterment was more urgent in Scotland than this, and for its initiation a sum of £40,000 was necessary. The party subsequently visited the institution, where children were seen busy at such occupations as rug-making, darning, and machine

knitting. Classes of girls were making rush baskets, mats, and shopping bags, and in other workrooms girls were being trained in simple household duties, while the boys were engaged in tailors' and carpenters' shops.

## Ireland.

#### MEDICAL MEETING IN COUNTY WEXFORD.

A MEETING of the County Wexford medical practitioners was held recently in Enniscorthy, with Dr. G. E. Greene in the chair. Letters were read from Dr. P. A. Doyle, with regard to medical fees in accident cases, and from Dr. Brady, in relation to attending and giving evidence in State prosecutions. The pension clauses of the Local Government Acts, 1919 and 1925, were discussed, and, the Irish Medical Secretary having written to say he was taking legal advice in connexion with the advantages and disadvantages of both Acts, it was decided to postpone further consideration of the question until June 17th, when a joint meeting of the medical practitioners of County Wexford and County Wicklow would be held and Dr. Hennessy would be invited to attend. The meeting decided that it would be inadvisable to pronounce any opinion on the interim report of the Committee of Inquiry into Health Insurance and Medical Services until the issue of the final report. Drs. Dowse, Greene, Hickey, Murphy, and O'Brien were appointed as representatives to attend a meeting of delegates when summoned in connexion with the consideration of the reports of the Committee of Inquiry into the medical services. Arising out of a discussion of the resolutions relating to the duties of county hospital surgeons, passed at the meeting of the Irish Medical Committee held on May 11th, it was resolved that the notice of motion to rescind them be put on the agenda for the next meeting of the committee, so that they might be further and more fully discussed. Drs. O'Brien and Dowse having brought before the meeting the overcrowded state of the Wexford County Hospital, it was decided to ask medical officers to make inquiries from Dr. O'Brien and the secretary of the County Wexford Board of Health if beds were available before sending cases for admission, except in cases of urgency, which would be admitted at any time. Dr. Hickey moved, Dr. Lawler seconded, and it was unanimously resolved, to tender heartiest congratulations to Dr. Thomas Hennessy on his election to Dail Eireann, where his presence and intimate knowledge of the requirements of the medical profession would enable him to be of greater service than ever in furthering its many interests. The honorary secretary reported that a sum of £44 16s. was collected in County Wexford for the Organization Fund of 1924.

#### PATHOLOGICAL LABORATORY FOR MENTAL HOSPITALS.

The suggestion of the Minister for Local Government regarding the establishment of a pathological laboratory at Grangegorman Mental Hospital, Dublin, was the subject of a special report by Dr. J. O'C. Donelan, the resident medical superintendent, which was submitted at a meeting of the joint committee of the hospital. In his report, Dr. Donelan stated that the pathological laboratory at Grangegorman might be developed into a valuable centre for work and study, but he did not think that there could be much field for it as a teaching centre in the immediate future, as there were at present three excellent schools of pathology in Dublin. The scheme of creating a central laboratory for all the mental hospitals of Ireland would, to be of any use, involve the appointment of a really first-class man, who had proved himself to be devoted to pathological work, and who would necessarily command a substantial salary. He would also require one, or probably two, assistants. The expenses would be considerable, and although Dr. Donelan was not without hope that something of this kind might ultimately be attained, and ought to be aimed at, he believed that the best results would be obtained by beginning on a small scale and developing as circumstances indicated. It was decided to send a copy of the medical superintendent's report to the Local Government Department for an expression of the department's views, and to defer action.

## Correspondence.

### PERINEAL DRAINAGE AND PROSTATECTOMY.

SIR,—Mr. William Billington's letter (June 20th, p. 1159) recalls some papers I published over sixteen years ago in which an attempt was made to combine perineal drainage with suprapubic prostatectomy by "a simplified method of performing prostatectomy by the combined routes."<sup>1</sup> I reported the results of 23 operations done by the method to the 22<sup>e</sup> Congrès de l'Association française de chirurgie, 1909. The operative mortality in my small number was on a par with Young's 112 perineal cases—that is, none; and a study of the relativity of 4,539 perineal to the 1,932 suprapubic cases collected in my list is greatly in favour of the perineal route.

It seemed to me that an operation combining the advantages of both operations might lead to a better surgical success on the whole. I confess, however, that not many have tried the "combined method" of operating except the few who have seen it done; but three well known surgeons who were in difficulties in enucleating hard small prostates by the suprapubic operation until they were informed of the combined method used it with immediate success.

The length of time is not often less in performing the "combined method" than the suprapubic operation by itself. The apparent paradox is due to the fact that establishment of perineal drainage takes less than a high fraction of a minute to form, and subsequent enucleation of the prostate with two forefingers working *en rapport* secures rapid removal even in difficult hard cases.

It seems to me to be more than important to find out by careful inquiry why the mortality of the suprapubic operation by itself is higher than that of the perineal by itself.

The goal of operations is a recovery rate of 100 per cent., and when it is not gained we have to look out for weakness in the minute details of the plan of attack or of unsound judgement in the evaluation of diverse resisting defensive forces located within the camp—the patient.

Another point in Mr. Billington's letter which is of interest is that of drainage of the bladder after internal urethrotomy. I had the privilege of sitting next to that wise surgeon Mr. Pridgin Teale at Leeds during a function not long after I published a note on "Two cases of urethrectomy for traumatic stricture,"<sup>2</sup> in which I used neither drainage of nor a catheter tied in the bladder; he remarked that he always drained the bladder in cases he had operated on, and while accepting gratefully, I hope, his warm congratulations upon my daring, I felt a sort of chill from which I never recovered, for I always slipped a catheter into the bladder after that privileged occasion.—I am, etc.,

Llechryd, Cardiganshire, June 22nd.

JOHN LYNN-THOMAS.

### DISEASES DUE TO FASHION IN CLOTHING.

SIR,—I have been interested in the correspondence regarding my article (May 23rd, p. 960) on diseases due to fashion in clothing, particularly in the letter by Dr. W. Elder (p. 1152). I have, of course, seen cases, in patients of various ages, of erythema ab igne, also called "erythema a calore," on the legs from sitting in front of the fire, on the abdomen or elsewhere from the repeated application of hot compresses or hot bottles. Some persons seem to be more liable to develop this kind of erythema (and the resulting cutaneous pigmentation) than others, and the hypostatic element in the legs—notably when there are varicose veins—doubtless plays a part; I have, however, also seen it on the upper extremities. It has, in all the cases that I have met with, been distinguished by its more or less reticulate pattern (erythema reticulatum), like that seen in livedo reticulata. Probably the capillary circulation in some persons is more disturbed by heat, in others by cold. Perhaps the subjects of livedo reticulata (to which

more than one member of a family may be specially liable are unduly affected both by heat and cold.

The reticulate pattern above referred to was not apparent in the cases I discussed as "chronic erythema of the legs" and they were certainly not examples of erythema ab igne (a calore). I have never heard of chilblains being produced by the action of heat without cold. Chilblains are in fact, a kind of erythema a frigore, though every sufferer knows that the improper application of heat, after exposure to cold, may favour their appearance. I should therefore not be surprised if "roasting" the legs in front of a fire after exposure to cold favoured the appearance of the erythema of the legs about which I wrote. But heat is probably no more the cause of that erythema than it is of chilblains.

On the other hand, true erythema ab igne of the legs was certainly not very rare in England before short skirts became the fashion, and was not confined to elderly individuals with varicose veins. The curious reticulate appearance puzzled, as it still does, medical men from the Continent, where the open fireplace is much less used than it is here. Some women thus affected admitted that when seated alone in front of the fire they raised their skirt to the knees to warm their legs better. But men were and are, also occasionally affected in spite of their trouser-covered legs.

From some remarks which I have seen elsewhere on the subject of my paper there seems to have been confusion with a condition of chronic non-erythematous swelling or thickening of the soft parts about the ankles in women. That condition is quite distinct from the erythema with thickening to which I alluded; it is, I believe, sometimes associated with premature menopause and thyroidal insufficiency. On the other hand, cases similar to those to which I referred were evidently recognized by Professor V. Klingmüller of Kiel, and were described by him as "chilblains of the legs" in 1921.<sup>1</sup> His cases occurred in well nourished girls and young women, and he recognized the part played by short skirts and thin stockings in the etiology. He obtained good results from local turpentine injections.

In regard to Dr. Elder's remarks on chlorosis I do not think that much stress should be laid on improved general hygiene in food, ventilation, and open-air exercise as causes of the disappearance of the disease; it would only serve to divert attention from the real culprit (corsets), and mask the heinousness of the crime. Probably constipation was much overestimated as a factor in chlorosis; chalybeate treatment was often successful in spite of constipation. "Healthy" open-air exercise did harm to chlorotics when the real cause was unknown, and the very unhygienic method of keeping to bed or living in a basement, without having to climb up stairs, helped much, in conjunction with chalybeate treatment. I have Dr. J. H. Abram's permission to refer to a recent case of genuine typical chlorosis in a girl living in good surroundings (communicated to the Association of Physicians on May 30th). A fatty tumour weighing 1½ lb. had been removed from the side of the abdomen, and she had been tight-lacing because of the swelling. Complete recovery occurred in three or four weeks.—I am, etc.,

London, W.I, June 20th.

F. PARKES WEBER.

### APPENDICITIS.

SIR,—As it happened that I was the first<sup>2</sup> British surgeon to practise and advocate immediate operation in appendicitis, I was much interested in reading two addresses published in the BRITISH MEDICAL JOURNAL of April 18th in which, after the first twenty-four hours, expectant treatment was duly extolled. After reading these my sense of proportion was somewhat alleviated by perusing the last paragraph of the report of a discussion on the mortality of appendicitis at the Surgical Section of the Royal Society of Medicine, in which one of the speakers, in his reply, said: "If expectant treatment were generally adopted by

<sup>1</sup> BRITISH MEDICAL JOURNAL, October 3rd, 1906, p. 922.  
<sup>2</sup> Ibid., November 8th, 1902, p. 1523.

<sup>1</sup> Arch. f. Derm. u. Syph., Berlin, 1921, cxxxv, p. 255.  
<sup>2</sup> Philadelphia Med. Journ., December 2nd, 1899, and Lancet, February 3rd, 1900.

hospitals there was a danger that the practice would extend to those treated elsewhere." Yet I should have felt more satisfied if, instead of the term "danger," he had substituted "certainty." His closing phrase—"The surgeon who would, if and when necessary, operate"—makes me rigid. Without the introduction of the sense of sight, I am, after thousands of appendicectomies, unable to locate the "if" or the "when," but have found<sup>1</sup> that in a huge proportion of cases the "wait and see until things settle down" slogan results in adhesion formation running amok, the patient becoming saturated with deadly toxins, the lymphatics and veins and liver becoming stuffed with bacterial thrombi, and the intestinal walls becoming putrid with septic infiltration.—I am, etc.,

Buenos Aires, May 11th.

JOHN O'CONAN, K.B.E., M.D.

#### MENTAL SHOCK AND THYROID DISEASE.

SIR,—Colonel McCarrison, in his lecture on some problems of thyroid disease (June 13th, p. 1065), did not mention the possible nervous origin of goitre. Last year I had a case in point—a married woman who took fright on seeing her son being pursued by an older boy, who evidently intended to chastise him severely. In consequence she suddenly developed a most marked goitre, non-exophthalmic in nature, which to a certain extent persists. The endocrine glands being correlated, is it not possible that fear may have so acted on the suprarenals as to affect adversely the thyroid, thus altering the ionic balance; or that, alternatively, the occurrence was an example of anxiety neurosis, so called, acting through the sympathetic?

Recently I had a case of goitre, developing in a primipara three months after birth of her child, which rapidly resolved, the sole treatment being a pinch of iodized salt taken with each meal. As there were no symptoms of hyperthyroidism, iodine was not contraindicated, and I have never seen a goitre disappear so completely in so short a time.—I am, etc.,

JOHN B. PRUMMER, M.B., Ch.B., D.P.H.

Cowdenbath, June 13th.

#### BRITISH MEDICAL WOMEN FOR INDIA.

SIR,—I have read recently in the JOURNAL at least two letters which suggest that in India there is unlimited scope for the superfluous medical women in England, if only they will grasp their opportunity. I should very much like to know if this is really the case.

Undoubtedly the mission hospitals can absorb many medical women, and for those who feel that they can conscientiously undertake it, and who can live on very small pay, such work cannot be too highly recommended. The Women's Medical Service for India (Countess of Dufferin Fund) is a small service, and I have been told that it is being gradually "indianized."

With regard to other work, I see in the *Pioneer* and *Statesman* newspapers advertisements for Indian sub-assistant surgeons, but I have never seen one for a European woman doctor. I have worked with Indian women doctors and know how capable some, at least, are. I have also visited one flourishing medical school for women and know of others; but the supply of Indian women doctors is steadily increasing.

I should imagine that in native States the Indian doctor would have preference over the European, and I was told by one doctor (European) that she had not found such service satisfactory on account of the difficulty of "getting things done."

About prospects in State service in British India I know nothing—I have seen no advertisements in the BRITISH MEDICAL JOURNAL, or elsewhere, of appointments.

Private practice, except combined with, or subsequent to, a public appointment seems out of the question. In most places European women are attended by I.M.S. and R.A.M.C. doctors, and the Indian women, purdah and otherwise, are so conservative that it takes years to gain their confidence. In South India a knowledge of several

languages would be of great assistance to anyone setting out "to help the Indian women."

This letter is the outcome of very limited experience in India; I hope it may elicit some real facts.—I am, etc.,

May 26th.

MEDICAL WOMAN.

#### INDIVIDUAL MEDICAL DEFENCE.

SIR,—In reply to Dr. Gillbard (June 13th, p. 1110), allow me to state that he seems to misunderstand the object of my query to Dr. Robinson. While it may be *ultra vires* for a defence society to prosecute one of its members before the General Medical Council, as Dr. Robinson states, I showed by an example (May 30th, p. 1021) that a defence society may prosecute a member of another defence society. In formulating the new British Medical Association scheme it may be thought wise to exclude any such prosecutions and confine it entirely to defence. Personally, I do not think this wise, but that is only a single opinion. The object of my query was to give the topic consideration. If Dr. Gillbard will turn up the SUPPLEMENTS for July 28th, 1906 (p. 98), and August 4th, 1906 (p. 126), he will see therein that the Central Ethical Committee reported to the Representative Meeting of 1906: "That it is absolutely necessary in the interests of the medical profession that the Association should take up cases of a penal nature before the General Medical Council as complainants," etc. The debate, in which Sir Victor Horsley took part, makes interesting reading. If my "naïve query settles" the new scheme, according to Dr. Gillbard, surely *a fortiori* the Association should have been "settled" in 1906.

The difficulty then and the difficulty now is that many members of the General Medical Council are also members of the British Medical Association. In time this difficulty may resolve itself along the lines suggested by Lord Justice Atkin in his address to the Middlesex Hospital Medical Society, when he said that "the question whether medical men might not fairly claim to have decisions affecting professional conduct made subject to some judicial investigation instead of being left to the decision of any tribunal which did not act upon legal principles and upon evidence which could be tested and controverted by cross-examination" (May 16th, p. 936). The New Zealand "E.R.A." cult case is a good example of a case affecting professional conduct tried before a high judicial tribunal.—I am, etc.,

Warrington, June 13th.

J. S. MANSON.

#### SICKNESS AND ACCIDENT INSURANCE.

SIR,—The recent liquidation of an insurance company issuing "sickness and accident policies" has brought home to many medical men the inadvisability of taking an insurance policy of any kind without obtaining independent and impartial advice such as the Medical Insurance Agency was formed to give.

This Agency, founded by the *British Medical Journal* and the *Lancet* in 1907, has never recommended the company in question, but is prepared to offer expert advice to, and to use all possible effort to assist, those members of the profession who have not previously made use of the facilities here provided for them.

An advertisement of the Medical Insurance Agency is published this week (advertisement page 5).—I am, etc.,

L. FENNIS-SCOTT,  
Secretary, Medical Insurance Agency,  
British Medical Association House.

June 22nd.

SIR,—From applications which have been received by the Medical Sickness, Annuity and Life Assurance Society, Limited, 300, High Holborn, W.C., it appears that a number of medical men are unfortunately involved in the failure of the Profits and Income Insurance Company.

The directors of the Medical Sickness Society (which was formed in 1884 by the late Mr. Ernest Hart on mutual lines, solely for the medical and dental professions) have carefully considered in what way they could best assist their colleagues in their present difficulty, and are prepared to give consideration to any applications which may be made to them. Inasmuch as the sickness premiums

<sup>1</sup> *Lancet*, September 5th, 1914.

charged by the Profits and Income were considerably higher than those charged by this society, policy-holders in many cases can obtain the same benefits from this society as those for which they insured in the Profits and Income several years ago without paying increased premiums. Naturally such applicants will now be desirous of ascertaining the financial position of any society or company in which they may desire to insure, so that they may be confident that their claims will be met.

So far as the Medical Sickness Society is concerned I would, with your permission, refer them to the advertisement page in this issue of the JOURNAL, from which they will see that separate funds exist for life assurance and for sickness and accident, invested in sound securities, properly vouched for.—I am, etc.,

FRANCIS J. ALLAN,  
Chairman, Medical Sickness, Annuity and  
Life Assurance Society, Ltd.

June 22nd.

### INMAN v. TANNER.

Sir,—In relation to the above suit (reported in your issue of June 20th), I feel it should be known that I received great kindness and loyal help from my professional brothers. The following gave valuable assistance and attended the High Court to give evidence on my behalf: Dr. Cammidge, Dr. Sidney Phillips, Professor Mclean, and Dr. Worster-Drought; and many others, including Sir William Willeox, were prepared to do so also.

It was a splendid example of loyal fraternity, and I am deeply grateful.—I am, etc.,

HERBERT TANNER.

London, W., June 23rd.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The House of Commons has this week passed the Finance Bill through report and read it a third time. It has also debated foreign affairs. Next week it will probably discuss the Contributory Pensions Bill and unemployment.

At last week's meeting of the House of Commons Army Committee Sir Richard Luce brought forward the question of the conditions under which medical men enter and serve in the R.A.M.C. The committee expressed sympathy and promised support.

### Income Tax Allowance for Wear and Tear.

A concession of importance to medical practitioners was obtained by Dr. Fremantle during the report stage of the Finance Bill. He moved, and the House accepted, a new clause declaring that—

Rules 6 and 7 of Cases I and II of Schedule D (which provides in connexion with the charge to income tax under that schedule of the profits or gains of a trade for the allowance of deductions in respect of the wear and tear of machinery and plant and in respect of expenses incurred in replacing obsolete machinery or plant) shall apply as if references in those rules to the profits or gains of a trade included references to the profits or gains, whether assessable under Schedule D or otherwise, of a profession, employment, vocation, or office, and, in relation to profits or gains assessable under some schedule other than Schedule D as if the provisions of the said rules were applicable to the tax under that other schedule.

Provided that where the profits or gains are not assessed under Schedule D the powers of the additional Commissioners, under paragraph (4) of the said Rule 6, may be exercised by the General Commissioners.

Mr. Guinness, the Financial Secretary of the Treasury, said the Government was glad to accept the clause which Dr. Fremantle had put down in consultation with the Treasury. It carried out the recommendations of the Royal Commission and extended the income tax allowance which had long been enjoyed by and machinery—an allowance which had long been enjoyed by and machinery—to professional people and employees who, in the opinion of the Royal Commission and the Government, were fairly entitled to the same advantage.

It was subsequently pointed out in the Lobby that under the new clause the medical practitioner will be able to obtain an abatement of income tax in respect of the upkeep and replacement of his motor car.

### Public Health Bill.

During the report stage of the Public Health Bill Mr. Herbert Williams moved a new clause, which also stood in the name of Dr. Fremantle. This clause applied to any room not already regulated under the Factory and Workshop Act, 1901, or the

Public Health (Regulations as to Food) Act, 1907, in which food is sold or prepared for sale, or stored or kept with a view to future sale. No room is to be used for such purposes if a sanitary convenience is in it or communicates directly with it, or if offensive odours therefrom can penetrate to it, or if the cistern for supplying water to the room communicates or discharges directly into any sanitary convenience. If any drain or pipe for the conveyance of sewage is in the room its inlet must be efficiently trapped. The room must not be used as a sleeping place and must not communicate with any sleeping place in the room. It must be ventilated adequately unless used as a cold store. The occupier is under an obligation to keep the room clean and to take reasonable steps to prevent the contamination of food therein, and the cleanliness of apparatus and utensils. Power is provided for the medical officer or sanitary inspector to enter and inspect any room to which these provisions apply. Food is defined as every article of food and drink used by man, other than drugs and water, and also flavouring matters and condiments.

The clause was accepted by the House and Government, and was added to the bill without a division. Any local health authority may now adopt and enforce it.

On a further clause dealing with the payment of "reasonable" wages to municipal employees, Mr. Jack Jones, in moving an amendment as to the pay of manual workers, said the medical officers of health laid down a rule that they must be paid a certain rate for their services; although the local authority to which he belonged did not agree, they felt compelled to pay it because the medical officers were strong enough to make them. The amendment was withdrawn, and the bill was reported to the House and read a third time.

### Births and Deaths Registration Bill.

The Births and Deaths Registration Bill, introduced by Dr. Fremantle, is to be withdrawn. After correspondence, the Minister of Health lately asked Dr. Fremantle to see, along with other promoters of the bill, the Registrar-General and a representative of the Home Office, for the purpose of agreeing on a basis of a revised bill that could be introduced next session as a private member's measure, with a prospect of the Government adopting it. The suggested conference has been held and a subcommittee has been set up on the subject, on which not only the Government departments concerned are represented, but also the Federation of Medical and Allied Societies, who are the original promoters of the bill, and the British Science Guild, which supports it.

### Nursing Homes (Registration) Bill.

Mr. Gerald Hurst has withdrawn the Nursing Homes (Registration) Bill on receiving an assurance from Dr. W. E. Elliot (Under Secretary of Health, Scotland), that the Government will appoint a Select Committee to go into the subject. Dr. Elliot pointed out that time was inadequate for the passage of the bill this session. Mr. Hurst recognized that the bill could not become law this session, but said it was supported by the great majority of nurses in the country. It aimed at preventing bogus institutions from defrauding the public.

### Public Health (Scotland) Bill.

The Public Health (Scotland) Bill was put down for report last week, but was crowded out by a debate on China. The Government does not intend to abandon it, but some considerable time may pass before it can be brought before the House of Commons. Dr. Shiels proposes to move an amendment to it.
